NEW YORK, June 25, 1887.

RAILWAY SPECIFICATIONS AND PROPOSAL FOR WINONA CITY RAILWAY COMPANY, WINONA, MINN.

DEAR SIR: We beg to submit the following estimate for the electrical equipment of the Winona City Railway according to the particulars and specifications received:

Length of line, 7 miles of single track, with 16 turnouts and 15 curves, and —— feet of double track, extending as per inclosed exhibit.

Central generating station to be at or near the east end of the line, at a distance of 100 feet to the nearest point of the road.

Gauge of track to be 3 feet 6 inches.

Kind of rail to be 27 lbs. steel tram.

Character of street to be dirt.

Make of cars, Brownell & Wight.

Number of cars to be equipped, 16.

Maximum number of cars in operation at any one time, 16.

Weight of car, 3,000 lbs.

Length of car, 12 feet.

Seating capacity, 18; maximum number of passengers to be carried, 40.

Size of car axle, 2½ inches.

Distance between center of axle and bottom of loaded car, 8 inches.

Diameter of wheel less flange, 30 inches.

Maximum speed required on a level, 10 miles.

Running speed per hour, 6 to 8 miles.

Road to be operated by overhead wires.

The cost of the entire electrical equipment of the road, based upon the foregoing details, would be:

Seven miles of special, hard-drawn copper wire, with double circuit, also double metallic main circuit, supporting brackets, insulators, etc., including poles and erection of the line, $1,600 per mile	$11,200
Sixteen turnouts and 15 curves, $50 each	1,550
Sixteen motor outfits, 7½ H. P. capacity and capable maximum speed of 10 miles an hour on a level, being placed on each car, mounted on double compression springs and centered on the axles, which are driven by means of pinions meshing into gears, both motors being controlled by single regulator switches, which may be operated from either platform, at $800 per outfit	12,800
Gears, pinions, trolleys, connecting and setting up same, turning off axles, mounting and shielding motors, $150 per car	2,400
Two dynamos of 5,000 watts capacity each, including base-frame and regulators	5,000
Total f. o. b., N. Y	$32,950

The figure quoted for the motor outfit is based upon the assumption that you are to furnish the cars, the trucks of which are to be delivered to us at any designated place in New York City. If it is desired that we furnish the cars, the figure given for this item would have to be increased by from $800 to $1,500 per car, depending upon the character of car desired. It is recommended that we furnish the running gears, wheels, axles and boxes.

We will also furnish, if desired, an estimate for a complete steam plant of the most approved pattern, suitable for operating the dynamos.

The line work will be thoroughly well done. The current is carried over double, ladder-like conductors, the main conductor carrying the greater part and the sectional or working conductor the smaller part. In this way it is impossible for any accident to the middle overhead wire in the street to disable the entire line, which is a matter of very great importance. Again, where there is an extension of the road or an additional number of cars, no change being necessary in this middle overhead wires, there is no stoppage of travel or falling off of efficiency. The current is taken from this overhead wire to the car by a very simple overhead contact, which runs with very little friction, and follows the line of the overhead wire without difficulty.

When a double-track system is used, a single wire only follows each track; but where a single track with double turnouts, two wires of the same potential are carried overhead, diverging at the switches. In this way all changing of the trolley, which is carried on the wire, is avoided when passing the turnouts. The size of this wire is independent of the number of cars operated, or the distance over which the line extends. The main current, however, is not carried by this small wire, but is carried by a main conductor running the entire length of the line, and supported directly on the poles in the same manner as a telegraph wire. The size of this wire depends upon the number of cars and the distance over which they are operated.

In attaching the motors to the cars we avoid as much as possible changing the character of the car and taking up any sitting or standing room. Belts, friction-ropes, sprocket wheels and chains are discarded entirely. The motor, of very powerful form and of very simple construction, is carried underneath the car. At each end of the motor it extends so as to grip the axle of the car, and is held in position by heavy iron caps. Inside of these are split liners to take up the wear. The axle is turned off to a smooth surface, and just outside the hangers and close to the hubs of the wheel are two split gears. These differ in character. One is keyed and bolted directly on to the axle, and is a fixture. The other is composed of four parts, two being inner webs, which are keyed on to the axle; the two outer ones form the geared section and are bolted together, and have corresponding webs projecting inwardly and fitting snugly, both on the outer edge and on the face of the webs, which are keyed to the axle. The outer and inner webs are held together partially by the method in which they are turned up, but principally by bolts passing through them, which work in curved slots. These then constitute adjustable split gears.

The cut gear wheels are of an especially fine grade of cast-iron, and have the same face as forged steel pinions carried by the armature shaft, which mesh into them. The teeth in these gears are of the involute cut, so that if the motor should be slightly moved to or from the axles the gears will still run true, with only a little more or less closeness of meshing. The pinions on the armature shaft are set so that the one is half a tooth in advance of the other. Ordinarily, it would be a very difficult matter to get the splines cut on both the armature shaft and the axle and in the pinions and gears so that they would mesh smoothly in running forward and backward, and it was for the purpose of getting rid of this trouble that the adjustable split gear was designed. It is now only necessary to key the two pinions, one fixed gear and the web of the other gear in position, without any regard to their meshings. The motor is then swung into position, the hangers made to engage the axle, the caps are put on, and the motor being moved forward and backward two or three times while the bolts of the adjustable are slack, this gear will assume a correct position. The bolts are then tightened up, and there is thus a nest of double pinions and double gears all meshing with absolute precision, no matter whether the motor runs backward or forward. The method of mounting produces a concentric motion, and by this means the driving and the driven axle are maintained absolutely parallel in two planes under all circumstances. Should it be desired we will submit estimates for the storage or conduit systems.

All rights of way must be obtained by the local company, and the process of erection of the line must not be handicapped by delays caused by the action of municipal authorities, nor will this company be responsible for any legal action involved in the procuring of these rights of way.

Drawings of any new cars to be submitted to us before construction, and any minor changes necessary made according to our suggestions, to enable the motors to be put in the most compact manner possible.

The terms of payment will be as follows: Expenses of one man to instruct employees, 60 days' satisfactory working.

Each company to give bonds for the faithful performance of its part of the contract.

Trusting that the foregoing will be satisfactory, and that we may shortly enter into an arrangement with you for the equipment of your road, we are

Yours very truly,
THE SPRAGUE ELECTRIC RAILWAY & MOTOR CO.
Per C. M. BARCLAY, Manager.

[Proposal holds good for 60 days.]

While this specification may cause all those who read it to-day to smile, it must be remembered that it was a very sober thing in those days, and represented the best judgment of those who had given most thought to the question.

Below is given another reminiscence of a later date which electric railroad men will be able to appreciate quite fully, since many of those who attend the Convention have had personal experience of it. Reference is made to the former prices of street railway material.

Many of those who equipped roads in the early days remember with sorrow the prices they had to pay for material far inferior to that now manufactured. These require no reminder, but those who came into the field later will doubtless be interested in comparing the figures which ruled then with those which hold now.

Shortly after the absorption of the Sprague Company by the Edison General, a reduction in prices went into effect. The new schedule dated from May 1, 1890, and in the following lists the figures in the first column were the prices holding before and those in the second column those holding after the date mentioned—the figures in all cases being net shop prices. To these 20 per cent. was added by agents in making up bids:

NET COST PRICE, LINE MATERIAL.

	Before.	After. May 1, 1890.
Rail bonds 30 in. long	$ .13	$ .09
Rail bonds 6 ft. long	.15	.13½
One mile single track, span work:		
Wood poles	947.50	925.10
Iron poles	2,917.50	2,949.10
Pole ratchets with bolts	.60	.51
Line insulators	1.25	1.08
Center curve insulators	1.25	1.16
5-16 inch galvanized strand	.07¼	.06
1 mile double track, span work:		
Wood poles	1,060.00	1,029.10
Iron poles	3,030.00	3,053.10
Wood poles set, painted, coned, shaved and one-half of number furnished with cross arms, pins and insulators	7.00	
Iron poles set with tops and cross arms, pins and insulators	30.00	
1 mile single track bracket work, wood poles		663.00
1 mile single track bracket work, iron poles		1,675.00
Brackets, per 100		3.75
1 mile double pole bracket work, wood poles		932.00
1 mile double pole bracket work, iron poles		1,944.60
Octagonal wooden poles		15.00

TURNOUTS.

Turnouts	49.25
Overhead switches	8.00
Pull-off brackets	1.35

CURVES.

Single track curves	55.75
Insulated eyebolts	1.00
Double track curves	87.50
Cross-overs	49.25

SUNDRIES.

Line cut-out boxes	6.75
Trolley line breakers	4.29

WIRING CAR HOUSE.

Each track for 5 cars	75.00
Construction wagon	75.00
Acute crossing	15.00
Right angle crossing	15.00
Insulated crossings, single track	20.00
Railway crossings	25.00

DYNAMOS.

No. 16, 40,000 watts	2,500.00
No. 20, 50,000 watts	3,000.00
No. 32, 80,000 watts	4,250.00
No. 60, 150,000 watts	6,700.00

STATION APPLIANCES AND LABOR FOR RAILWAY WORK.

No. 16 dynamo, complete	900.00
No. 20 dynamo, complete	975.00
No. 32 dynamo, complete	1,150.00
No. 60 dynamo, complete	1,500.00

If two dynamos were installed the net factory price was:

No. 16	1,620.00
No. 20	1,755.00
No. 32	2,070.00
No. 60	2,700.00

If three dynamos were installed, and at that time three was about the limit, the net factory price was:

No. 16	$2,295.00
No. 20	2,486.75
No. 32	2,932.50
No. 60	3,825 00

DYNAMO SPARE PARTS.

(One armature and one set of babbitt shells.)

For No. 16 dynamo	900.00
For No. 20 dynamo	975.00
For No. 32 dynamo	1,150.00
For No. 60 dynamo	2,325.00

COMPLETE CAR EQUIPMENTS, WITHOUT TRUCKS.

With one 15 H. P. motor	2,000.00
With two 15 H. P. motors	2,900.00

EXTRA CAR EQUIPMENTS.

1 set with each 10 cars	600.00

Extra car equipment parts consisting of 1 armature, 1 set field coils, 1 main gear, 1 intermediate gear, 2 pinions and 1 trolley complete.

If we add 20 per cent. to these figures, which, would give us the net selling price of material at that time, we will realize that the lot of the railroad manager who equips his road to-day is comparatively speaking a happy one, and yet there are compensating disadvantages continually threatening to creep in.

One of these is the electrolytic corrosion of water, gas and other buried conduits, for which the railroad company will likely be held responsible. While remedial measures are at hand they are expensive and at best are not radical. The damage that is stopped to-day at this point is liable to be transferred to another spot to-morrow, and do all we can, unless we revert again to the double trolley, electrolysis will continue its insidious work, perhaps slowly, but nevertheless surely.

Another danger which threatens the electric railway manager, in our larger cities at least, is that they will be compelled to place their trolley wires as well as their feed wires underground. This implies far more than the mere expense of the conduit. It means a reversion back to low potential distribution, which means a larger original investment, not only in copper, but, if long distances are to be covered, additional power stations with all that they imply both in the way of original investment and additional operating expenses.

LONDON NOTES.

(From our London Correspondent.)

HIGHER VOLTAGE INCANDESCENT LIGHTING.

A short time ago we referred to the partial introduction into the Bradford electric lighting system of incandescent lamps of a high voltage by Mr. Sydney W. Baynes, who was then the corporation electrical engineer of that town. Since then Mr. Baynes has left Bradford and taken up the position of chief electrical engineer to the St. Pancras (London) Vestry, which owns one of the most successful and extensive London installations. In his new district Mr. Baynes has, although he has been stationed there only a month or so, commenced arrangements with a view to supply 220 or 230 volt fittings. At Bradford he has had such lamps in constant use for eighteen months, and for the past seven months they have been installed in the premises of customers taking their supply from that system, with excellent results.

No alterations in the fittings or wirings were necessary. The ordinary tumbler switch has, he declares, with good porcelain cut-outs, well-insulated wire, combined with good workmanship, long since proved thoroughly sufficient and safe in carrying even a higher voltage than that he intends introducing at St. Pancras. Eight C. P. and even 6 C. P. lamps are upon the market with high voltages. Dr. J. A. Fleming, writing to the London *Times*, recommends that all fittings used in houses, even on the present systems of supply, should be so made and tested that they can stand 200 or 220 volts pressure with safety, as they are all exposed to the chance of having to bear such pressure between some portions of them.

In the St. Pancras system no sweeping change of voltage is contemplated, for consumers already supplied at 110 volts will continue to receive that voltage, and it is optional for them to change if they consider the lighting obtained from the higher voltage to be more satisfactory. Where Mr. Baynes has previously worked the system, he has had consumers owning two distinct sets of premises, one having 230 volt and the other 115 volt lamps. The result of such trials has led to the replacement of the low voltage lamps with higher voltage.

STORAGE BATTERIES—II.*

BY H. A. EARLE.

There are many ways in which a specification can be framed so that a battery of the exact size required is obtained, and there is no doubt that it is most satisfactory to all concerned if the exact capacity in ampere hours is specified, and the final voltage of the complete battery at a given rate, the number of cells being omitted. Under these conditions, if the individual cells are discharged down to a low voltage, more cells would be required, but each additional cell on a 100-volt circuit adds 2 per cent. to their number, and correspondingly increases the cost of a battery composed of cells of a given size. On the other hand a low voltage per cell on discharge enables—up to a given limit—the number of plates per cell to be reduced, and the cost of cell as well. In a competitive tender the manufacturer would therefore work out the cheapest arrangement, and I find that this would not admit of the individual cells being discharged to too low a voltage, and that the purchaser would obtain exactly what he required at the lowest price.

The actual number of regulator cells is of small moment to the user, and the additional number required, when the individual cells are discharged down to a voltage of 1.8, in place of, say, 1.9, is only two in a 100-volt battery.

When tests are made to check the efficiency and capacity of a battery, we can place no reliance on the figures obtained from a single charge or discharge. As a rule, no two consecutive discharges from a cell are identical, even when the same is discharged with the same current, and down to the same voltage; every discharge being greatly influenced by the previous treatment. The table given below clearly demonstrates this:

Charge.							Discharge.							Percentage of efficiency.	
Charge, No.	Duration of charge		Rate in amperes	Volts at end of charge	Ampere hours	Watt hours	Discharge, No.	Duration of discharge		Rate in amperes	Volts at end of discharge	Ampere hours	Watt hours	Ampere hours	Watt hours
	Hs.	M						Hs.	M						
1	3	00	15	2.68	45	..	1	7	30	15	1.68	113	218	....	....
2	9	45	"	2.68	146	..	2	7	45	"	1.70	116	227	79.4	....
3	12	00	"	2.68	180	428	3	9	25	"	1.70	141	278	78.3	64.9
4	12	30	"	2.67	187	443	4	9	50	"	1.70	148	285	79.1	64.3
5	8	45	"	2.50	131	299	5	8	40	"	1.70	130	255	99.2	85.3
6	11	15	"	2.40	169	399	6	9	35	"	1.91	144	274	85.2	68.7
7	11	15	"	2.38	169	398	7	9	32	"	1.915	143	276	85.2	69.3
8	10	35	"	2.136	159	324	8	9	15	"	1.90	139	273	87.4	84.2
9	10	35	"	2.333	159	375	9	9	10	"	1.90	138	264	87.4	70.4
10	10	15	"	2.333	154	361	10	9	00	"	1.90	135	265	87.6	73.4

This table is in no way intended to be a guide as to what can be obtained in efficiency tests, but is merely to show the irregular nature of results obtained with slight variations in time and maximum voltage of charges; the rated capacity of the cell was 15 amperes for 10 hours, or 150 ampere hours.

Charge No. 1 we can omit, as this was given to complete the formation of the cell.

Charge No. 2 was for a similar purpose.

Charge No. 3 was continued, as were also charges 1 and 2 till the voltage had practically ceased to rise; a high voltage on charge gives a good return in ampere hours on the discharge, but if a cell is forced to its maximum capacity we obtain a poor return in efficiency.

Charge and discharge No. 4 are very similar to No. 3.

Charge No. 5 was stopped when the E.M.F. had risen to 2.5 volts and 30 per cent. less ampere hours had passed through the cell. Studying the figures up to the end of charge 5, it would have been practically impossible to assume what was going to happen on discharge No. 5; on taking this discharge, we obtain 20 per cent. increase both in ampere-hour and watt-hour efficiency, and the very high percentage of the former, namely 99.2 per cent., points to the fact that peroxide, which had been previously inactive, was reduced. The first five discharges, you will note, were all taken down to 1.70 volts; this cell had never been used before, so we have its history up to the 10th discharge in the table—the strength of acid at end of charge was practically 1·300 specific in every instance.

Charge No. 6 was only continued to 2.40 volts, but it required 2½ hours longer charge to reach this voltage than it previously did on charge 5 to reach 2.5 volts, and this was, without doubt, due to the good service rendered on the last discharge.

The remaining charges and discharges show that the highest efficiencies are obtained when the cell is not charged up to a high voltage, and if worked within reasonable limits, 90 per cent. in ampere hours, and about 80 per cent. in watt hours, can be obtained with the cell in question when in good order.

Usually efficiency is not of great importance, for, presuming a central station battery to give one-tenth of the total supply, a variation of even 10 per cent. in efficiency would only represent 1 per cent. variation in the total output; but the time may come when batteries are so cheapened and perfected that they supply the whole demand of our station, and their efficiency will then be one of importance, and we may be confronted with specifications as strict as those now framed for dynamos.

The strength of acid solution to be used in a cell is an important point. In the first place, this greatly influences the voltage, as we have seen from Fig. 3; it has also a great effect upon the life; besides this, in strong acid the plates sulphate more readily, and the sulphate is more difficult to reduce; it is therefore necessary to carry out most careful tests to ascertain what strength of acid should be used in each type of cell.

Curves for four temperatures in degrees Centigrade.

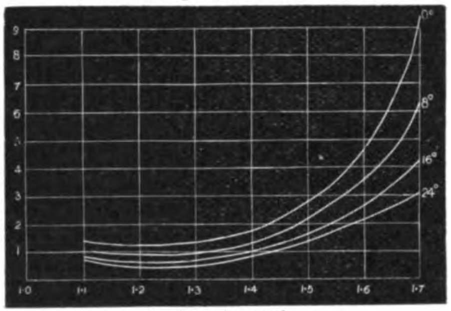

FIG. 4.

The resistance of acid solutions of different strengths is also a most important consideration, and on Fig. 4 four curves are shown giving its resistance at 0°, 8°, 16°, and 24° centigrade. Taking 16° centigrade as a mean working temperature, it will be noted that acid of about 1·250 specific gravity has the least resistance, and it might be assumed, therefore, that this was the best strength to work at, but we must bear in mind that this strength does not give us the highest voltage; and, moreover, the gravity gradually falls as the cell discharges, and when working with this strength we have falling voltage on discharge, and at the same time increasing resistance of the electrolyte; no fixed law can be laid down, as each type of cell requires a given strength for best results.

Immediately upon commencing our research with a view to ascertain the proper strength of acid, we find that we are confronted with another problem of great interest, which is, that different strengths give us different capacities from our cell. Fig. 5 gives two most interesting and instructive curves taken from two cells of the chloride type, one with positive and negative plates of .24 of an inch thick, curve A, and one with positive and negative plates of .4 of an inch thick, curve B. Each cell was discharged at a rate equal to .45 of an ampere per pound of plate. The rate per pound of active material is nearly the same for each cell, though perhaps slightly higher for the thinner plates. The rate of discharge per superficial area was, therefore, approximately 40 per cent. greater with the thick plates than with the thin.

The curves give the yield in ampere hours per pound of active material with different strengths of acid. Considering the thin plate curve first, we find that with acid of 1·070 we do not obtain more than about 3 per cent. of the maximum capacity; from this point to 1·230, at which point we obtain the maximum capacity, it rises very rapidly, each addition of 1 per cent. to the sulphuric acid present in the electrolyte giving an increase of about 1 ampere hour capacity per pound of peroxide; from 1·230 to 1·500 it falls as rapidly almost as it rose, and at the latter figure we obtain only 16 per cent. of the maximum.

Taking the thick plate curve: At 1·040 specific gravity we obtain about 6 per cent. of the maximum capacity, and it rises till 1·270 is reached; it then falls rapidly, and at 1·500 the output is practically *nil.*

Considering these two curves, we note that the thin plates give as maximum—

15 ampere hours per pound of peroxide and spongy lead, or

30 ampere hours per pound of peroxide alone, or about one-third of the theoretical value.

The thick plates on the other hand give

10 ampere hours per pound of peroxide and spongy lead, or

20 ampere hours per pound of peroxide alone, or about one-fifth of the theoretical value.

The natural question is, why is this the case? Also, why are the thick plates the best with very weak acid? and why do they give such a much poorer return with acid of the strength usually employed? I consider that up to the point at which the curves cross the better result obtained from the thick plates is due to the fact that on completion of the charge in weak acid the active material is saturated with strong acid and the quantity contained in the same would be greater with the thick plates than with the thin, and they would therefore give a better output with weak acid than the thin plates. Their increased thickness, however, is of no advantage with acid of the ordinary strength, when out capacity is chiefly dependent upon the penetration of the acid; if we study the portion of the thick plate curve between 1·150 and 1·400 specific gravity, and compare it with the thin plate curve, we find that the capacity is practically reduced inversely as the thickness or weight of the plate, and the rate of discharge of the superficial area. Quite apart from the question of the proper thickness of the active material, we can see at a glance that very different capacities are obtained with different strengths of acid.

On the top of the same Figure the mean volts during the discharge are given; these, it will be seen, rise steadily as the strength of the acid is increased; a striking feature is that the curves of voltage cross at the same point that the curves of capacity cross. Upon consideration we come to the conclusion that this is what would be expected, as the rate in amperes on discharge was the same in every case, and an increase in ampere hours per pound of material means a longer time to complete the discharge; and we see from Fig. 2 that the greater the length of the discharge, the higher the mean voltage.

It is the manufacturer's business to make as good a cell as possible, but when it leaves his hands it is judged by the service it renders during its life; this depends to a very great extent upon the treatment it receives. In the first instance purity of the electrolyte is essential; brimstone acid should be used, as this is the least likely to contain foreign substances; if this is diluted on the spot, the water must be pure, preferably rain, or if possible, condensed water.

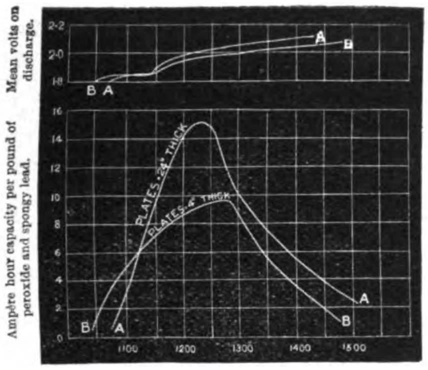
With regard to the first charge of the battery, it is generally imperatively stated that this must commence immediately upon the acid being put into the cells; this is no doubt necessary with imperfectly formed pasted plates, or with plates which have been for some time exposed to the air, as they would readily sulphate, and require a considerable time to reduce; but positive plates which have been fully formed, and negatives in good condition, are very slightly affected.

---

* Paper read before the British Association at the meeting September 11-17, 1895.

Fig. 6 gives five curves, which I have prepared in order to show results obtained from plates in different conditions, some having been left standing in the acid, while others were charged.

Curve A shows the specific gravity of the acid in the cell, in which the plates were allowed to stand for 22½ hours without being charged. During this period it remained absolutely constant, sulphation was therefore absent. The charge was then commenced and continued for eight hours; a rise in specific gravity took place, raising the electrolyte to a gravity above that at which it was put into the cell, which showed that sulphate was previously present in the plates.



Specific gravity of electrolyte at end of discharge.

FIG. 5.

Curve B shows what happened in another identical cell; directly the charging current was started the gravity fell rapidly. This, I presume, is due to the formation of oxide of lead from the pure lead remaining in the active material, and this is sulphated before becoming peroxide of lead. The current throughout the charge was kept constant, and from the curve we see that practically the same number of ampere hours were expended during the fall as during the rise; the specific gravity in this instance also rose slightly above its initial value.

The plates in curve C, which had been standing, sulphated slightly, and reproduced, on being charged, to a small extent a similar curve to B, and the plates (curve D) which were charged at once give a very small fall, but a considerable rise, showing that sulphate was present in the plates.

Curve E is for plates which stood before being charged, and in this instance we notice that no sulphation took place, and that they gave a small fall and rise.

My chief object in giving these curves is to demonstrate how very slight differences can give considerable variations.

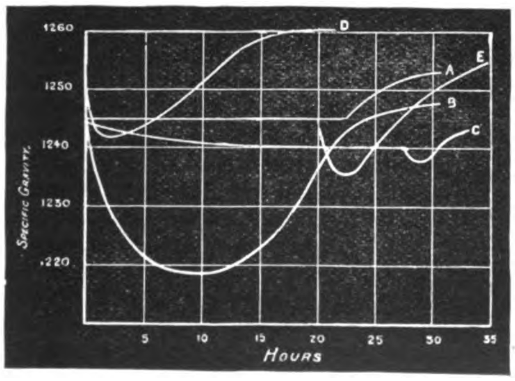


FIG. 6.

To return again to the treatment of cells. The chief causes of destruction are too prolonged, or excessive rates of discharge, insufficient charging, overcharging, long periods of rest on open circuit without charging, and allowing cells to remain after complete discharge for many hours before recharging. There is also another point which is worth mentioning. Frequently through undercharge or over-discharge the plates become heavily sulphated, the cells no longer give their proper output, and the specific gravity of the elecltrolyte falls considerably; of course, a prolonged charge will put this right, but frequently it is assumed that, as the specific gravity is low, the acid merely requires strengthening, and this is done with the best intentions; the fault is, however, aggravated, and the plates sulphate more heavily than before. I found on one occasion that acid had been periodically added, and the specific gravity rigidly maintained at 1·200, the charge being always stopped when this strength was reached; the cells were naturally working badly; a prolonged charge was accordingly given, and this raised the strength of the electrolyte as high as 1·450 in some cells, which was a clear indication of what had been done. We find, therefore, that a multitude of causes influence the working and life of storage batteries, and that many of these can be varied at will; the problem, therefore, is to combine all useful effects, that we produce the best possible article with due consideration at low cost.

It would be a natural question to ask, What do you consider the best possible article? and this is easily answered. In a secondary battery we have lead, sulphuric acid solution, and the resultant compounds, and nothing else.

The ideal cell is one that is indestructible, and this being given, the first cost and weight, if kept within reasonable limits, are of little moment.

At the present moment the life of a cell is its value, and all types are constructed with the knowledge of certain death, and in most types this lingering death is provided for, for we find at the bottom of the boxes a sufficient space to act as a receptacle for the deposit from the disintegrating plates; in other types, where the active material is held permanently in position disintegration still goes on, with consequent loss of contact. Now this disintegration is what we have to stop; the deposited disintegrated material is as good as ever, for nothing is wasted, and provided it were held in perpetual, firm, and good electrical contact with the frame, in such a manner that the free circulation and penetration of the acid were not hindered, and the internal resistance were not unduly increased, we should have produced an ideal and indestructible cell.

I have brought to your notice only a very few of the many interesting features in connection with secondary batteries, and these only in a most superficial manner; I have, however, endeavored to give a general outline of results obtained in practice, and have not entered into a discussion upon other more serious questions. Many conjectures arise in one's mind when considering the causes of different effects, and each point requires much time and study in order that a fixed law may be deduced from the results obtained; and again the results of tests are often so conflicting, and depend so much upon very small differences of condition, that it is by no means an easy matter to arrive at the truth.

ARE WE LAYING TOO MANY MILES OF TRACK TO REACH A FEW PEOPLE?*

BY W. W. COLE.

It is an established fact that as the mountain would not go to Mohammed, he had to go to the mountain. The fact is just as self-evident in the location of track, that if you stop one block from where the dividing line comes, between the settled district and the open field, the people will walk that one block to the cars; and the maintenance and operation of 1,500 feet of track for one year on a fifteen minute headway, at nine cents per car mile, means the interest at 5 per cent on $26,864, or $3.68 per day. It can be readily seen that with many lines extended just beyond the line of population the road has extended just beyond the line of dividend. It is conceded by all that when a new line is constructed we have to educate the people to ride, as they have become accustomed to depend on their horse or bicycle or to walk. Now, if we extend our lines beyond the population, we immediately become professors of education, as we must not only educate the existing population to ride, but must educate the people to build on the open territory and educate people to move into the houses built. If we keep within the lines of existing population, we have the advantage of a general located on an eminence—we can wait and see which way the population army moves, and then we make no mistake in our extension. In other words, the railroad is practically the army sutler, and there is no instance where the sutler led the army.

There is no denying that a railroad extended into open territory will increase the value of real estate, and eventually build it up; but in the meantime we are wearing out rolling stock and track for the owners of real estate, and should receive a bonus sufficient to carry the road until the open territory is sufficiently populated to support a road.

It is the general experience that by the time the fields become populated the rolling stock must be replaced and the track repaired, or we practically build a new road to suit the new condition, and outside of the benefit to the real estate owners, we only get our returns when the new road is built for the actual needs of the existing population.

A road built in an unpopulated district has to contend with more dust and mud upon its rails, which means wear and tear, and without sewers there are bound to be places in the track where it will be covered with water, which is deleterious to motors, trucks and car bodies.

We will cite as an illustration a city of 40,000 inhabitants which has twenty miles of track; five of the city lines extend 2,112 feet beyond the settled territory, or two miles of track with but little traffic. Taking an average of ten cities of 40,000 population, the riding per capita is forty-six times per year. This would give in gross receipts $92,000; operating expenses 70 per cent. of gross receipts, or $64,000; and $27,600 net receipts. The average road is bonded at the rate of $30,000 per mile, or $600,000 for twenty miles of track. The interest at 5 per cent. would be $30,000. This would show a deficit of $2,400 in interest.

Now, in this city of 40,000 inhabitants we have two miles of track operated and bonded that for the present we get no returns from, as it was built to promote the building of the city at different points; and like the man who has lived a good life on earth, we are looking forward to a future reward, but the man is invariably dead when he receives it, and the results on street railroading show that they are waiting for the sound of the horn in the hands of the receiver.

In this city of 40,000, if but eighteen miles had been built and bonded for $540,000, with an annual interest of $27,000, we could have shown at least $600 surplus, and with the modern methods of increasing traffic, this surplus could undoubtedly be increased to pay the stockholders a fair rate of interest if eighteen miles were built instead of the twenty.

If for obvious reasons it becomes necessary to extend the track beyond the populated limits, care should be taken to focus the promoting energy upon one line, and to extend no other lines until the one so extended has been so populated that that line shall be self-supporting, as with the extension of several lines in different parts of the city the various interests become separated and each line so extended only receives a very widely scattered population that must take years to promote into a paying territory.

Precaution must be observed in running out suburban lines for park and pleasure resorts, as we can only count on three months of pleasure travel, and a line built for pleasure travel only is apt to prove a problem with an unknown quantity. On the other hand, all parks and pleasure resorts introduced along existing lines, even though built at a considerable expense, if properly managed, will prove a booster to the net receipts of the lines favored.

In locating pleasure resorts, if possible they should be placed on lines connecting two towns, as then you promote traffic in both directions, and are not to a large extent paying for an empty mileage in one direction; and you are also promoting traffic to the thinly populated section of your road. To clinch my argument, I will quote from an editorial in the *Street Railway Journal*: "That the total street railway mileage of the United States is approximately 6 per cent. of the steam railroad mileage. About 6 per cent. only of this mileage is at present in the hands of receivers, as against about 25 per cent. of the steam railroad mileage. The gross earnings of all American street railway properties are probably slightly less than 15 per cent. of the combined freight and passenger earnings, but are nearly 50 per cent. of the passenger earnings alone of the steam railroad properties, while the net income applicable to dividends on capital stock is hardly less than 35 per cent. of the steam railway income. These results are surprising indeed. That 14,000 miles of street-railway track should be able to earn half as much gross on passenger traffic and one-third as much net (for dividends) on combined passenger and freight traffic as is earned on 234,000 miles of steam railroad track—this is certainly a remarkable showing, and one which points to a very reasonable cause for a capitalization per mile of track larger for the street railway than for the steam railway properties."

---

* Paper read at the Albany meeting of the New York State Street Railway Association, September, 1895.

When we have carefully considered the subject of this paper, "Are we laying too many miles of track to reach a few people," the results of a comparison between the steam and street railroads are not so surprising, as there is no doubt if the cities could all be moved within a few miles of one another along the lines of the steam railroads that their passenger receipts would show an immense increase and a corresponding decrease in operating expense.

Even though the steam road charges three cents a mile, and the street railway often gets less than one cent a mile, we find that the receiver's hands and pockets are being filled by the steam roads, because even at three cents per mile enough passengers must be carried to support a lengthy mileage through the unpopulated country.

ECONOMICAL EQUIPMENT AND OPERATION OF POWER HOUSES.*

BY H. S. NEWTON.

I am going to ask the attention of the members to a few of the details connected with the economical equipment and operation of a power house which, ordinarily, do not get further than the engine room, but which might profitably, in a great many cases, be considered in the office.

A modern electric street-railway station, to deserve the name in these advanced days, should embrace in the details of its construction those features which experience has shown to be the best adapted to the service required. These details, I take it, are such as would be included by all engineers in a compound condensing station. A preference has been shown by some engineers for certain additional features, by others for features differing considerably in the means toward the end. It is not my intention to enter into a discussion of the relative merits of different apparatus, or the wisdom of different methods, but I shall confine my remarks to the ways and means which we have considered and have adopted in our power house lately constructed at Syracuse.

The Syracuse Street Railway Company's plant is made up of three double compound engines of the upright, marine type, having cylinder dimensions 16½ x 31 inches, with a 24 inch stroke. These are belted direct to multipolar generators of 300 kilowatt capacity and exhaust each into an independent surface condenser. The condensed steam from the condensers is pumped through an oil filter or separator into a hot well from which the boiler feed pumps convey it through a pipe heater to the boilers. By this arrangement not to exceed ten per cent. of the boiler feed water is taken from the outside water supply, and all difficulty with scale is practically overcome.

The boiler house contains five 90″ tubular boilers, 16 feet long, each made up of 188 four inch tubes. These are fed by a pair of pumps, one acting as a relay to the other. The whole plant has been in operation only a few months, and it has been impossible as yet for us to make an accurate test as to its economy. Our coal and water bills have demonstrated the fact, however, that we are making power at a low rate, and this, with the additional fact that we are having an entire absence of trouble, is all that I can urge as an excuse for this paper.

The feed water is introduced into our boilers through a line of 2½ inch piping connected to duplicate pumps through a pipe heater. We have found two objections to hold against the arrangement as adopted, the correcting of which, I feel, will influence somewhat the economy of the station.

The first of these is the fact that in covering the live steam pipes it was not deemed necessary to cover those carrying the warm water to the boilers. This leads to a difference of some five to ten degrees in the temperature of the water when leaving the heater and when entering the boiler, and is, consequently, a source of some little loss.

The second point is the absence (since remedied) from the feed water line of a check valve beyond the pumps to relieve the check valves at the boilers. This would seem to be of small importance, if not absolutely unnecessary, but we have found it of decided advantage in prolonging the life of the valves and doing away with the rattle occasioned in these valves by the pulsations of the pumps. An air chamber over the pumps is also of prime importance in lending elasticity to the system.

In this connection I wish to call your attention to the importance of an injector on each of the boilers. There seems to be a growing tendency to rely entirely on a relay of pumps, thus allowing the operation of the station to hinge on the efficiency of a piece of apparatus which my experience goes to show has a decided tendency to get out of order.

Concerning the economy of using over and over again for boiler feed the condensed steam from the engine exhausts, a great deal may be said. The surface condenser, the necessary adjunct to this practice, is not a particularly rare piece of apparatus, but I find that a surface condenser which is called upon to perform this one of its functions is decidedly uncommon in street railway practice. In numerous stations it is used to obtain a vacuum, but in very few is the water of condensation utilized. The character of the water around Syracuse made it very desirable that we should utilize the condensed steam if possible, and after what promised to be some very disastrous experience, we have at last succeeded and are running very successfully, as mentioned before, with over ninety per cent. of our feed from this source.

Our immediate result on starting this practice was oil in the boilers, or a mixture of oil and dark brown sediment, which caked over the bottom seams. We removed this and tried again, concluding that it might be shop grease and dirt. Again we had the same result. Examination of the oil filter showed nothing out of order, and consultation with the engine builders evolved nothing new. After endless experimenting, resulting in a leaky boiler or two, and the consumption of a vast amount of chemicals, we have located and remedied the trouble to our entire satisfaction.

The accumulation noticed seems to have been the result of three causes:

(1) The use of too much cylinder oil.

(2) The use of the wrong kind of cylinder oil.

(3) Insufficient filtration of the oil from the feed water before going to the boiler.

The first of these causes was, of course, soon remedied, and the old fashioned notions of our engineers were shocked with the order to use only three drops a minute for each engine.

The second cause we were longer in discovering the remedy for. Various expedients were tried for cutting up the grease in the boilers, such as carbonate of soda, soda ash, tri-sodium phosphate, and lastly kerosene oil. None of these expedients proved effective, however, and it was not until we changed our cylinder oil that we solved the problem. We purchased some oil of purely mineral stock, which has worked so well as to lead me to conclude that it must have been the animal fat in the other oil which was doing the mischief. We are using this oil to-day with remarkably good results, never more than a slight film being apparent in the boilers at the time of the weekly cleaning, and this readily succumbing to the action of a half pail full of soda ash pumped in with the feed water before cooling off.

The third cause of trouble we have recently largely overcome by introducing a number of partitions in our oil filter, by means of which the water is caused to flow alternately over the top of one end under the next, in this way allowing the oil to settle from its water emulsion and be collected in the excelsior filling.

The factor that after all has seemed to be the strongest in the solution of our problem in economy is the choice of fuel. We have done quite a good deal of experimenting in this line with various grades of coal and the results obtained have been such as to lead me to very strong conclusions.

The best coal, and by that I mean the cheapest fuel, we have found to be anthracite buckwheat, costing on board cars at our station $2.25 a gross ton. The dust anthracite I find will sift through the bars. When mixed with an equal amount of soft coal, it works very well, but necessitates the help of an extra man as mixer and is not so economically fired. We use thirteen tons of buckwheat a day, where it was necessary to use seventeen or eighteen of the mixture.

A great deal has been written and a great deal more said about the efficiency of special devices, such as high and low water alarms, automatic damper regulators, etc., in the boiler house. Our experience with them has been most satisfactory. We have found that the less responsibility you place on the man who shovels in your coal, the better off you are in the end; or, in other words, that as compared with human brains, the mechanical device is at a big premium. By making the engineer responsible for the operation of the devices and keeping them in repair, you are insuring yourself a great deal better boiler house economy than you could otherwise expect to obtain.

The vertical marine type of engine has given us thus far very good service. The most serious objection that we can urge to them is that they are noisy. In order that the vertical cross-head guides may not be subjected to too serious wear, we have found it necessary to lower the compression below the point usually employed. The natural consequence is more wear in the cross-head crank bearings and more noise. With more compression we get hot cross-heads and guides, and we consider that we have chosen the lesser of the two evils.

Our engines are provided with piston valves for the high pressure, and gridiron slide valves for the low pressure cylinders. They will govern to within three per cent., or about as well as the Corliss.

I don't think the true importance of good engine government is recognized by street railway men. One is apt to regard a badly governing engine merely as an inconvenience resulting in a lower speed on the cars and dim lights. The additional loss of power on the lines, viz., in the feed wires, trolley wires and rail return, resulting from the decreased voltage at the station is often entirely lost sight of. A few figures on this point might be interesting.

Given a station with generators compounded for a constant potential of 500 volts, with constant speed on the engine, and a system of feeders allowing for an average loss on the line of ten per cent. with full load on the machines. With our engines governing perfectly, ten per cent. is lost in transmission. If they slow down as the load comes on so that the dynamos show only 450 volts with the same watt output, over twelve per cent. of the total energy will be lost in transmission. With 400 volts on the machine, over fifteen per cent. will be lost. Therefore, when we couple these facts with the consideration of the loss of light and decreased efficiency of motors at the lower voltage, it is plain that too much importance cannot be given to the government of prime movers.

In conclusion, I cannot refrain from adding one more voice to the cry against cheap labor in the power house. What help of that kind we do employ, and we are not extravagant I assure you, is used in a subordinate capacity. Our present engineer in charge was employed by me after very clear demonstration that a cheap man was not capable of handling the plant. A condensing station, with the volume of detail which must be always present in its construction, requires brains for its operation; and the man with brains commands good wages. The pressure that is brought to bear on the management for reduction of wages in the power house is often severe, as I can testify, but the moment the concession is made the trouble begins, and a shutting down for repairs on your road becomes a common occurrence.

---

* Paper read before the New York State Railway Association, Albany, September 17, 1895.

THE PROPOSED MAGNETIC UNITS.*—IV.

To the Editor of THE ELECTRICIAN.

SIR: Before the Ipswich discussion—if there is to be a discussion—a few additional lines (not megalines) may be useful in calling attention to a few aspects of the matter which might possibly get overlooked, judging from your "Correspondence" columns of this week. It is easy to exaggerate the oddness of a new name so long as it is unfamiliar, and once upon a time I suppose *ohm* and *megohm* suffered under this disadvantage—in fact, I myself remember that time; but the term ohm now sounds homely enough, although it does not convey its meaning on its surface so clearly as the equivalent term *volt-per-ampere* may, for the sake of illustration, be supposed to do; and this fact, so far from being an objection, is a positive aid towards its free and easy diffusion among operatives and line-testers. Again, the term *volt-ampere* would do instead of *watt*, yet the latter term has come into use; and, similarly, the term joule is simple and handier, although less self-explanatory than volt-sec-ampere.

If compound words, like ampere-turn instead of gauss, and volt-line instead of weber, are enforced for very simple and fundamental quantities, it seems to me that the policy, though plausible for the moment, will be a short-sighted one; because it will then be difficult to proceed further with the formation of compounds, such as weber-per-gauss, which is a unit of permeance, and weber-gauss, which is a unit of energy (and may easily be made a joule). Again, the term *weber-turn* seems to me likely to become in the future nearly as useful as *ampere-turn* has proved itself to be, but it cannot be introduced unless a single name (not much matter what) is affixed to the C.G.S. unit of N or to some multiple of it.

But some of your correspondents appear to hold that no unit names at all are wanted; because if asked hastily for a boiler-pressure the reply "80" is amply expressive. Similarly it might be truly said that when asked in casual conversation for the length of a lease or the age of a man, the reply "99" is completely intelligible; but surely it would be inconvenient not to be able to add the term "years" whenever for precision or completeness it was desirable? And such a term, though meaningless in itself, may be legitimately employed without always having to think what a *year* precisely means; nor would the ordinary man feel grateful if told that he might employ the more expressive phrase *earth-orbital-period* instead. Surely those who doubt the usefulness of names for units (of course introduced in moderation, and after thorough consideration, by collective authority) can hardly remember the vague era before the terms *volt* and *ampere* existed, an era when no one had any instinctive "feel" of what current they were getting out of their Grove or Bunsen cells, which were then mostly the only available large-scale source of electromotive force.

And one more point I must reiterate, though it is admittedly a matter on which a precisionist and a teacher must feel more strongly than practical men and engineers, the reason for adding "pounds per square inch" in a specification of pressure is in truth *not solely* because other countries use kilogrammes per square centimeter; part of the reason is of a much more fundamental character, lying at the basis of the whole idea of absolute measure; nor would it be at all satisfactory silently to assume the C.G.S. system in every case and record only the numerical portion of quantities, although this may be often conveniently done in colloquial haste. Perhaps it has not been clearly noticed by everybody that the unit is just as important a portion of the specification of a concrete quantity as the numerical portion. The height of *anything whatever* is 360 if the appropriate unit be chosen; the figure applies equally as well to the solar prominences, to a fly's probocis and to St. Paul's Cathedral, only the units are different.

Yours, &c., OLIVER J. LODGE.
September 6, 1895.

To the Editor of THE ELECTRICIAN.

SIR: Being so far from the center of civilization, I am afraid the remarks you have asked me to make on the subject of the correspondence on magnetic units in your columns will be late and fall rather flat after the British Association Committee have had their say.

I never can understand the objection to having authorized names for any units at all. Nobody need use them unless they like. Even Mr. Ravenshaw in his own works may, for instance, use the unsystematic units he has accustomed himself to without doing anybody else any harm. As Mr. Esson very sensibly says, "By all means let the scientists invent names for units." The proposal that they be allowed to grow, which has been made by several sensible men, has not in the past led to satisfactory results. We have ounces and grammes and leagues and versts as the result, and, though we are an insular nation, it is to be hoped that the question at issue will be viewed from the international standpoint. Even in the one matter of magnetic force we have names galore growing up. "Lines" and "scots" and gausses" and "thoms" and "hops" and "mags." There is evidently a preponderating preference for a monosyllable, and yet several consider that the names "magnetic line" and "ampere-turn" are short enough for convenience. There are, no doubt, objections to personal names, but as this has been a matter of international agreement, it will probably be best to abide by that decision and continue the system. Questions of jealousy between nations as to the name to be chosen are so amusing it would be a pity to lose these disputes. On the other hand, it is a very good rule to avoid the names of living men, especially when they themselves object.

As regards this question of giving names to units, I think the consensus of opinion is that names should be given to them, and are as a matter of fact being invented by engineers for their own convenience; and so far the appeal for help in deciding this question has been helpfully responded to by engineers, and has led to a valuable contribution to the discussion.

In respect of the much more difficult questions as to the coefficient of induction and of magnetic permeability, hardly any help has been given by engineers, or indeed by any of the correspondents. Mr. Heaviside is in favor of $\mu = \frac{d\,B}{d\,H}$. Most of the correspondents, including Prof. Ewing, to whom Mr. Heaviside appealed, *assume* that no other definition than $\mu = \frac{B}{H}$ is possible. The matter is essentially complicated. The phenomena themselves are very complicated, and there does not seem any prospect of making them simple. Personally, I am rather inclined to $\mu = \frac{d\,B}{d\,H}$, but we really want two different names for the two different quantities, and the only serious question is, to which shall the name "permeability" apply, and what name shall be given to its unit. From the almost universal agreement apparent from the answers it would seem that $\mu = \frac{B}{H}$ has been up to this always called the permeability, and if so some other name should be invented for $\frac{d\,B}{d\,H}$; for it is dreadfully confusing to have the same name for two different quantities, especially to students, whose claims in a matter of the kind are certainly deserving of consideration. Those who find it unnecessary to distinguish between $\frac{B}{H}$ and $\frac{d\,B}{d\,H}$ may stick to one or the other of them, and it is pure dog-in-the-manger for them to object to another name for a quantity that they never use.

As regards the coefficient of self-induction, I think it would be a very great misfortune if the British Association were to set itself up in any degree in opposition to the Chicago International Congress May be the "henry" is not the absolutely best unit, but a confusion of tongues, a new babel of names, would be far worse than any little inconvenience from using the "henry," and when once accredited representatives of a large number of civilized nations have settled upon a term it is most important that all civilized nations should submit to the result and substitute, in science and manufactures at all events, arbitration and agreement for war.

As regards the great 4π question, I entirely agree with Mr. Heaviside in thinking that it is a great misfortune that our units have been founded on the present definitions of a unit pole instead of upon the one he advocates, but I do not at all agree with him in thinking that a change is now possible. The existing inconvenience arising from 4π is not really very serious, and when one considers the enormous difficulty that exists in changing our really terribly inconvenient weights and measures, which costs our country so many years of the life of each child, and so many millions of money in keeping calculators at work who might be employed in something useful, I see no possible prospect of changing our present very seriously inconvenient system of electromagnetic units. There are so many other things better worth doing that I would be very sorry to see my scientific friends engaged in putting their shoulders to this wheel with that expenditure of time and energy that would be required to accomplish anything, especially when the prospect of accomplishing anything is so very minute. Yours, etc.

GEO. FRAS. FITZ GERALD.
Fernbank, Howth, Co. Dublin, Sept. 10, 1895.

THE TELEPHONE SITUATION.

A correspondent writes us, under date of September 23, a very full letter in regard to telephone matters. The letter itself is marked "Not for publication." but since there are so many points raised that are of general interest, we abstract freely from it, but withhold all marks of identification.

The letter is in part as follows, the various points raised being numbered to facilitate reference:

> Is the organization of the Eastern Protective Association completed yet? (1) If so, will you kindly give me the address of its secretary?
>
> The knowledge of the art, as shown in the Berliner patent looks very thin from the present standpoint. Must the development of eighteen years give way to that description of what one does not know about a transmitter? Is there an electrician to-day who can take that specification and make an instrument which will transmit speech, much less receive it? (2) Wherein does his show development beyond the Reis transmitter, descriptions of which were published several years before the Bell telephone was known? (3) If you make a practical one from Berliner's description or in fact a transmitter at all from it, you must make the sensitive contact points of *carbon* (4), instead of *metal* as described. (The word *carbon* is not in the patent.) Do the same from the old descriptions of Reis's instrument and you will have a very efficient transmitter, fully equal or superior to the Blake. I am using one on my switchboard which does not differ in principle from the Reis except that it has carbon contact, and it is a very efficient one.
>
> I hope and trust that all interested will unite, as you advise, and show one solid front against the Bell Company and hit it whenever it shows itself.
>
> The Berliner patent out of the way—what about the call bell? Watson's patent has stood, and will stand nearly four years and a half longer.

---

* From the *Electrician* (London).

The 5th claim seems to cover any kind of a switch which *alternately* connects the line with the ringer magnet, or the 'phone, according to the position of the switch. It seems strange that every maker, so far as I know, clung to the *divided circuit* and switch of some kind, trying only to avoid the *automatic part* of it. Yet the 5th claim does not mention telephone, gravity, automatic or anything of the kind. It *plainly* covers a *divided circuit* and *switch* of any kind. A method for getting around this has been devised as follows: The main circuit is permanently wired through the ringer magnets and 'phone in series, and remains so. No rusty springs; no broken or imperfect contacts; simpler, much cheaper, and very much better than any switch arrangement.

This device has been tried on a circuit 8 miles long with 15 stations besides an extension bell permanently on each line in the central office, working when connected through 17 ringer magnets in circuit, and yet it works nearly as well as a short line with a single station. The equipment in these 15 stations is 7 carbon transmitters, 4 magneto transmitters, and 4 where the receiver is used for both transmitting and receiving, and none have any difficulty in making themselves heard. The system is so much better that I have never known a case where half that number of stations could be well worked by Blake transmitters through Watson call bells (5).

Replying to the above according to bracketed numbers:

(1) The Eastern Protective Association has completed its organization. The address of the secretary is A. F. Stanley, 32 Frankfort street, New York.

(2) (3) (4) The difference consists mainly in this that Reis had not conceived the idea that an uninterrupted current was necessary to the transmission of speech. It is not necessary for the transmission of musical notes, and since that was what Reis was striving for and because by means of an interrupted current greater volume of sound could be obtained, he devised an instrument which was intended to interrupt the circuit at each air vibration. If it failed to interrupt the current, it failed to act as intended, and would certainly be capable under these conditions of transmitting speech. Reis did not understand this, however, and although his instrument probably did at times transmit electrical undulations similar to those necessary for articulate speech, Reis did not discover the reason. The essentials to speech transmission were not discovered until later and were first made known by Bell. He found among other ways that by varying the resistance of the circuit in consonance with sound waves the latter could be reproduced.

Berliner claims to have invented *one way* of varying the resistance of the circuit, viz., by varying the pressure between two electrodes always in contact. His method therefore differed materially from Reis's in that the latter endeavored to *insure* the breaking of contact with each sound wave, while the former endeavored to insure and specified that such break should *not* occur.

That Reis's instrument sometimes failed to work as he wanted it to work, and did something else which he tried to prevent its doing, does not constitute it an anticipation of the utilization of that principle which of all things he was trying to avoid. Nor does the fact that Berliner's early instrument sometimes or frequently did interrupt the current, which of all things it was intended that it should not do, and acted as Reis's instrument was intended to do, constitute a trespass upon Reis's method.

If the two instruments were contemporaneous, Reis and Berliner might both have gotten out valid patents for what they severally claimed and neither instrument would have infringed the other so long as each was used as it was intended to be used.

Our correspondent seems to think that because the contacts in Berliner's instrument are both metal, or at least are both carbon, that it will not act as a transmitter. This is a mistake. It will transmit speech just as it is described in the patent—provided the contact is not broken, as also specified. Were one or both of the electrodes of carbon it would be a far superior instrument and have much wider range, but it was not necessary to use the word "carbon" in the patent to make it operative. In fact the claim is far broader by the omission of the name of any specific substance.

(5) The method suggested for getting around the Watson patent is practicable but will not give so good articulation, as when self-induction is introduced into a telephone circuit it very greatly interferes with the articulation. It acts also like a choking coil, and if there be sufficient present, it will be impossible to speak at all. For this reason, the calling apparatus, which as usually constructed has high self-induction, is best cut out of circuit when the latter is in use for conversation.

We have already expressed ourselves rather fully in regard to the Watson patent as a patent.

GENERAL ELECTRIC'S FINANCING POLICY.

Northwest General Electric—The Scheme, the Companies Financed, the Facts and Figures from the Official Record.

HOW BONDS ARE MANUFACTURED FOR NEW ENGLAND INVESTORS.

CHAPTER XIII.

The Owatonna Electric Co.

The stock and bond deal to which we devote our attention this week is again one of the smaller affairs which went to make up the long record of Mr. Byllesby and the Northwest General Electric Company in their capacity as agents in Mr. C. A. Coffin's grand and comprehensive scheme of electrical financing.

Almost every feature of the plan for manufacturing stocks and bonds and getting rid of them to the credulous Eastern investor, which we have pointed out with so much detail in previous articles, is exhibited in the progress of the Owatonna plant from nothing up to something, then from something back to almost nothing, during which transformations $25,000 to $50,000 of other people's money was transferred to the pockets of the schemers, and an equal or greater amount lost by the legitimate stockholders of the parent manufacturing company through the uncollectible merchandise debts of a lighting plant whose only reason for being was that it was a good thing to bond.

Owatonna is the county seat of Steele County, Minnesota, and had, in 1890, a population of 3,849. It has no advantages over other similar towns in that section. It has no manufacturing enterprises of consequence, but is merely the trading center for the farmers of the county. The houses are thinly scattered over the territory comprised within the town limits, though not so conspicuously so as at Faribault.

In the summer of 1888 Messrs. S. H. and W. S. Pierce, two young men of the section, who had some money and considerable enterprise, and who had heard large stories of great possibilities for making money in central station lighting, decided to embark in the business. Their first venture was at Austin, and the second at Owatonna, where they procured a franchise and a contract for city lighting in the summer of 1890. The original franchise and contract are incorporated herewith:

[COPY].

ORDINANCE NO. 90.

An ordinance establishing an electric light and power plant in the City of Owatonna.

The Common Council of the City of Owatonna, State of Minnesota, do ordain and establish as follows:

Section 1.—In consideration of the benefits that will accrue to the City of Owatonna, of the State of Minnesota, and the inhabitants thereof, it is hereby granted unto Henry Birkett, of the City of Owatonna, State of Minnesota, or his successors or assigns, permission and authority to erect such buildings, machinery and apparatus within the corporate limits of said City of Owatonna as may be necessary for the production and transmission of electricity for the purpose of lighting, heating and furnishing power; and the permission and authority for the period of fifteen years from and after the passage of this ordinance, five years of which first following the date of said franchise shall be exclusive, to place the necessary poles, wires and operating fixtures within the streets, alleys and avenues of said City of Owatonna for the purpose of conducting said electric light, power and heating, said poles and wires to be erected under the direction of the City Council, and said City Council shall have power to direct such changes as it shall deem proper, at the expense of said Henry Birkett, his successors or assigns.

Sec. 2.—The said Henry Birkett hereby agrees not to charge any person or persons more than one cent per hour for each sixteen candle-power lamp by them used, or not more than $5 per month for each arc light of 1,200 candle-power used until 8.30 P. M., or $6 per month until 9 P. M., or $6.50 per month until 10 P. M., or $7.50 per month until 11.30 P. M., and that the said Henry Birkett, his successors or assigns will light the city with as many or as few arc lights as may be desired from time to time for the following prices, to wit:

$7.50 each until 12 o'clock midnight, or $9.50 for all night, each lamp of 1,200 candle power, on the Philadelphia moon schedule; it being understood that no contract for street lighting will be entered into for a less period than five years, and that all halls or public places who may want incandescent lighting shall not be charged over two cents per hour for each sixteen candle power lamp by them used.

Sec. 3.—It is further ordered that in consideration of the benefits hereto accruing to said Henry Birkett, his successors or assigns by this ordinance, the said Henry Birkett shall erect and operate said electric light plant within nine calendar months from the date of the passage of this ordinance.

Sec. 4.—It is further ordered that if said Henry Birkett, his successors or assigns shall at any time after nine months from the date of the passage of this ordinance cease to operate the said electric light plant and it shall not be operated for the period of four months, such inaction and delay shall cause a forfeiture of all rights and privileges acquired under this ordinance, unless otherwise ordered by the said City Council of the City of Owatonna.

Sec. 5.—It is further ordered that nothing in this ordinance shall be construed as forbidding the establishment of private light plants erected and maintained for the purpose of lighting only the property of the owner of said plant.

Sec. 6.—This ordinance shall take effect and be in force from and after its publication.

Passed December 3, 1889.

Attest: E. M. MOREHOUSE,
Mayor.
C. E. LUCE,
City Recorder.

Officially published December 6, 1889.

COPY OF CONTRACT BETWEEN PIERCE BROS. AND THE CITY OF OWATONNA.

This agreement made and entered into this 5th day of August, A. D. 1890, by and between S. H. Pierce and W. S. Pierce, co-partners, doing business as Pierce Bros., successors to the Owatonna Electric Light Company, parties of the first part, and the City of Owatonna, party of the second part, witnesseth:—That for and in consideration of the covenants and agreements on the part of the said party of the second part and their faithful performance, the said parties of the first part hereby covenant and agree to furnish for the said party of the second part ten arc lights of 1,200 normal candle-power for the period of one year from and after September 15, 1890, and to be located as directed by the Common Council of the City of Owatonna, and to be run until midnight according to the Philadelphia moon schedule, including moonlight nights when clouded and dark. The said party of the second part, in consideration of the faithful performance of the foregoing covenants and agreements on the part of the said party of the first part hereby covenants and agrees to pay the said parties of the first part the sum of $7 per month for each light used during the year, payable monthly. It is hereby mutually covenanted and agreed by and between the parties hereto that this contract shall be a waiver of the provisions of Ordinance No. 90, entitled "An ordinance establishing an electric light and power plant in the City of Owatonna," so far as said ordinance relates to the question of the time of contract. In testimony whereof both parties have hereunto signed their names and affixed their seals on the day and year first above written.

S. M. BYRNE,
City Recorde
E. M. MOREHOUSE,
Mayor.

W. S. PIERCE,
(By S. H. PIERCE).

Signed, sealed and delivered in the presence of
I. W. BURCH,
BENJ. E. DARBY.

ARTICLES OF INCORPORATION OF THE OWATONNA ELECTRIC COMPANY.

We, the undersigned, for the purpose of organizing and becoming a body corporate under and by virtue of the laws of the State of Minnesota, in such case made and provided, have adopted and executed the following Articles of Incorporation.

ARTICLE FIRST.

I. The name of this corporation shall be the "Owatonna Electric Company."

II. The general nature of its business shall be (a) to construct, maintain and operate a plant or plants for manufacturing and generating electricity. (b) To deal in, furnish and supply electricity for light, heat and power. (c) To carry on any and all business in anywise appertaining to or connected with the manufacturing and generating, distributing and furnishing of electricity, for light, heat and power purposes, including the transaction of any and all business in which electricity is now or hereafter may be utilized and all matters incidental or necessary to the distribution of electric light, heat and power. (d) To manufacture and repair any and all necessary appliances used in or which may be required or deemed advisable for or in connection with the utilization of electricity or in any wise appertaining thereto or connected therewith. (e) To lease, purchase, hold, sell, convey, mortgage and exchange real or personal property or contracts, and to do any and all other things, and carry on any and all other business operations which may be necessary or advisable in connection with the manufacturing, generating, distributing, selling and furnishing of electricity, or the apparatus and appliances connected therewith as aforesaid.

III The principal place of transacting the business of this corporation shall be the city of Owatonna, in the county of Steele and State of Minnesota.

ARTICLE SECOND.

The time of the commencement of this corporation shall be the fourth day of December, A. D. One Thousand Eight Hundred and Ninety-one (1891); and the period of continuance of said corporation shall be thirty (30) years from said date.

ARTICLE THIRD.

The amount of the capital stock of this corporation shall be Twenty-five Thousand (25,000) Dollars, and the same shall be paid in within fifteen days after the same shall be subscribed for and not later than January 1st, 1892.

ARTICLE FOURTH.

The highest amount of indebtedness or liability to which this corporation shall at any time be subject shall be the sum of Twenty-five Thousand (25,000) Dollars, exclusive of bonded debt, and this corporation may issue and negotiate its bonds at such time in such amounts and secured by mortgage or otherwise as its Board of Directors may deem best, but not to exceed in the aggregate the sum of Fifty Thousand (50,000) Dollars in addition to the above mentioned Twenty-five Thousand (25,000) Dollars of indebtedness or liability.

ARTICLE FIFTH.

The names and places of residence of the persons forming this association for incorporation are as follows: Henry M. Byllesby, St. Paul, Ramsey County, Minn.; George C. Duffie, St. Paul, Ramsey County, Minn.; Wentworth P. Johnson, St. Paul, Ramsey County, Minn.; Benjamin F. Meek, Jr., St. Paul, Ramsey County, Minn.; Howard C. Levis, St. Paul, Ramsey County, Minn.

ARTICLE SIXTH.

I. The government of this corporation and the management of its affairs shall be vested in a Board of five Directors, each of whom shall be a stockholder, and in the following officers, viz., a President, Vice-President, Secretary and Treasurer, and such other officers and agents as the Board of Directors may from time to time appoint.

II. The Directors shall be elected at the annual meeting of the corporation on the first Monday in December in each year.

III. The officers of this corporation shall be elected annually by the Board of Directors at their first meeting each year immediately after the annual meeting of the stockholders.

IV. The President, Vice-President, Secretary and Treasurer shall each be Directors, and their terms of office and the term of office of Directors shall be one year and until their successors are duly elected and qualified.

V. The names of the first Board of Directors of this corporation are: Henry M. Byllesby, George C. Duffie, Wentworth P. Johnson, Benjamin F. Meek, Jr., and Howard C. Levis, and they shall hold office until the first annual meeting in December 1892.

ARTICLE SEVENTH.

The capital stock of this company shall be divided into two hundred and fifty (250) shares of the par value of one hundred (100) dollars each.

In witness whereof we have set our hands and seals this fourth day of December, A. D. 1891.

H. M. BYLLESBY.
GEORGE C. DUFFIE.
W. P. JOHNSON.
B. F. MEEK, JR.
HOWARD C. LEVIS.

Signed and sealed in the presence of
ALICE A. BARRY.
R. V. PRATT.

State of Minnesota, County of Ramsey, ss.

On this fourth day of December, A. D., 1891, before me personally appeared Henry M. Byllesby, George C. Duffie, Wentworth P. Johnson, Benjamin F. Meek, Jr., and Howard C. Levis, to me well known to be the same persons who executed the foregoing instrument, and each for himself acknowledged that he executed the same as his free act and deed for the uses and purposes therein expressed.

[Notarial seal] ROSWELL V. PRATT,
Notary Public, Ramsey County, Minnesota.

Register of Deeds Office, Steele Connty, Minn.

I hereby certify that the within instrument was filed in this office for record on the fifth day of December, A. D. 1891, at 8 o'clock A. M., and was duly recorded in Book "B" of Micl., pages 372 and 373.

G. E. SLOAN, Register of Deeds.

Filed for record in this office December 8th, 1891, at 11 o'clock A. M. F. P. BROWN, Secretary of State.

The magnitude of the operation and its brilliant prospects are manifest. The plant started out with a *sure income* of $70 per month and a one-year contract.

The Pierces were not, however, quite as foolish as their action in starting this plant might denote. They had money, but spent very little of it. They bought their outfit of the Northwest Thomson-Houston Company on long credit, agreeing to pay at least $100 a month. The station was a very good one for a town of the size, but there were not then enough customers for light to make it pay. While Pierce Bros. were trying to educate the people, they were running behind. About a year later their debt to the Northwest General Electric Company was upwards of $7,000, and was increasing.

At length Mr. Byllesby had got his plan in operation, he having come to St. Paul in the early part of 1891. Wherever he had found a railway or lighting plant losing money on a small capital and with careful management, he lost no time in applying the Coffinesque method of making plants pay. In accordance, therefore, with this general plan, the Northwest Company took over the Owatonna station, and Mr. Byllesby proceeded to organize and incorporate the Owatonna Electric Company on December 4, 1891.

The articles of incorporation of this company are herewith placed in evidence. The names of the incorporators and first board of directors are familiar, each and every one being an employé of the Northwest Thomson-Houston Company, working directly under the general orders of C. A. Coffin.

It will be noted that the capitalization was planned at $25,000 stock, $50,000 bonds, and that a further debt of $25,000 was authorized. However, only $25,000 of bonds were actually issued and sold. But the indebtedness of the company was speedily run up above the legal limit, as will be shown by the official records.

Taking up now the record of this Owatonna plant as a commercial enterprise, we find a repetition of the old, old story—plenty of money raised from the sale of bonds, floating debt of the company rapidly increased, apparatus supplied on credit by the Northwest Company, default of interest on notes and bonds—one more of the practical examples of the T.-H. exploiting work added to the "sick list."

During the first year under Mr. Byllesby's direct control some changes were made in the station, some new machinery added. So we will pass over the unfavorable record of results for this year, and merely record the situation at the close of 1893 when the plant had had twelve months' operation without drawbacks of any kind. First let us look at the "Trial Balance."

[COPY.]

OWATONNA ELECTRIC COMPANY.

TRIAL BALANCE FOR SIX MONTHS ENDING JUNE 30, 1893.

Plant account	$61,611.98	
Steam plant	7,550.84	
Electric plant	492 15	
Buildings	6,527.59	
Meters	1,258.36	
Transformers	1,078.24	
Street lines and wire	774.18	
Motors	41 00	
Tools and fixtures	277.73	
Wiring	194.55	
Cash	182.37	
Organization expenses	315.85	
Real estate	50.00	
Accounts receivable	572.37	
Salary of superintendent	225.00	
Wages of engineer and fireman	600.00	
Fuel	1,398.38	
Oil and waste	38.46	
Carbons	70.90	
Boiler compound	56.80	
Lamps	60.30	
Discount	139.05	
Traveling expenses	12.00	
General expense	191.66	
Repairs to electric plant	59.17	
" " steam plant	39.71	
Insurance	274.97	
Taxes	105.00	
Interest	755.37	
		$81,988.98
Credits.		
Capital stock	$25,000.00	
Bonds	25,000.00	
Notes payable (Northwest General Electric Co.)	29,931.66	
Earnings	3,563.05	
Profit and loss	1,182.93	
Surplus (previous year)	341.34	
		$84,988.98

Almost the first thing to occur to the student of the Northwest system is that the debts of the concern were already $4,931.66 more than the law justified. The "plant account, $61,611.98," is no doubt what the concern was carried for as an asset on the books of the Northwest Company.

The earnings and expenses had been as follows:

OWATONNA ELECTRIC COMPANY.

STATEMENT OF EARNINGS AND EXPENSES FOR TWELVE MONTHS ENDING DECEMBER 31, 1893.

Earnings.

	Inc.	Arc.	
January	$382.27	$274.60	
February	382.90	270.00	
March	314.03	264.00	
April	305 95	266.10	
May	271.85	281.50	
June	232.35	287.50	
July	194.75	278.00	
August	234.15	287.50	
September	333.15	282.50	
October	436.15	282.75	
November	586.55	272.75	
December	709.63	277.50	
	$4,383.73	$3,324.70	$7,708.43

Expenses.

Salary officers and clerks	$630.00	
Wages engineers and firemen	1,176.81	
Fuel	2,673.25	
Oil and waste	54.06	
Carbons	135.90	
Boiler compound	95.42	
Lamps	221.25	
Discount	368.18	
Traveling expenses	27.35	
Repairs to electric plant	90.36	
Repairs to steam plant	99.45	
Insurance	274.97	
Taxes	132.48	
General expense	319.45	$6,298.93
Surplus		$1,409.50

This shows an apparent profit of $1,409.50, but no account has been taken of interest, etc.

The fixed charges were as follows:

Interest on $25,000 bonds at 6 per cent	$1,500.00
Interest on $29,931.66 notes at not less than 10 per cent	2,993.16
	$4,493.16
Deduct profits from operations	1,409.50
Deficit	$3,083.66
And to show how far the plant fell short of being a sound enterprise, we must add:	
6 per cent. depreciation on plant account	3,696.71
6 per cent. interest on stock, $25,000	1,500.00
Total deficiency for one year	$8,280.37

The official records show that on December 31, 1894, the situation had not changed materially, but what change there was was in the wrong direction. "Notes payable" had increased to $32.314.31, or $7,314.31 more than the legal limit. Gross earnings were $7,423.21 and operating expenses $6,252.87, leaving $1,170.34, net earnings from operation, or a decrease of $239.16 from the previous year's results.

BOOK REVIEWS.

THE STANDARD DICTIONARY. New York: Funk & Wagnalls Co.

There is but one book that can be said to be more important and necessary to the intelligent man than any other, and that is a dictionary of the language. If a person or family can buy but one book, this is the one which should be bought, and it is important that it should be the best of the kind. When the Century Dictionary made its appearance it was generally felt that the acme of dictionary making had been reached, but there is an old saying that there is nothing so good but that there may be a better, and so it has proved in this case.

Messrs. Funk & Wagnalls have in their Standard Dictionary produced a work which must commend itself to all who give it examination. It is more than a dictionary. It partakes largely of the nature of an encyclopedia, and in this way its utility is much enhanced. To the technical man it commends itself, especially by reason of the care which has been bestowed upon the definition of technical terms. In electricity, for instance, it is a complete electrical dictionary, quite as full, as far as words are concerned, as Houston's Electrical Dictionary, and devoid of the innumerable cross-references which have detracted so largely from the usefulness of the latter.

This part of the work was entrusted to Mr. Ralph W. Pope, and the result has been just what might have been expected at his hands. We have endeavored to find an omission in the electrical vocabulary, but even when we put it to the test of such slang words as "bug" and "nigger," it answers the requirement.

Next to the electrical, the chemical vocabulary seems to be the most complete, and great care has been exercised in its preparation. Here more than anywhere else, perhaps, has the reformed spelling of the American Association been authoritatively represented. The vocabulary of light, heat and optics is nearly, if not quite as full. Thus the student of physical science will find in this one book a complete dictionary of the terms belonging to the various branches underlying the general science of engineering.

The book contains many thousands more words than even the Century Dictionary, and is sold in one and two volume editions at a cost of $12 and $18 respectively, in half Russia. For our own use it is by far the best dictionary thus far published.

OUR discriminating contemporary, *The Electrical Review*, prints the following:

"It is recorded that the first Ural miners were much disgusted with platinum, and did not know what to do with the hard, dirty-looking metal, says a London contemporary. They thought that they had solved the problem of successful utilization when they had made bullets of it for their sporting muskets. The annual platinum consumption of a few years ago of four tons has, of course, increased very considerably with the development of electric lighting."

This may be all right, but the question naturally arises, how did they melt the platinum?

C. A. Coffin on the Shores of White Bear Lake.

To bond, or not to bond: that is the question,
Whether 'tis a surer thing for me
To steal this dummy line outright
And sell it as so much old junk
Or to organize a company and float bonds on it.
To sell: to steal no more; for by a steal
We can gobble up a few thousand good, hard rocks
That several orphans in New England
Are heir to. 'Tis a scheme cleverly to be pushed.
To bond: dead sure thing. To sell: perchance
To lose: ay, I'm no dub.
For we can buy the road with bonds
Then sell these people enough new stuff
To let the T.-H. Co. out.
In this deal no chance will come
That we'll have to wriggle out of legal toils.
Why should we pause?
There's the respect of the law that makes some men poor;
But that don't bother us.
The lawyers wise, slick and shrewd,
They themselves can a quietus put on any kicker
Who would fables bear to investors in the East,
Or tell them that this road can never earn enough to pay interest.
In our prospectus much shall be said
Of the undiscovered country to whose bourne
We will have heavy "induced" travel--
Of Byllesby's bears and our grand pavilin.
'Twill make them mortgage all their property
And fly to Boston to buy at 80 the bonds that cost us 60.
And thus we'll get a heavy haul,
And thus we'll work the "exploiting" game
In other enterprises in the great Northwest.
With this "expansion" of our business
The bond mill in the East will not lose the name of action.

The Science of Circulation.

W. J. Johnston Has A Counterpart at Brownsville.

(From Results, a Chicago Advertising Paper.)

I am business manager of the Brownsville *Daily Weakling*. I am also editor and proprietor of the paper, reporter and book-keeper, but the experiences I am about to relate refer only to my capacity as business manager, so I will simply call myself manager of the business department of this well-known daily.

When I bought this paper, eighteen months ago, it had 380 actual daily circulation. I turned over a horse that I owned for the press and outfit of the paper—no questions asked on either side. We concluded that the ill will of the paper offset the advertising unpaid, and the debts more than wiped out the balance of the assets. The trade was, therefore, easily accomplished. Up to that time I had been selling garden truck about town for a living, and I had always considered my job harder than the editor's. He in turn envied me. So he took my horse and cart and I took his newspaper and launched myself out as a journalist.

The change did not benefit the paper greatly. Nobody seemed to want to pay for it. There was no difficulty in keeping up the 380 circulation so long as I didn't try to collect for it, but the moment I asked pay for the paper the subscription was dropped. I finally concluded that 250 copies were all I could afford to put out in this way, so I let the circulation drop to that point.

This discovery necessitated keeping a pretty stiff upper lip in order to support myself and the paper from the advertising. The claimed circulation when I took the paper was 1,500 copies. With the new blood in it and the new management of course the circulation should increase. Up to this time I had always been pretty honest; in fact it was hard to be otherwise in my old business. But the first thing I learned about the newspaper business was that honesty wasn't expected in this line. Certainly it could never be profitable; so I shortly raised the circulation figures to 2,000, and most of the newspaper directories the next year credited me with that. Thus for the first time the circulation of the *Weakling* was ahead of the Brownsville *Courier*. The *Courier* had for a long time claimed 1,800, and held there. But as soon as I began telling advertisers about my 2,000 circulation, the *Courier* came up to 2,200, and still held ahead of me. This, of course, forced me up to 2,500, and another similar move on their part brought me to 3,000. We had now reached about the limit.

Lately I have reduced my circulation claims a little. I call it 2,875, and say frankly that it has fallen off somewhat in outside towns. This sounds honest, and I find it a great deal better than claiming an even 3,000. The only part that troubles me is the expense of printing 250 copies daily, but I do not see how I can well cut it down. It takes half that number to go to my advertisers, and I must make a little show outside. I think it well to be cautious on this point. When one has the advertising business that I have, he doesn't care to risk it simply to save a few papers. I think that I shall keep the circulation up to where it is.

LATE TELEPHONE NEWS.

THE efforts which a number of independent telephone manufacturers in New York have been making to obtain permission and authority to assume the defence in the suit of the Bell Telephone Company vs. the Bay State Telephone Company of Boston have come to naught. In the proposed assignment of interest in the case the Bay State Company insisted upon such exacting conditions that the New York people found it impossible to accept them, and the deal is now off. It is declared by those in a position to know that the Bay State Company will now permit the suit to go by default, and that the injunction will issue as a matter of course.

COMMUNICATION.

"I."

To the Editor of ELECTRICITY.

DEAR SIR: "An Englishman in America should always try to retain his Englishness—otherwise in a year or two he will be reduced to the level of an average American."

As Mrs. Partington said of the doctrine of total depravity, "this is a good doctrine if it is only lived up to." It is proclaimed by Professor George Forbes in his recent contribution, "Harnessing Niagara," and in this instance at least, it must be conceded that he has lived up to it. The perpendicular personal pronoun occurs in the course of the article no less than one hundred and sixty-five times, by actual count, one unfortunate result of which is that no room is left to so much as mention the name of any other electrician or engineer connected with the design or execution of the work, with the exception of a brief allusion to Nikola Tesla. Forbes *fecit!*

"There are two great mistakes commonly made," says Forbes, "as to Americans. One is that they are original inventors; the other is that they are humorous. Neither of these propositions is true. It is true that if asked to create a knitting-machine or a type-writer, or a reaper, they will put together well-known mechanical devices to accomplish the result. But this is designing, not inventing." "It was therefore perhaps natural," says Forbes, "to have recourse to a European [to wit, Forbes,] to take hold of this great and entirely novel problem." It was also for this reason that "one of the ablest American engineers said in public three years ago that it was impossible to transmit the power of the Falls to Buffalo. some twenty miles, so as to make it pay; whereas *we have now established the fact* [italics ours] that the limit of distance is to be counted by hundreds of miles." This last statement cannot truthfully be said to be lacking either in invention or humor, but then it was not made by an American.

Viewing the Niagara scheme as an entirety, one would imagine that its most characteristically original feature was that of placing the turbines at the bottom of the shafts excavated in solid rock, and causing them to discharge into a tunnel serving as a tail-race, which Professor Forbes admits to have been a thirty-year old conception of an American engineer; and next to that may be placed the two-phase system of alternating current distribution due to the labors of the Montenegron Tesla. Professor Forbes claims to have put these two ideas together to accomplish the result, and lo! we have, in this case, not a mere "design," like that of the type-writer or the knitting-machine or the reaper, but an "invention."

In this article the Professor recounts with great minuteness the various trials and tribulations which beset him in carrying out his great enterprise. "At first, says he, "I declined this invitation [to submit competitive plans] on the grounds that the method of competition is contrary to my professional practice, and also that with so novel a problem I would not accept any man or combination of men to adjudicate upon the project which I might decide upon." Finally, however, he thought better of this, and submitted complete drawings, specifications and estimates of cost. "The Commission," says the Professor, "sat upon these plans"—apparently in the slangy American sense of the term—inasmuch as they "denounced the alternating current." Worse than this, Lord Kelvin, as well as "the highest scientific authority in the States"—whoever he may have been—took the same ground, although the latter, it seems, underwent a subsequent conversion to the true faith, owing, as stated here, to the successful results of the Frankfort-Lauffen installation, but according to another account, to which some reference has recently been made in the columns of ELECTRICITY, by reason of a fat retaining fee proffered by the management of the Cataract Construction Company. "Until *I* went to America, the manufacturers of electrical machinery never had a consulting engineer to reckon with, but dealt directly with the financiers who knew nothing about cost or efficiency of machinery. When they knew that *I* was to advise the Niagara Company, they tried by every means in their power to revert to the old plan. Every game of bluff, bounce and threats was used, but without the least effect." Then again, "I had at times great difficulty in keeping the president and vice-presidents in hand. One of the latter, after he had learned a little about ohms and volts, believed himself capable of instructing *me* as to which tenders I ought to recommend for acceptance." But the Professor gleefully tells us that he had a short and easy method of dealing with such cattle. "On such occasions," he says, "I would write to *my* millionaires, and tell them if they did not do what I told them they would be personally answerable for any disasters that might occur." One crack of the Professor's whip-lash over the heads of his well-broken team of millionaires never failed to make them pull as steady in the harness as the most docile of donkeys; as he succinctly says "this always had the desired effect." Incredible as it may seem, after his experience with the millionaires, he became so emboldened that he even attacked a coterie of six New York Central Wagner-car conductors, who were having a quiet cigar together in one of the smoking-rooms of the train in the early morning hours. We learn that he merely cast one withering gaze over the assemblage, and observed, "I want to smoke, but pray don't disturb yourselves; I am only a passenger." Thus did he, to use his own happy phrase, "retain his Englishness," and put the dismayed car-conductors, "the most insolent men in the country," to instant flight.

Some of the facts brought out in this paper shed light upon certain aspects of the Niagara enterprise which are beginning to excite no inconsiderable amount of discussion in the technical press. Among other things, it is stated that the capital subscribed amounted to $10,000.000, and about half of this has been expended—the first approximate estimate of the actual cost of the works which we remember to have seen. "I got the bids," says the Professor, "for the appliances for the transmission of power to Buffalo. I decided on all this transmission plant, and it is not now put in *only because the Buffalo people* want to get the power for next to nothing."

Is it not possible that the Professor may have stated this proposition wrong end first? How would it accord with the actual facts if we put it in another way, as for example thus:

"The Buffalo people want their power at a price which will justify them in abandoning their steam-plants. Deducting from this price the amount necessary to pay interest and depreciation on a due proportion of the investment of $5,000,000, and of administrative and other necessary expenses, the amount of profit remaining for the Niagara Company is next to nothing!"

We hazard the conjecture that if five years had been allowed to elapse before Professor Forbes had been called upon to render a public account of his doings at Niagara, the numerical repetition of the personal pronoun would have been diminished perhaps 90 per cent., and some portion at least of the credit of designing the electric dynamos would have been conceded to their "disingenuous" manufacturer. We may be mistaken. Time will show.

Yours truly,
AN AVERAGE AMERICAN.

GENERAL NEWS.

What is Going on in the Electrical World.

Le Sueur, Minn.—This city has voted to issue $20,000 bonds for water and electric light plants.

Delevan, Wis.—The village board has decided to contract with the Electric Light Company for the lighting of the streets.

San Jose, Cal.—At a meeting of the board of trade a resolution was adopted favoring city ownership of the lighting plant.

Cromwell, Conn.—The selectmen have granted the Middletown Electric Railway Company the privilege of a trolley system in this town.

Wellsboro, Pa.—The Wellsboro borough council have resolved to contract for 20 arc street lights of 2,000 candle-power at an estimated cost of $2,000.

Oshkosh, Wis.—The Central Wisconsin Electric Company has negotiated a loan of $300,000 to enable it to complete the local and interurban electric railway systems.

Homestead, Pa.—A fly-wheel at the electric light works here burst on the 4th inst., killing John Bowman, the engineer, and doing considerable damage to the building.

Meridian, Miss.—The city boards have granted a franchise to W. R. Hall, of Chattanooga, and associates to construct and operate an electric street railway in this city.

Holyoke, Mass.—There is a fair prospect of an electric railway being built to South Hadley from Holyoke early next year. The course will be surveyed and laid out at once.

Millbury, Mass.—It is stated that several concerns in town who need a small amount of power will put in electric motors as soon as they can be provided with electricity in the daytime.

Hicksville, L. I., N. Y.—The Long Island Electric Company intends to establish a plant at Hicksville and supply the villages of Jericho, Syosset, Central Park, Farmingdale and Westbury.

Paris, Tex.—The streets have been graded for the new electric car line. The line to West Paris will be constructed first and after that is completed the reconstruction of the old line will begin.

Pittsburg, Pa.—The Second Avenue Traction Company has completed the laying of its tracks from Brinton to Wilmerding, and cars are now running direct between the latter place and Pittsburg.

Johnstown, N. Y.—George A. Streeter, of Johnstown, and parties from New York will soon erect an electric plant to furnish this city and its business places and private residences with light and power.

Burlington, Vt.—The Sunset Electric Company have asked permission to build and operate a railway in certain streets of this city, and state that they are willing to bid for the franchise if put up at auction.

Bay Shore, L. I., N. Y.—George B. Studley and Archibald J. Martin have applied to the town board for a franchise to run a trolley line from Brentwood to Bay Shore, thence to Oakdale and west to Babylon.

Bradford, Vt.—A preliminary organization has been effected in Bradford for the purpose of erecting an electric light and heating plant and carrying on the business of an electric lighting and heating company.

Los Angeles, Cal.—The Los Angeles and Pasadena Electric Railway Company proposes to extend its line from Pasadena to Altadena and has applied to the board of supervisors to advertise a franchise of the route for sale.

Saginaw, Mich.—At a meeting of the township board of Bridgeport, a 30-year franchise was granted to the Saginaw Street Railway Company to run a line along the Genesee plank road from the city limits to Bridgeport.

Urbana, O.—W. H. Hanford & Co. have accepted the franchise for an electric railway granted them by the council. This is the line intended to connect this city and Springfield. The entire right of way has been secured.

Menasha, Wis.—The Citizens' Electric Light and Power Company, having declined to accept the franchise granted by the council, that body has decided to advertise for bids for lighting the city with between fifty and sixty arc lights.

Omaha, Neb.—The South Omaha Electric Light, Heat and Power Company's plant and privileges have been purchased by the South Omaha Water Works Company, of which John A. McShane is president and B. S. Scannell is secretary.

Augusta, Ga.—The Augusta Street Rilway Company is in the hands of a receiver. The action is a friendly one preparatory to reorganizing the company and putting the railway on a dividend-paying basis. D. B. Dyer is the receiver.

Seattle, Wash.—Sealed proposals will be received by George F. Meacham, secretary of the board of public works, at the office of the board, until October 31, for furnishing street lights to the city of Seattle according to plans and specifications now on file.

Philadelphia.—According to "The Press," the street car companies' receipts from "trolley parties" in this city during the past summer amounted to $70,000. Allowing 10 cents for each passenger, this shows that 700,000 persons indulged in that kind of enjoyment.

Alton, Ill.—The town board of Upper Alton have accepted the proposition of George C. Morgan, of Chicago, to build a complete water works and electric light plant for the sum of $53,432. The contract, as accepted, calls for thirty-five arc lights.

Kingston, N. Y.—If right of way is secured, the Port Jervis, Monticello and New York Railway Company will extend its line to Kingston. This would give the people of the Rondout Valley a trolley service between Port Jervis and Kingston by way of Ellenville.

Chicago.—Dr. J. W. Wass, of West Pullman, says he has discovered a cure for diphtheria which far exceeds anti-toxine in efficacy. Dr. Wass's remedy is electricity, which is applied directly to the throat. A conference of physicians will be held to pass on the alleged cure.

Toledo, O.—Work has been commenced on the right of way for a new electric line from Toledo through Sylvania, Metamora, Lyons and Fayette to Pioneer. M. I. Wilcox, James M. Ashley, Jr., and other Toledo capitalists are interested. The road will be pushed rapidly.

Bay City, Mich.—The Consolidated Street Railway Company of this city has made contracts with both the Rapid Transit and Interurban Company, which propose to build lines between Saginaw and Bay City, and the new companies will reach the business center over its lines.

Middletown, Md.—Work on the permanent survey of the Frederick and Middletown Electric Railway has begun and the grading of the road will be in progress by the latter part of this month. A call has been issued for 20 per cent. of the capital stock, payable on or before October 15.

St. Louis.—All the local street railway lines, with the exception of the Suburban, will send delegates to the Convention of the American Street Railway Association to be held in Montreal October 15-17. The delegates will make a strong effort to have the convention brought to St. Louis in 1896.

Ellicott City, Md.—The preliminary work on the station and other necessary structures for the Ellicott end of the Edmondson Avenue, Catonsville and Ellicott City Electric Railway has been commenced. A force of hands is now at work grading and placing the foundations for the railroad buildings.

Milford, Mass.—The Electric Storage Battery Company of Philadelphia is reported to have purchased the three shops and all the patents, machinery and cars of the Hopedale Electric Company, and will make Milford their New England station. W. L. Stevens has been engaged as superintendent of the Milford plant.

Brooklyn, N. Y.—The Nassau Electric Railroad Company has been improving its plant at the power house at a cost of $50,000. In addition to this, it is stated that General Manager J. J. Coleman has ordered 200 open cars from the J. G. Brill Company of Philadelphia, for use next summer on the new Manhattan Beach road.

Elyria, O.—The city council has granted a franchise to James A. Mauldin, representing Cleveland capitalists, to construct an electric railway through the city, beginning at the southern limit. It will be extended to Lorain and North Amherst, making the second line to connect Elyria and Lorain. Work on the line is to begin at once.

Sherman, N. Y.—Active steps are being taken in an electric street railway project which is practically an extension of the recently proposed electric road from Barcelona, on Lake Erie, via the Gulf to the Chautauqua Assembly Grounds. A. B. and W. L. Minton of Westfield, F. A. Ellis, J. L. Thayer and T. S. Marion of Sherman, are interested.

Benton Harbor, Mich.—Paw Paw Lake, situated one mile from Watervleit and twelve miles north of Benton Harbor, which is so fast becoming a beautiful summer resort, will soon be connected with this city by an electric railway, which was decided upon only a few days ago by several capitalists who are interested. A survey of the new route has just been completed.

Logansport, Ind.—A new electric road is to be constructed connecting this city with Rochester, Fulton County, and Burlington, Carroll County. The road will be about thirty-five miles long. J. T. McNary, formerly manager of the Logansport Street Railroad, is at the back of the new road and has interested several Eastern capitalists. A company will be organized in a short time.

Paxton, Ill.—Articles of incorporation have been filed by the Danville and Paxton Electric Railway Company, and capitalists are being interested in the plans of the company. The cost of building the forty-three miles of proposed road is estimated at $9,000 a mile or a total of $387,000. At a recent meeting here C. Bogardus, W. T. Patton and L. Corbly were appointed a committee to secure twelve miles right of way.

San Francisco.—The "Call" states that the proposition for municipal ownership of water works, gas works and electric lighting plants is steadily growing in favor in this city, and petitions are being circulated having this purpose in view.—The opposition to the use of electric cars on the steep grades of the Piedmont Hills has apparently ceased and a contract has just been signed by which that branch of the system will at once be changed from a cable to an electric road. The change will be experimental so far as using the cable is concerned. The cable will be kept in repair and will probably be operated when it is necessary to carry more passengers than the electric service can accommodate.

BUSINESS HINTS.

Public Buildings, Theaters, Residences, &c., Proposed or in Course of Construction.

[The following summary is prepared weekly for ELECTRICITY for the information of advertisers and readers who are dealers in apparatus and articles required in the electrical equipment of public and private buildings.]

Boston, Mass.—J. Pickering Putnam, architect, has prepared plans for a hotel to be erected on Commonwealth ave., beyond the Three Roads; Charles Francis Adams is one of the trustees.

Brooklyn, N. Y.—McLaughlin Bros. will erect an eight-story printing house on the north side of South 11th st., east of Wythe ave.; to cost $60,000 .. The plans and specifications of the new building for the Brooklyn Institute of Arts and Sciences have been approved by Building Inspector Wesley C. Busch; the structure will be located on Eastern Parkway; Architects McKim, Mead & White, 160 5th ave. New York City....The Morris Building Company will erect a three story brick house on east side of Clinton ave., south of Willoughby, to cost $30,000.

Buffalo, N. Y.—Herbert J. Myer, proprietor of the American Theater Roof Garden, New York City, has been in Buffalo, looking over the situation and making arrangements for the erection of a Music Hall....Architect George J. Metzger has prepared designs for a six story brick building to be built on west side of Pearl st., between Eagle and Court sts., for Philip Becker & Co., grocers.

Dunbar, Pa.—There are indications that there will soon be erected a large business block in Dunbar, at a cost of $50,000 or $60,000, consisting of a large opera house and a hotel on a new and improved plan.

New York City.—Ground will be broken for a new theater, southeast cor. of Lexington ave. and 42d st., next spring, to be erected by the Goelet Estate, and when completed will be managed by Frank Murtha....The Harlem Wheelmen have appointed a committee to procure a site on the west side of the city for a club house to be erected after plans prepared by Robert D. Morrison....The Bohemian Gymnastic Association, "Sokel," 533 E. 5th st., will erect a four story brick clubhouse at 420-424 E. 71st st., to cost $55,000; Architect Julius Franke, 287 4th ave....John T. Williams, purchaser of the Lawrence Estate property, Broadway and White st., will remove the present buildings and erect a modern fire-proof and commercial building on the site.... David L. Newborg has sold J. C. Lyons, 81 E. 125th st., property at 491-493 Broadway and 446 Broome st., fronting on Broadway; the old buildings on the site will be torn down on February 1 and a modern 12 story business building erected on the site....Blake & Nally will erect 4 five story flats on south side of 88th st., west of Amsterdam ave., from plans prepared by Architects Webster & Thompson, 215 W. 125th st.; specifications include steam heating appliances, electric bells, etc. .. James B. Brown, 124 W. 90th st., will erect two five story brick flats on north side of 102d st., west of Amsterdam ave.; Architect, C. Steinmetz.... Robert Ferguson, 743 8th ave, and Wm. Cummings, 405 McDonough st., Brooklyn, will erect a four story and basement store and flat building on east side of Amsterdam ave., cor. 108th st.; Architect George F. Pelham, 503 5th ave... An apartment house is to be built northwest cor. Madison ave. and 89th st., by Nicholas Cotter, builder....Charles A. Rich, 265 Broadway, will build a four story dwelling on north side of 91st st., east of West End ave.; Architects Lamb & Rich, 265 Broadway.....Mrs. Margaret F. Mace (Maggie Mitchell) has purchased two lots southwest cor. of West End ave. and 102d st., and will build an eight story fireproof apartment house from plans by Wm. H. Day, 1 Madison ave .. T. C. Smith has purchased the northwest cor. of Madison ave and 108th st., and will build four five story flats with stores, 100 x 87....Nicholas Cotter will erect three five story apartment houses, southeast cor. of Manhattan ave. and 103d st., on site which was recently purchased from Adler & Herman.

Philadelphia, Pa.—A six story office building is to be erected by Contractor S. B. Riley at the northwest cor. 4th and Merchant sts....Alterations are to be made to Handel and Haydn Hall, at 8th and Spring Garden sts., by Contractor Matthew Schmid; an elevator is to be installed and the property otherwise improved.

Providence, R. I.—A modern residence will be erected here for President Andrews of Brown University.

Saratoga, N. Y.—Ground has been broken at 1 Marion place for a new residence for Addison E. Curtis, of the Citizens' Bank.

St. Louis, Mo.—Architects Kirchner & Kirchner are preparing plans for the erection of a building which will be a swimming tank, ice skating rink and bicycle school; a stock company is being organized with a capital of $200,000 to carry out the scheme.

INCORPORATIONS.

The Enterprise Company, Portland, Ore.—to buy patent rights or inventions, to manufacture machines for affixing stamps, to acquire sailing craft, electric, cable, and steam railroads and novelties in general. Capital stock, $12,000; Incorporators: Stephen W. Aldrich, Henry C. Allen and John B. David.

The Metropolitan Electrical Development Company, Jersey City, N. J.—to manufacture, purchase, sell, hire, own, let or maintain motor engines, electric or otherwise, etc. Capital stock, $1,000,000. Promoters: John R. Dos Passos, Thomas D. Jordan, Chas. J. Canda, Wm. L. Moore, New York City; Conrad N. Jordan, Brooklyn, N. Y.

The Wilson-Bates Electric Company, New York City—to make and sell electrical or magnetic machinery, devices, etc. Capital stock, $1,500. Promoters: W. C. Wilson, G. B. Bates, H. G. Issertel, New York City.

The Sunset Electric Company, Swanton, Vt.—to manufacture, sell and furnish heat, power and artificial light. Capital stock, $15,000. Promoters: E. W. Jewett, A. J. Ferris, J. B. Jewett, Swanton.

The Central Construction Company, Oshkosh, Wis.—to construct electric railway lines. Capital stock, $300,000 Incorporators: E. E. Stevens, W. F. Gruenwald and N. A. Greenlaw.

The Munson Electric Conduit Company, Davenport, Ia.—to build and equip electric railways and handle all sorts of electrical supplies. Capital stock, $10,000,000. Incorporators: John H. Munson, James E. Merritt and William F. Roberts.

The McBair Electric Heating Company—to manufacture electric heating apparatus in Middletown, N. Y. Capital stock, $2.000. Directors: Henry C. McBair, Thomas E. Hayes and Harry M. Hayes of Middletown.

The Horton Obtunding Company, Cleveland, Ohio—to make an electric apparatus for dulling the sensibilities so as to make surgical operations painless. Capital stock, $30,000. Incorporators: W. P. Horton, M. C. Horton, J. J Shipherd, E. W. Badder and M. H. Solloway.

The Bethel Electric Lighting and Power Company, Bethel, Vt., has organized with a capital stock of $15,000. Mr. Stafford, president; W. H. Creamer, treasurer and general manager.

The Bordentown Electric Light and Motor Company, Bordentown, N. J.—to construct, maintain and operate works for supplying electricity for electric light, heat and power. Capital stock, $50,000. Promoters: James S. Gilbert, Wm. C. Steele, Geo. B. Gilbert, Bordentown, N. J.; Thos. Bennett, Amos G. Little, Philadelphia, Pa.

The Kansas City and Leavenworth Railway Company, Kansas City, Kan.—to maintain a double track standard gauge railroad, either steam or electric. Capital stock, $500,000. Promoters: W. A. Bunker, Arthur Johnson, H. A. Keefer, C. F. Hutchings, Kansas City; James Stone, Jr., Leavenworth.

The Clearfield Light, Heat and Power Company, Clearfield, Pa.—to supply light, heat and power by means of electricity to the public in Clearfield. Capital stock, $5,000. Promoters: H. A. Kratzer, J. F. Powell, G. S. Hughes, Clearfield.

The Canca Valley Development Company, San Francisco, Cal.—to supply water, gas and electricity, etc. Capital stock, $1,000,000. Promoters: Carl W. Elfving, Victor F. Seawell, Arthur Elliott, Bion S. Gregory, Adolfa Canal, San Francisco; M. Hubbard, Los Angeles.

The Victor Electric Company, Chicago—to manufacture electrical appliances. Capital stock, $2,400. Incorporators: C. F. Samms, J. B. Wants and E. P. Vickers.

The Niagara Falls Street Railway Company—to construct a street surface railroad in the city of Niagara Falls. Capital stock, $50,000. Directors: Arthur C. Deniston, Charles S. Hinchman, George L. Estabrook, Jr., Joseph S. Clark, Robert J. Byron, of Philadelphia, Pa.; James S. Simmons, E. H. Stewart, Walter H. P. Horne and Spencer J. Lawrence, of Niagara Falls.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 8, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

547,457. Trolley-Track. Antony Shumacher, Millington, N. J. Filed March 21, 1895.

ELECTRIC LIGHTS AND APPLIANCES.

547,536. Electric Car-Lighting Apparatus. William Biddle, Brooklyn, N. Y. Filed Dec. 24, 1894.

547,537. Electric Car-Lighting. William Biddle and Harry E. Dey, Brooklyn, N. Y., assignors to said Biddle. Filed Jan. 9, 1895.

547,659. Electric-Arc Lamp. Harold E. Bradley, Pawtucket, R. I. Filed July 1, 1895.

547,753. Cut-Out for Arc Lamps. Daniel Higham, Boston, Mass., assignor to the Higham Electric Company, Portland, Me. Filed June 27, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

547,460. Telephone System. Frederic D. Shepard, Milwaukee, Wis., assignor to Frederick S. Ilsley and James Sawyer, same place. Filed Feb. 18, 1895.

547,613. Telephone Switch. Willard M. Miner, Plainfield, N. J. Filed June 4, 1895.

547,755. Automatic Telephone System. George K. Hutchins, Baltimore, Md. Filed May 6, 1893.

MISCELLANEOUS.

547,240. Electrical Safety Apparatus for Railways. Lewis W. Briggs, Chicago, Ill., assignor of one-half to William F. Cody, North Platte, Neb., and Nathan Salsbury, New York, N. Y. Filed Aug. 24, 1893.

547,358. Electric Synchronizer for Clocks. Henry S. Prentiss, Elizabeth, N. J., assignor to the Prentiss Clock Improvement Company, New York, N. Y., and Jersey City, N. J. Filed Aug. 10, 1892.

547,441. Electric Bicycle. Hosea W. Libbey, Boston, Mass. Filed Oct. 9, 1894.

547,476. Motor-Truck. John A. Brill and Walter S. Adams, Philadelphia, Pa. Filed Jan. 3, 1894.

547,568. Electric Key-Action for Pipe-Organs. Edwin S. Votey, William B. Fleming and William D. Wood, Detroit, Mich., assignors to the Farrand & Votey Organ Company, same place. Filed Jan. 21, 1895.

547,591. Switch and Fuse-Box. Joseph B. Smith, Manchester, N. H. Filed April 12, 1895.

547,660. Insulator-Pin and Insulator. Charles F. Carroll, Manistee, Mich., assignor of one-half to Thomas Scott, same place. Filed June 6, 1895.

547,683. Phase Modification. Henry A. Rowland, Baltimore, Md. Filed May 19, 1894.

547,714. Time-Controlled Electric Heater. Levitt E. Custer, Dayton, Ohio. Filed Dec. 22, 1894.

THE "A-B" ARC LAMP.

Early in May there was noticed at some length in this journal an account of the formation of the Adams-Bagnall Electric Company, of Cleveland, O. This company was organized by a number of gentlemen who long held important positions in the engineering and business departments of one of the leading electrical manufacturing companies and who have been prominently identified with many departments of electrical work. Since the formal announcement of the organization of the company nothing has been heard of its operations. It has not, however, been idle, but has been busily at work completing the designs and perfecting the details of the special apparatus it will place on the market. The preliminary work is now completed and the company makes its bow in introducing the "A-B" Arc Lamp to the trade.

The accompanying illustration makes it plain that in construction of arc lamps many new ideas have been evolved by the designers and inventors of the "A-B" Lamp.

The term "arc lamp" has always seemed to carry with it an idea of ungainliness—a device having no form or shape and strung out over 45 to 50 inches of space, divided up into sections of chimneys, rods, globes and sheet-iron drums—for reasons known only to the manufacturer. The trade has always looked upon an arc lamp as a necessary evil. The demand for something better is universal.

The "A-B" Arc Lamp is only 32 inches long over all and burns from 14 to 18 hours. It is a single carbon lamp with only one side rod, which causes only one shadow to be thrown. This shadow can be taken care of against the pole or building, leaving the light intended for the street entirely unobstructed.

A valuable feature about the operation of the lamp is in the cutout. It is well known that there are some standard lamps on the market which operate and cutout perfectly at any number of amperes provided that the lamp has previously been adjusted for a certain number of amperes. The "A-B" Lamp will, however, operate and cutout perfectly at any number of amperes from 5 to 10, without any adjusting whatever. The accomplishment of this feat renders it feasible and easy for the station manager to run either 1,200 or 2,000 candle power lamps as suits his convenience, with a change of nothing except the ampere output of his dynamo. Since the invention of the cutout itself, some twenty years ago, no step in the development of the arc lamp has been of greater importance.

Second in importance only to the above mentioned feature is the fact that the series lamp of the "A-B" type can be changed instantly into a constant potential lamp and that again into an alternating current lamp simply by an exchange of spools. All of the working parts of each lamp are mounted on one frame, which frame is attached to the lamp casing by a single bolt and nut. By loosening this nut the working parts of the lamp are removed and those of another can be readily substituted. One style of lamp only need be carried in stock by the station manager and with the addition of several kinds of spools he will be prepared to furnish a lamp for any kind of circuit.

The "A-B" Lamp will be furnished in any finish desired—black japan, yellow brass, XVIIth century brass, oxidized brass, oxidized copper, oxidized silver and aluminum. This provides an arc lamp good enough to hang in a parlor—it being possible to match any style gas fixture or decoration. The aluminum lamp complete weighs only nineteen pounds. The casing being of cast iron provides a solid back ground for ornamentation, giving the lamp a dignified, substantial appearance, quite different from the brass and sheet-iron spun work usually adopted where ornamentation on arc lamps has been attempted heretofore.

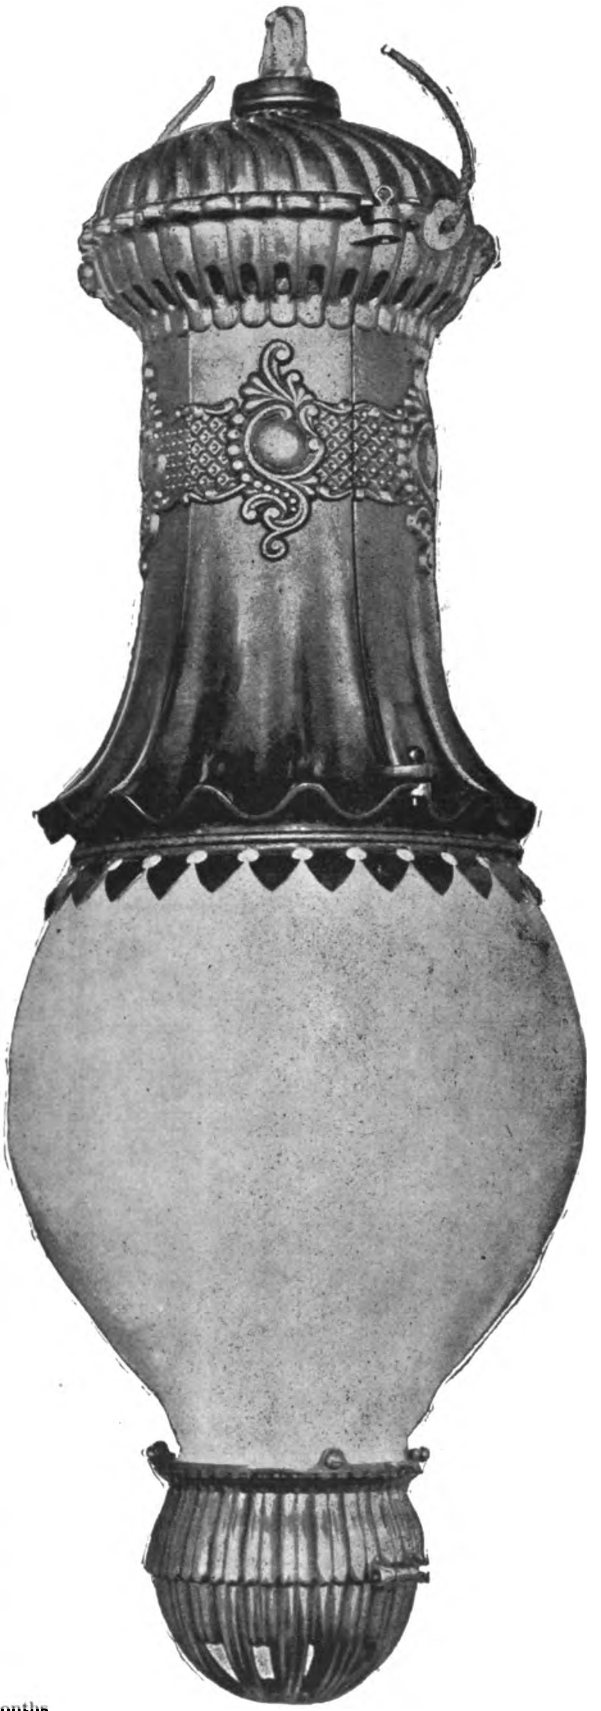
The "A-B" Lamp is the direct result of several months of close study and application by the engineering corps of the Adams-Bagnall Company headed by T. E. Adams, the well known inventor of the Brush-Adams lamp. The results obtained point to a lamp which will certainly take its stand at once among the leading lamps of the day, which assuredly means success for the new company.

The officers of the Adams-Bagnall Electric Company are as follows: Charles G. Hickox, president; Geo. W. Howe, vice-president and treasurer; L. H. Rogers, manager; S. E. Cox, secretary; C. W. Phipps, superintendent.

The Okonite Company, Limited, make a specialty of feeder wires for street railway use. They are tough and tenacious, and are not affected by extreme changes in temperature. Okonite has made an enviable record both in this country and abroad, and is deservedly the most popular insulation known to the electrical fraternity. It is strictly high-grade and "never disappoints."

A reorganization of the W. C. Leffel Company, water wheel manufacturers, Springfield, O., has been effected by the election of the following officers:

President, John J. Hoppes; vice-president, Wm. Conklin; general manager, Fuller Trump; treasurer, Paul A. Staley; secretary, Percy Norton.



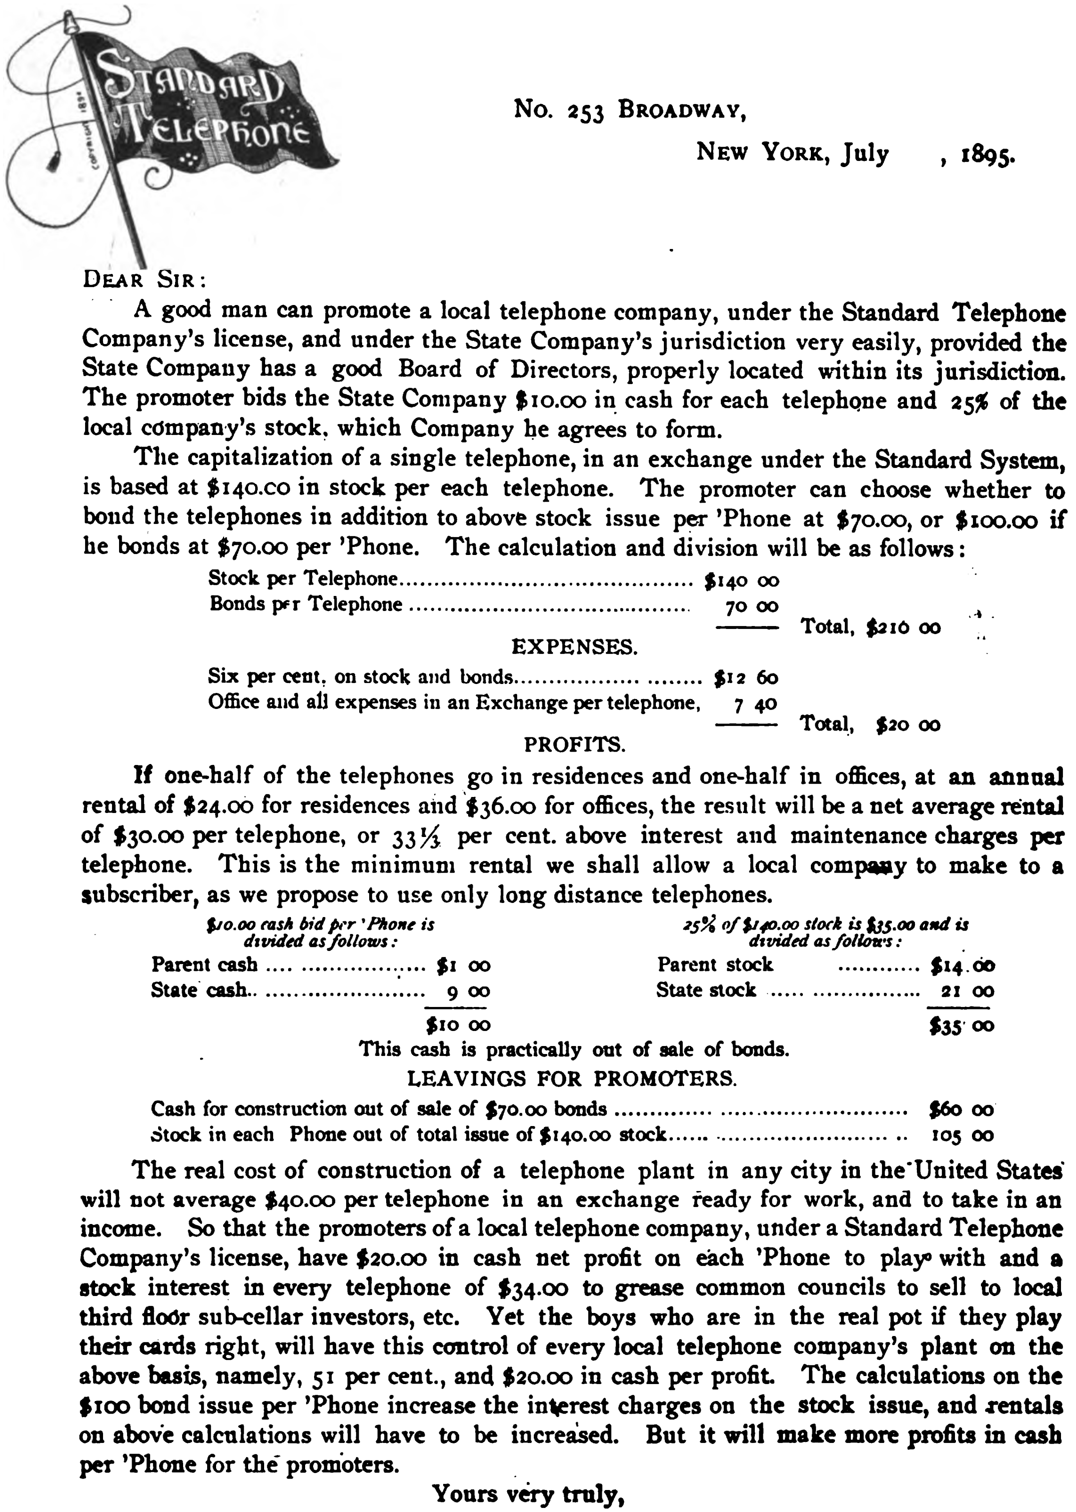
THE "A-B" ARC LAMP.

The new company will be styled The Trump Manufacturing Company, with a capital stock of $100,000. The same line of goods will be manufactured as heretofore and especial attention will be given to the manufacture of Fuller Trump's new water wheel.

THE TELEPHONE WORLD.

How to Promote Telephone Companies.

A Fac-simile of the Standard Telephone Company's Circular Letter of Instructions to "The Boys who are in the Pot."



STANDARD TELEPHONE
COPYRIGHT 1894

No. 253 Broadway,
New York, July , 1895.

Dear Sir:

A good man can promote a local telephone company, under the Standard Telephone Company's license, and under the State Company's jurisdiction very easily, provided the State Company has a good Board of Directors, properly located within its jurisdiction. The promoter bids the State Company $10.00 in cash for each telephone and 25% of the local company's stock, which Company he agrees to form.

The capitalization of a single telephone, in an exchange under the Standard System, is based at $140.00 in stock per each telephone. The promoter can choose whether to bond the telephones in addition to above stock issue per 'Phone at $70.00, or $100.00 if he bonds at $70.00 per 'Phone. The calculation and division will be as follows:

Stock per Telephone	$140 00	
Bonds per Telephone	70 00	
		Total, $210 00

EXPENSES.

Six per cent. on stock and bonds	$12 60	
Office and all expenses in an Exchange per telephone,	7 40	
		Total, $20 00

PROFITS.

If one-half of the telephones go in residences and one-half in offices, at an annual rental of $24.00 for residences and $36.00 for offices, the result will be a net average rental of $30.00 per telephone, or 33⅓ per cent. above interest and maintenance charges per telephone. This is the minimum rental we shall allow a local company to make to a subscriber, as we propose to use only long distance telephones.

$10.00 cash bid per 'Phone is divided as follows:		*25% of $140.00 stock is $35.00 and is divided as follows:*	
Parent cash	$1 00	Parent stock	$14.00
State cash	9 00	State stock	21 00
	$10 00		$35 00

This cash is practically out of sale of bonds.

LEAVINGS FOR PROMOTERS.

Cash for construction out of sale of $70.00 bonds	$60 00
Stock in each Phone out of total issue of $140.00 stock	105 00

The real cost of construction of a telephone plant in any city in the United States will not average $40.00 per telephone in an exchange ready for work, and to take in an income. So that the promoters of a local telephone company, under a Standard Telephone Company's license, have $20.00 in cash net profit on each 'Phone to play with and a stock interest in every telephone of $34.00 to grease common councils to sell to local third floor sub-cellar investors, etc. Yet the boys who are in the real pot if they play their cards right, will have this control of every local telephone company's plant on the above basis, namely, 51 per cent., and $20.00 in cash per profit. The calculations on the $100 bond issue per 'Phone increase the interest charges on the stock issue, and rentals on above calculations will have to be increased. But it will make more profits in cash per 'Phone for the promoters.

Yours very truly,

The Fittest Will Survive.

Once in a while, and then more by accident than design, the lay press stumbles on to a truth touching the commercial side of the electrical trade. A case in point is a recent article in the *Chicago Record* on the telephone situation, as follows:

"It is to be feared that a good many people will have their fingers burned before the telephone business, which is just now about the most risky branch of industry that anyone can handle, comes down to a sound and healthy basis. The country is full of 'promoters,' most of whom have fixed such low rates for telephone service that the public has been led to think that the business is all income and no expense. Persons who are figuring with the companies are advised to scan closely the telephone contracts presented to them to sign. Some of these contracts bind the parties for several years to take and use a service which must of necessity be inferior at the price named. The average promoter always has plenty of loopholes through which he can retire in his own good time. The truth is that the public has been suffering so long from high telephone rates that now, when good service at moderate rates is in sight, they have rushed to the other extreme and embraced the idea that telephones can be had for next to nothing. This idea has been encouraged and disseminated by interested persons, who have lost no time in turning it to their own ends. New telephone companies have been started which could not possibly do a permanent business at the rates they promise, and whose only object has been the sale of stock as soon as the appearance of active demand for instruments has been worked up. Other companies have put cheap telephones on the market only to find that they have left no margin of profit, and the loss has come upon the manufacturer, whose bills have been left unpaid. It is probable that by far the majority of small telephone companies will gradually die off, either from infringement suits or because they are built on sand. The fittest of the non-infringing will probably survive."

A Talk Meter Needed.

J. R. Malloy, manager of the Central Pennsylvania Telephone Co., Williamsport, Pa., is of the opinion that "acrying need in the telephone business is a talk-meter—that is, some sort of an automatic arrangement by which language can be measured off by the yard. What is required is a regular 'gas' meter, with a stopcock for profanity, old jokes, and endearing names for the telephone girls. I think an arrangement of this sort would be more valuable than an automatic device for making the connections. Many a wordy tale would be cut short, many a delicious but unprofitable confab nipped in the bud. A comfortable share of the telephone investment would go to the man who would invent a talk-meter."

One Way of Stifling Oppositi

The Citizens' Telephone Company of Pen

AMERICAN ELECTRICAL CASES.

A CURRENT SERIES.

Edited by WM. W. MORRILL. Published by MATTHEW BENDER, Albany, N. Y.

Vols. 1, 2 and 3 of the series have been published and have met with a reception that fully justifies the publisher in permanently continuing the series, the scope of which is to broadly cover all electrical cases coming before the courts in all sections of the country.

In Vol. 2 there were 130 cases, and of these 69 pertain to the duties and liabilities of telegraph companies as carriers of news. In Vol. 3 the telegraph cases number 42.

The subject of Interference of Electrical Currents, usually made prominent in actions brought by telephone companies whose weaker currents are unfavorably affected by the powerful currents used by light and power companies, is represented by one case in Vol. 1, two cases in Vol. 2, and ten cases in Vol. 3.

The RIGHTS OF ABUTTING OWNERS, as affected by the maintenance of electrical apperatus in highways, are considered in six cases in Vol. 2, while in Vol. 3 there are eighteen upon that subject.

In Vol. 3 Telegraph Companies were concerned in sixteen cases, Electric Light Companies in eighteen, Telephone Companies in twenty, and Electric Railway Companies in twenty-five, or nearly one-fourth the whole number of cases in the volume, a surprising proportion when we recall how recently the electric railway first came into use.

The subject being of such practical and increasing importance in its legal aspects, the convenience and even necessity of keeping abreast of it must be evident to the profession.

Vols. 1, 2 and 3 are now ready. They are handsome books, bound in full leather, well annotated and thoroughly indexed. Price per volume, $6.00.

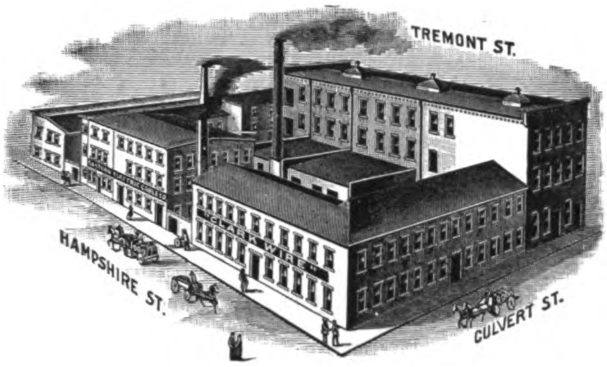
THE "CLARK" WIRE.

In a Letter from the Inspector of the Boston Fire Underwriters' Union, he states: . . . .

"A Thoroughly Reliable and Desirable Wire in Every Respect."



TREMONT ST.
HAMPSHIRE ST.
CULVERT ST.

For Switchboard, Railway and Motor Use, we make all sizes of Stranded and Flexible Wire and Cables with Clark's insulation.

The Clark Wire has been before the public and in use for the past nine years, and has met with universal favor. Thousands of miles of this wire have been sold, and are in use throughout the United States and Foreign Countries, and the demand for it is constantly increasing because it always gives perfect satisfaction.

The Rubber used in insulating our Wires and Cables is especially chemically prepared and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather and is not affected by heat.

We guarantee our Insulation wherever used, Aerial, Underground or Submarine, and our net prices are as low, if not lower, than any other first-class insulated Wire.

We shall be pleased to mail Catalogues with Terms and Discounts for Quantities.

Have You Tried Our NEW CORED CARBON

—FOR—

Series Arc Lighting and Constant Potential Lamps?

IF NOT IT WILL PAY YOU TO DO SO.

The Crouse-Tremaine Carbon Co.,

FOSTORIA, OHIO.

IMPORTANT ANNOUNCEMENT.

We have employed as Superintendent, *MR. A. L. REINMANN, formerly Superintendent of the Sawyer-Man Electric Co.* His ability is known to everybody in the electric light business. Recent improvements made by him, added to the qualities which have already given our lamps such an enviable reputation, easily make the

American Incandescent Lamps

THE HIGH GRADE STANDARD OF THE WORLD.

Quality will tell, and we invite comparisons and tests. Write to us before placing your orders.

Having moved into our new quarters at 250-54 South Clinton Street, Chicago, we are now

The Largest Manufacturers of Telephone Apparatus and Appliances, Exclusively, in the World

WE BELIEVE in producing Apparatus which is strictly Non-Infringing, and frown on patent pirate concerns.

THE NEW LONG-DISTANCE

MICROPHONE (BATTERY) TELEPHONE

OF THE

WESTERN TELEPHONE CONSTRUCTION CO.

is as much superior to any other type of Microphone (Battery) Telephone as our No. 1 Magneto Telephone was to all other magneto 'phones.

The New Exchanges at Newark, O., Johnstown, Pa., Oskaloosa, Ia., and Lansing, Mich., each using 300 of these instruments, we claim to be

The Most Perfect Exchanges of their size in the United States.

The Superiority of Service and Economy of Operation afforded by them have practically resulted in transferring the business from the Bell system to the Western in these cities, notwithstanding the Bell offer of one-half rates.

The Indiana Telephone Company of Indiana, Pa., heretofore a Bell Licensee, have arranged to displace their entire Bell system, connecting 35 points in Pennsylvania, and use hereafter the Western Telephone Construction Co. apparatus.

The Interior Department, Washington, D. C.,

after the most exhaustive examination, tests and trials for telephones ever made, awarded this Company the contract at almost double the price for apparatus of the next highest bidder. The expert committee which made the examination stated:

> "The Western Telephone Construction Company stood above the others, also it was found that not only were the "switchboards proposed to be furnished by the Western Telephone Construction Company free, as far as your com-"mittee are at present aware, from infringement of any patent not owned by that company, but that they em-"body all recent improvements in that line."

Nearly 100 are in use in U. S. Patent Office, displacing Bell system.

MANUFACTURING EVERYTHING

necessary for the complete equipment of a Telephone Exchange, we can assure those who contemplate purchasing instruments that they will save time and money by dealing directly with us, as we have ample facilities, and have had abundant experience in all departments of telephone work.

Western Telephone Construction Co.

☞ **NOTE—Beware of the falsehoods and misrepresentations of competitors who dare not give a public list of their exchanges, but pretend to have "letters, etc.," which they show. Write direct to parties and ascertain the truth.**

YOUGH STEAM PUMPS.

MANUFACTURED BY

BOYTS, PORTER & CO.,

Connellsville, Pa.

SEND FOR ILLUSTRATED CATALOGUE.

Long-Distance Dust Transmitter.

Patented in England and America.

Complete Telephone.

The Original Powder Transmitter and the only one adopted by the English Post Office for public long-distance service all over Great Britain. You can shout in it or whisper in it and get perfect articulation in either case. No limit to the distance they will work.

Claim No. 1 of the "Hunnings" Patent "is in a tension-regulator or means for varying the resistance in a telephone transmitter, finely divided conducting material in a loose and free state."

THE "HUNNINGS"

DUST TRANSMITTER

Does not depend upon variable pressure between electrodes in constant contact. Incorporated as a portion of the Electric Circuit is a quantity of finely divided conducting material or dust, the movement of which varies the current.

We are the only Manufacturers in the United States of the Celebrated "Hunnings" English Transmitter.

Several large exchanges are now using our "Hunnings" Outfit.

The Only Reflector Plate Alternating Arc Lamp.

The Helios Electric Company Claims:

That they have more alternating arc lamps in use than all other makes combined.
They guarantee 80 per cent. more available light than is obtained from any other alternating arc lamp.
They guarantee to give as much light as any direct current lamp using the same number of watts.

Spencer's Improved Alternating Arc Lamp

Possesses the Following Advantages:

Minimum Choke in the regulating coil.
Practically no energy absorbed in the regulating device.
Durability of all its parts; not liable to get out of order.
Can be used successfully on all periods.
Starts quickly.

SPENCER'S DIRECT CURRENT CONSTANT POTENTIAL LAMP

GUARANTEED NOT TO SEE-SAW.

Siemens & Halske Electric Company of America

Siemens & Halske: Berlin, Charlottenburg, Vienna, St. Petersburg

MANUFACTURERS OF

Direct Current Slow Speed Multipolar Generators and Motors.

These machines are constructed with *external armatures*. They have proved remarkably efficient and economical. Used largely in American and European Lighting and Railway Plants. Slow-speed machines, made for direct connection in sizes from 20 H. P. to 2,000 H. P.

ADVANTAGES OF OUR EXTERNAL ARMATURE TYPE:

Maximum peripheral speed of armature with slowest engine speed. Shortest possible winding of armature. Lowest internal resistance of armature.
Only 3 to 4 volts difference of potential between commutator bars. Greatest radiating surface possible. Maximum magnetic effect.
Greatest weight of copper per ampere of current. Armatures cannot burn out. Great compactness.
Correct mechanical design. (The centrifugal force is counteracted effectively by the inward pull of the internal field magnets.)
Finest quality of iron, excellent finish, absence of binding wire.

In 8 years' continuous service not one Armature has been replaced or repaired. **Over 200,000 H. P. in use for Railway, Lighting and Motor Service.**

WORLD'S FAIR DIPLOMA AND MEDAL FOR BEST DIRECT CONNECTED GENERATOR.

MODERATE SPEED BIPOLAR GENERATORS AND MOTORS,

With Siemens Drum Armatures, which are copied extensively in this country. We are building these machines in sizes from 1 H. P to 150 H. P.

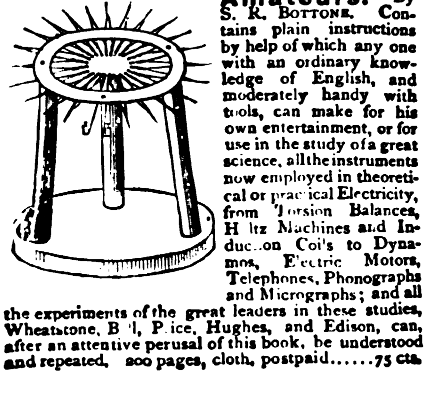
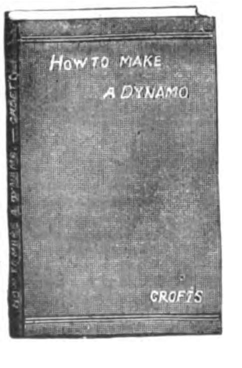
Electrical Instrument Making for Amateurs. By S. R. Bottone. Contains plain instructions by help of which any one with an ordinary knowledge of English, and moderately handy with tools, can make for his own entertainment, or for use in the study of a great science, all the instruments now employed in theoretical or practical Electricity, from Torsion Balances, Holtz Machines and Induction Coils to Dynamos, Electric Motors, Telephones, Phonographs and Micrographs; and all the experiments of the great leaders in these studies, Wheatstone, Bell, P ice, Hughes, and Edison, can, after an attentive perusal of this book, be understood and repeated. 200 pages, cloth, postpaid......75 cts.



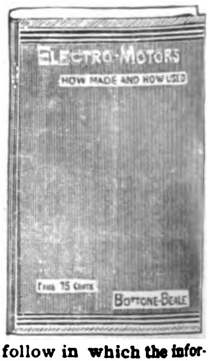
HOW TO MAKE A DYNAMO.

By Alfred Crofts.



A practical work for Amateurs and Electricians, containing numerous illustrations and detailed instructions for constructing Dynamos of all sizes, to produce the Electric Light, containing 96 pages of genuine information which will enable anyone to construct a Dynamo either for pleasure or profit.
Large 12 mo, Cloth, 75 Cts.

Electro-Motors; How Made and How Used.—A Handbook for Amateurs and Practical Men by S. R. Bottone and A. M. A. Beale.—A complete and simple explanation of the source of the power in a dynamo and the method of applying the same, commencing with a Simple Motor, and proceeding to an exposition of the Siemen's, Thompson's, Walker's, Grison and other motors.



In addition three special chapters by an American author follow in which the information embraces all American improvements. The work is probably the most complete and easily understood of any published.
180 Pages, Cloth, price..........75 Cts.

For sale by ELECTRICITY NEWSPAPER COMPANY, 6 Park Place, New York.

The Electric Storage Battery Company

OF PHILADELPHIA, PENNA.,

In addition to all American Patents heretofore controlled, have recently acquired from the

Accumulatorem-Fabrik Aktien-Gesellschaft,

Of Hagen (in Westphalia), Prussia,

All Patent Rights for THE EXCLUSIVE MANUFACTURE of

TUDOR STORAGE BATTERIES

in the United States and are prepared to furnish Batteries of this type of any desired size.

In Germany and Austria the **TUDOR BATTERY** is used in eighty per cent (80%) of all Central Stations—besides being installed in

15 RAILWAY POWER PLANTS and 5000 ISOLATED LIGHTING PLANTS.

TUDOR STORAGE BATTERIES—BOSTON EDISON STATION.

Storage Batteries are Needed in Central Stations:

1st. To effect reduction in the first cost of plant. (Half steam power plant and half Storage Battery Plant costs only three-quarters of what all Steam Plant would cost for same work.)

2d. To convert variable into steady loads. This will save machinery from strain.

3d. To effect a saving of from 20 per cent. to 40 per cent. in coal bills.

4th. To insure reserve power in case of accident to generating machinery.

For particulars address—

THE ELECTRIC STORAGE BATTERY COMPANY,

Sole Manufacturers of the "Chloride Accumulator,"

PHILADELPHIA, PENNA.

EDITORIAL NOTES.

The Railway Convention issue of Electricity (Oct. 16) was entirely exhausted four days after its appearance, with special orders for more than 1,000 copies still on the books.

The type is now being reset, and a second edition will be printed this week.

Any further orders for extra copies should be sent in at once.

The people know a good thing when they see it, and the best thing in the trade-paper line last week was Electricity.

An Unfortunate Mistake at Atlanta.

One of the most regretable mistakes of the administration at the World's Fair was the granting of a monopoly of the photographic privileges to the highest bidder. Had this highest bidder been a competent artist it would have been bad enough, but as it happened then, and is likely to happen again, the highest bidder was by no means proficient in the art, and were it not that the restrictions were relaxed somewhat towards the end of the Exposition so that outside artists were, under certain conditions, permitted to ply their trade within the grounds, the world would to-day be without a presentable photographic record of that most beautiful of all architectural triumphs.

But entirely aside and apart from this aspect of the case, the concentration of the camera privileges in the hands of a single individual or company was an unfortunate mistake. All enterprises such as this are dependent upon popular favor, and the press—the illustrated press more than any other—is necessarily a potent factor in arousing popular interest. The World's Fair management spent hundreds of thousands of dollars in advertising, and yet after all this was done placed an embargo upon a class of advertising which was at least quite as effective, but which cost them nothing. The illustrated press, technical and otherwise, with commendable enterprise, sought to lay before its readers pictorial representations of the grand display. This they were willing and anxious to do without cost to the Exposition, but they wanted good photographs, and these they could not buy from the official photographer, simply because the latter could not take good photographs. In some cases they offered to pay the official photographer as much as he charged for his prints for the privilege of sending their own artists there to do the work in their own way, but even this proposition was declined, and they had to take what they could get or go without.

Another annoyance that was the outgrowth of this arrangement was this: Among certain classes of papers, chiefly the technical press, there is and was an intense rivalry and a constant endeavor to outdo one another. It happened more than once that one electrical paper, for instance, employed the official photographer at extra expense to take a given view, and that a rival procured prints from this same negative, either simultaneously with or before the party for whom the picture was taken.

One noteworthy instance is called to mind. The General Electric Company had promised all the electrical papers that if they would refrain from illustrating the tower of light until the proper time it would, at its own expense, have a large photograph taken and distribute it to them all simultaneously. The papers respected this request, and one Sunday when Electricity Building was closed to the public the photograph was taken. Copies were to have been distributed on the following Wednesday afternoon, but lo and behold, one of the papers, more enterprising than the rest, or having more pull with the official photographer, appeared at noon that day with a full page half-tone made from that same negative.

These are but a few of the occurrences that were the almost inevitable consequence of the policy pursued. The mistake was so fully realized that towards the latter part of the Exposition the directory did all that it could to rectify the evil.

We are surprised that in view of the general recognition of the mistake made at the World's Fair, the officials of the Atlanta Exposition should have committed the same blunder, only in a more offensive form.

It seems that there, too, there is an Official Photographic Company, and this one is clothed with more autocratic powers of censorship than was even that one at the World's Fair. Before the illustrated press can make even so much as a sketch on the grounds, it has to make application to this photographic company, agreeing as follows:

"That all pictures taken shall be submitted to the Official Photographic Company, which shall decide (sic) if it is the desire of said company to copyright such picture, which said company may do, that should we" (the press) "desire to purchase from said official company any copyrighted photographs" (even if they be our own photographs) "we will preserve the same from any other use than that for which they are bought, to wit, for illustrating said Exposition in the columns of said publication only;

that after any negatives bought from said company have served the purpose of illustrating, all such negatives shall be destroyed: that we will not permit any such negatives to be used in any other publication whatsoever."

In the first place this is asking the illustrated press to promise that which they cannot fulfil. In the second place, such restrictions as these will kill the goose that is expected to lay the golden egg. It is the shortest sighted policy possible, and we regret exceedingly that the Atlanta Exposition authorities have been led into this mistake. We feel sure that unless this obnoxious and unreasonable restriction be abrogated, the pictorial press will let the Atlanta Exposition severely alone. Better could the authorities require of the Official Photographic Company, in consideration of their privileges, that they furnish free to properly accredited representatives of the press all the photographs they wanted. The illustrated press does not ask this, however. It merely asks unrestricted privileges of taking their own photographs in their own way and at their own time. Unless this be granted, it is certain that the Exposition must suffer.

* * *

Franklin Leonard Pope. On Monday morning, October 14th, the electrical world was inexpressibly shocked to learn from the daily press that Franklin Leonard Pope had been killed in his own home at Great Barrington, Mass., by electric shock from accidental contact with the high potential alternating current mains.

That the contact was accidental, and not through carelessness or ignorance, was of course apparent to every one, for no one was more familiar with the apparatus and the precautions necessary to its handling than Mr. Pope himself. It was he who first brought the alternating current to this country, having, as the representative of the Westinghouse Company, purchased the original Gaulard and Gibbs patent. Further than this, the Great Barrington plant was Mr. Pope's own creation, he having recently remodeled it and changed it over from a three-wire direct current to the high potential alternating current, so that every detail was personally known to him.

As general manager of the installation he had obtained a special permit to have the transformer located in his cellar in order that he might the more conveniently make the necessary tests and watch the operation of the circuits.

On Sunday evening, upon turning on the lights in his house, they failed to come to full brilliancy, and it was this defect that led Mr. Pope to go to the cellar to detect and remedy the fault, if possible. A few minutes later, members of his family, hearing a fall, went to the basement and found him a corpse. Medical aid was promptly summoned, but all methods of resuscitation proved unavailing.

Just how he came to his death is still and will probably remain a matter of conjecture, but careful tests of the transformer and circuits, made shortly afterwards by Messrs. Edward Weston and Wm. Stanley, showed that the primary was grounded outside the building, and also on the secondary and on the transformer case. The marks on the body consisted of a slight burn on the knuckle of the thumb, a long scratch-like burn around the base of the thumb, and a slight burn on the index finger. There were no burns on the soles of the feet, but the soles of his shoes were perforated with many small holes as though pierced with bird shot.

In another place we give the theory of the accident which is held by his brother, Mr. Ralph W. Pope. We understand that Messrs. Weston and Stanley do not agree entirely with this, and it is probable that their version may appear in our next issue.

Death in any form is always a sad thing, but when it comes suddenly, although it may be painless, it seems to carry with it among those who survive greatly intensified emotions. When, also, it strikes a man so prominent in the community and so respected as was Mr. Pope, the loss becomes a personal one to a very much broader circle than could otherwise be the case.

There does seem a gruesome irony in the fate which chose as its victim one who had done so much with and for the very agency that caused his death. This is, we believe, the first case on record where one thoroughly conversant with the dangers attaching to the high potential current has met death at its hands.

Mr. Pope was in his 56th year, and during a long and successfu professional practice of the most varied character so conducted himself as to command the love, respect and confidence of all with whom he came in contact. His sense of honor was of the highest order, and in his honorable career he has left his family a legacy far more precious than mere worldly wealth. Appearing often before the courts as an electrical expert, he was such in the highest sense of the word, and looked with disgust upon those who prostituted that high office to personal ends. So strong were his feelings on this point that when we, some months ago, attacked in unsparing terms the practice of electrical experts appearing really as associate counsel, in violation of their oaths, Mr. Pope wrote us a highly appreciated and appreciative letter, endorsing the stand we had taken.

We are among the mourners for Mr. Pope's death, and as such we extend the most heartfelt sympathy to those who have not only lost what we have lost, but who have also been bereaved of a husband, father and brother.

* * *

Thoughtless Criticism. Our esteemed contemporary, *Electric Power*, has an editorial in its last issue, under this title, which reads as follows:

> In most of the discussion that has taken place since last February regarding the application by the Niagara Falls Power Company to the city of Buffalo for a franchise for the use of the streets for the purpose of distributing power, it seems to have been freely assumed that the Niagara Company was bluffing when it refused to state a limiting price for its power previous to any grant, and that engineers stood ready at any time to determine the losses in transmission, and that, of course the company must know what the installation was to cost.
>
> Now, granting that all these facts were perfectly well known to the company, will some one inform us how they were to determine what to add to such losses and charges for cost of franchise in the way of payment to the city, or how to determine the fixed charges when it was not known what sort of construction for carrying the conductors would be demanded by city authorities? People, and sometimes engineers, are thoughtless.

Referring to the last paragraph, we have this to say. When the Niagara Company made its first offer to the city of Buffalo to sell to the latter undeveloped power, power on the turbine shaft, or electrical power at the terminals of the dynamo at Niagara, for $10, $13 and $18 respectively, did it not know that however desirable such a consummation might be to itself, it was not a commercial proposition for the city of Buffalo?

Does *Electric Power* not know that in the Niagara Power Company's original letter to the Common Council these words were used: "The company cannot name a price for electrical power transmitted to the *Buffalo line*, as in the question of *transmission* are involved the uncertainties of the losses and cost of operation and maintenance"?

If the editor of our contemporary does know this, why does he bring in the question of cost of franchise and other city expenses, which are not involved in the question at issue at all?

The Niagara Company in this same letter states that it "has made a contract with a large electrical power user for not less than $20,000 per annum for 1,000 electrical H. P. developed on the company's land."

Now the distance of transmission in this case was less than a mile. For this transmission the Niagara Company have added $2 per H. P. Assuming the distance to have been just a mile, and that increase be maintained for further distances, there would have to be added 15 × 2 = $30 for a H. P. delivered at the Buffalo city line, making $48 as the cost at that point. This may be and probably is, an unfair way of estimating the cost at Buffalo before distribution, but the Niagara Company seemed to fear that its statement that it had contracted to deliver power at a distance of less than a mile in 1,000 H. P. lots at the rate of $20 would not be believed, for it adds: "As this statement has been called in question, the company *now offers to submit* this contract to the inspection of the Mayor of the city of Buffalo."

But when we consider that the power when delivered at Buffalo is not yet in an available form, but must be transformed down, and when distributed in this transformed state is still not in an available form for the customer, but requires an additional investment on his part in the way of further transformers, motors and wiring, making an investment nearly or quite equal to that of a steam plant, it is not clear how either the Niagara Company or the city of Buffalo could afford to sell power even on a 24-hour basis in competition with steam. But when we consider 10-hour power, such competition would seem to be entirely out of the question.

It must be remembered that by far the largest number of power consumers use it not more than 10 or 12 hours a day, and that absolutely none of them ever use it 24 hours a day for 365 days in the year. The Niagara Company's figures have thus far been exclusively on a 24-hour and 365-day basis, so that no matter what figures they have given, or may give, they are meaningless on a horse-power hour basis because it will never be used to the limit.

It is not, therefore, that the engineers who have condemned the Niagara scheme are thoughtless, as our contemporary suggests, but that those who have accepted it as a commercial project are thoughtless, or worse.

* * *

The Railway Convention. It is to be hoped by every one interested in the success of the street railway industry, and this should mean about every man, woman and child in America, that the Montreal meeting of the American Street Railway Association has marked a turning point in the history of that body. The Convention at Atlanta last year, from an educational standpoint, was a flat failure, as was reported in ELECTRICITY at the time. The one at Montreal, viewed in the same light, was little better than a failure; yet at the latter meeting there were conspicuous signs of a new life, of renewed interest on the part of those whom the Association was primarily designed to benefit; and when the railway companies make voluntary contributions of over $4,000 to cancel the debt of this Association, it shows conclusively that, even if the body has so far failed to accomplish its mission, there is strong hope that it may go forward to full accomplishment.

The trouble with the Association seems to have been that it got into a rut. Long after the railway men discarded horses and adopted electricity, their National Association continued to be run on the horse-railroad plan.

But after the Montreal awakening all criticism should cease. Our railway friends must have a fair show, and we recommend them to copy somewhat the National Electric Light Association, which of late years has been admirably managed.

It is not enough that first-class papers are prepared, read by title, and afterwards distributed among the members and printed in the journals. These papers should be read in full at the meetings, and DISCUSSED. There is no more effective way to disseminate knowledge than by a thorough discussion of the papers presented. And in the discussion last week of the question of admitting supply men as members, it was conclusively shown that the Railway Association has fully as ready and bright talkers as any other body.

Give them a chance to talk, not on a really dead question, but on live issues, and every railway man in the country will realize that he cannot afford to be absent from these meetings.

As to the arguments pro and con on the supply men question, few of them were new. One, however, seems worthy of some comment. This is that the *supply* men should be kept out because the railway men desire to discuss a great many of their affairs in secret session. This embodies the height of absurdity.

What in the name of Joel Hurt have the railway men in their bosoms which will not bear the light of day? What have they to fear from open confession of trouble and sin?

American railways are managed by public corporations; their affairs *cannot* be kept secret. ELECTRICITY will agree to print every detail of the business of any one of them on very short notice.

We don't believe the supply men can do the American Street Railway Association any harm. The money of the supply men is good money, and the Association needs it.

The Propagation of the Magnetism of Iron.*

BY W. PEUKERT.

When a long straight iron bar is excited by a magnetizing coil situated at the center, the lines of force, all of which pass through the coil, do not keep in the iron up to its extreme end, but emerge into the air at all points along its length, so that the induction in the bar falls off continuously as the distance from the central source of magnetization is increased. With a periodically varying magnetizing force the same effect is produced, and, moreover, the corresponding periodic changes in the induction induce eddy currents in the iron. These cause a lag in the phase of the induction which increases as the end of the bar is approached.

Experimental proof of this was carried out on rods of about one meter length of wrought and cast-iron, and on a large bundle of soft iron wires of 1 mm. diameter. The induction at various points was measured by search coils placed at intervals on the bar, and readings of the instantaneous values of the induction were taken through a complete period for each coil. The readings were obtained by means of a contact-maker fixed on the alternating-current dynamo used for exciting the magnetizing coil, the momentary currents being indicated by a Wiedemann galvanometer. Magnetomotive forces of 288 and 1,306 ampere-turns were used.

The curves of induced E.M.F. obtained from all three samples show a shift of phase which increases with the distance of the search coil from the center of the bar, both at the lower and at the higher values of the induction. The curves are not symmetrical with the zero axis, the difference being attributed to residual magnetism. There is no marked difference between the changes of phase produced in the solid and in the laminated specimens, the amount of shift not being sufficiently clearly defined to show any distinct difference. The magnitude of the deflections continuously falls off along the bar, showing the diminution in the induction.

An Electric Theory of the Solar System.

M. C. V. Zeuger, professor of astronomy and physics at the Prague Polytechnic School, contributed a paper on this subject at the recent meeting of the Association Francaise pour l'Avancement des Sciences at Bordeaux. M. Zeuger has been experimenting with a hollow copper sphere suspended in an asymmetric field produced by one, two, or three electro-magnetic poles, and finds that the movements of the sphere present an absolute analogy to the motions of the planets. He proposes, therefore, "to replace Newton and Kepler's laws by the law of Gauss." It follows as a consequence of the theory that the periods of revolution of the planets and comets must be a multiple of half the period of rotation of the sun, and a similar law would apply to the revolutions of satellites round their primary, except in so far as they may be affected by perturbations of the sun or other planets.

* Abstract from the *Elecktrotechnische Zeitschrift*, Sept. 19.

GENERAL ELECTRIC'S FINANCING POLICY.

Northwest General Electric—The Scheme, the Companies Financed, the Facts and Figures from the Official Record.

HOW BONDS ARE MANUFACTURED FOR NEW ENGLAND INVESTORS.

CHAPTER XIV.

The Owatonna Electric Co.—II.

In our last week's analysis of the affairs of the Owatonna Electric Company, it will be remembered that we showed from the official records a deficit for the year ending December 31, 1893, of $8,280.37 in operation. This, we think, disposed of any claim that the earning capacity of the plant justified the capitalization of $50,000.

In the official balance sheet as printed the plant account was placed at $61,611.98, this being the amount which outside stockholders were led to believe was the value of the plant.

We present this week the inventory of all the property owned by the company two years after the money was raised from the sale of bonds, which is presented herewith. The valuations are made by experts, and we challenge any one connected with the Northwest bond steal to dispute their accuracy:

OWATONNA ELECTRIC COMPANY, OWATONNA, MINNESOTA.

SCHEDULE OF PROPERTY: MARCH 1, 1893.

(Photographs and Plans on File.)

REAL ESTATE.

Lots 8, 9 and 10 in block 3, McNamara's addition.
Brick station, 86 ft. 4 in. x 43 ft. 4 in.
Including engine and dynamo room, 40 ft. x 46 ft.
" boiler room, 40 ft. x 36 ft.
Frame building (former station), 20 ft. x 40 ft.; coal shed, 14 ft. x 64 ft.

POLE LINES (ERECTED).	
159 30 foot poles. 76 40 " " 295 4 pin cross arms. 900 glass insulators. 100 break arms.	
LINE WIRES.	
4,200 feet No. 8 pressure wire. 4,200 " " 10 " " 2,640 " " 12 " " 4,200 " " 1 Okonite. 700 " " 1 weather proof wire. 26,580 " " 6 Okonite wire. 1,800 " " 4 " " 25,540 " " 6 K. K. " 5,000 " " 8 " " 2,160 " " 10 " " 390 " " 4 Habirshaw wire. 1,500 " " 10 " " 5,000 " " 6 weather proof wire.	$6,730.00
ELECTRIC PLANT.	
One L. D. arc dynamo, No. 2,999; capacity 50 1,200 C. P. lamps. Two A. 6 alternating dynamos, Nos. 118, 241; capacity 650 16 C. P. One 188 exciter dynamo, No. 996. One 18 exciter dynamo, No. 1,168. One oak switchboard, 8 ft. x 8 ft.	$4,125.00
INSTRUMENTS.	
One ground detector, No. 416, Class A. Four current indicators, Nos. 5,425, 5,429, 5,421, 4,437, 40 amperes. Two potential indicators, Nos. 2,134, 2,153, 64 volts. One rheostat, Type 148, No. 12,601. One " " 165, No. 15,699. One " " 148, No. 13,042. One " " 165, No. 15,700. Two transformers, F, Nos. 30,924, 30,928, Class F. S, 1,000 volts. Four 1,000-volt feeder-boards. Two two-circuit D. P. switches, 1,000 volts. Two single pole exciter switches. One four-circuit arc plug board. Four Type F lightning arresters, Nos. 2,994, 3,020, 3,019, 3,036. Four Thomson's Type A lightning arresters, Nos. 9,102, 9,107, 4,760, 4,708. One automatic regulator, No. 3,140. One ammeter, No. 1,037. One spring jack. One magneto. Fifty arc lamps, 1,200 C. P.	$2,050.00
TRANSFORMERS (ERECTED).	
Eleven 5 light; seventeen 10 light; five 12 light; fifteen 15 light; four 20 light; fourteen 25 light; three 30 light; eight 40 light; one 50 light; one 75 light. Total, 79.	$3,437.00
METERS.	
Forty-five 10 ampere; twelve 15 ampere; one 25 ampere; thirty-five 30 ampere; five 50 ampere. Total, 98.	$1,349.00
Total..	$17,691.00

Brought forward	$17,691.00
STEAM PLANT.	
One McIntosh & Seymour compound engine, 10½ in. x 16 in. x 12 in. One Ideal single cylinder engine, 19 in. x 12 in. Two Babcock & Wilcox water tube boilers, 184 H. P. One iron smokestack, 42 in. x 70 ft., with cast iron base. Two Davidson steam pumps, 5 in. x 3¼ in. x 8 in. One Wainwright water tube heater, 200 H. P. Three new belts. Two old belts. One Hazleton tripod boiler, 100 H. P., (Old Station). One Robinson & Cary boiler, 4 H. P., (Old Station). One Phœnix Iron Works heater, (Old Station).	$8,125.00
TOOLS AND FIXTURES.	
1 iron coal dump car; 1 platform Howe scale; 230 feet of track; 1 16 ft. ladder; 1 8 ft. ladder; 1 4 ft. ladder; 5 pole spuds; 1 blow torch; 1 pair of climbers; 1 filter; 2 60 gallon Hub oil cans; 1 waste can; 1 sealing tool; 1 12 in. bellows; 1 set of ½ in. rope and tackle; 1 5 ft. crowbar; 1 spoon shovel; 1 round point shovel; 1 tree trimmer; 2 18 in. x ⅝ in. bitts; one 1½ in. chisel; 1 bracket saw; 1 corner brace; 4 socket wrenches; 2 cast iron wrenches; 3 monkey wrenches; 2 Stillson pipe wrenches; 1 pair tinner snips; 1 pair pliers; 2 spanner wrenches for arc lamps; 2 spanner wrenches for engine; 5 cast iron wrenches; 1 socket wrench for pump; 50 feet ¾ in. hose; 50 feet linen hose.	$314.05
SUPPLIES ON HAND MARCH 1, 1893.	
500 carbons. 40 16 C. P. incandescent lamps. 70 32 C. P. " " 2 fan motors. INSIDE WIRING MATERIAL. 1 roll No. 10 Okonite wire. 1 " " 16 " " ½ " " 12 " " 100 feet No. 10 Grimshaw tape. ½ roll " 14 Okonite wire. 1 " " 8 K. K. " 1 " " 6 " " ½ " " 6 weather proof wire. ½ " " 18 " " " 30 yards No. 16 cord. 10 porcelain rosette cutouts. 15 key sockets. 5 5-ampere switches. 12 curved cutouts. 6 25 ampere M. L. cutouts. 2 10 " " " 4 rolls tape. 2 colored arc globes. 5 clear globes. 4 opal globes.	$808.65
	$26,438.70

The above showing disposes of any possible claim that there was any such value in the plant as would justify the capitalization. In further proof of the slight basis upon which Byllesby and Coffin sought to raise $50,000 of money from ignorant investors, we present herewith a reproduction of the station plan. Those familiar with the business will recognize at once the justice of our charge of gross swindling in connection with this Owatonna plant.

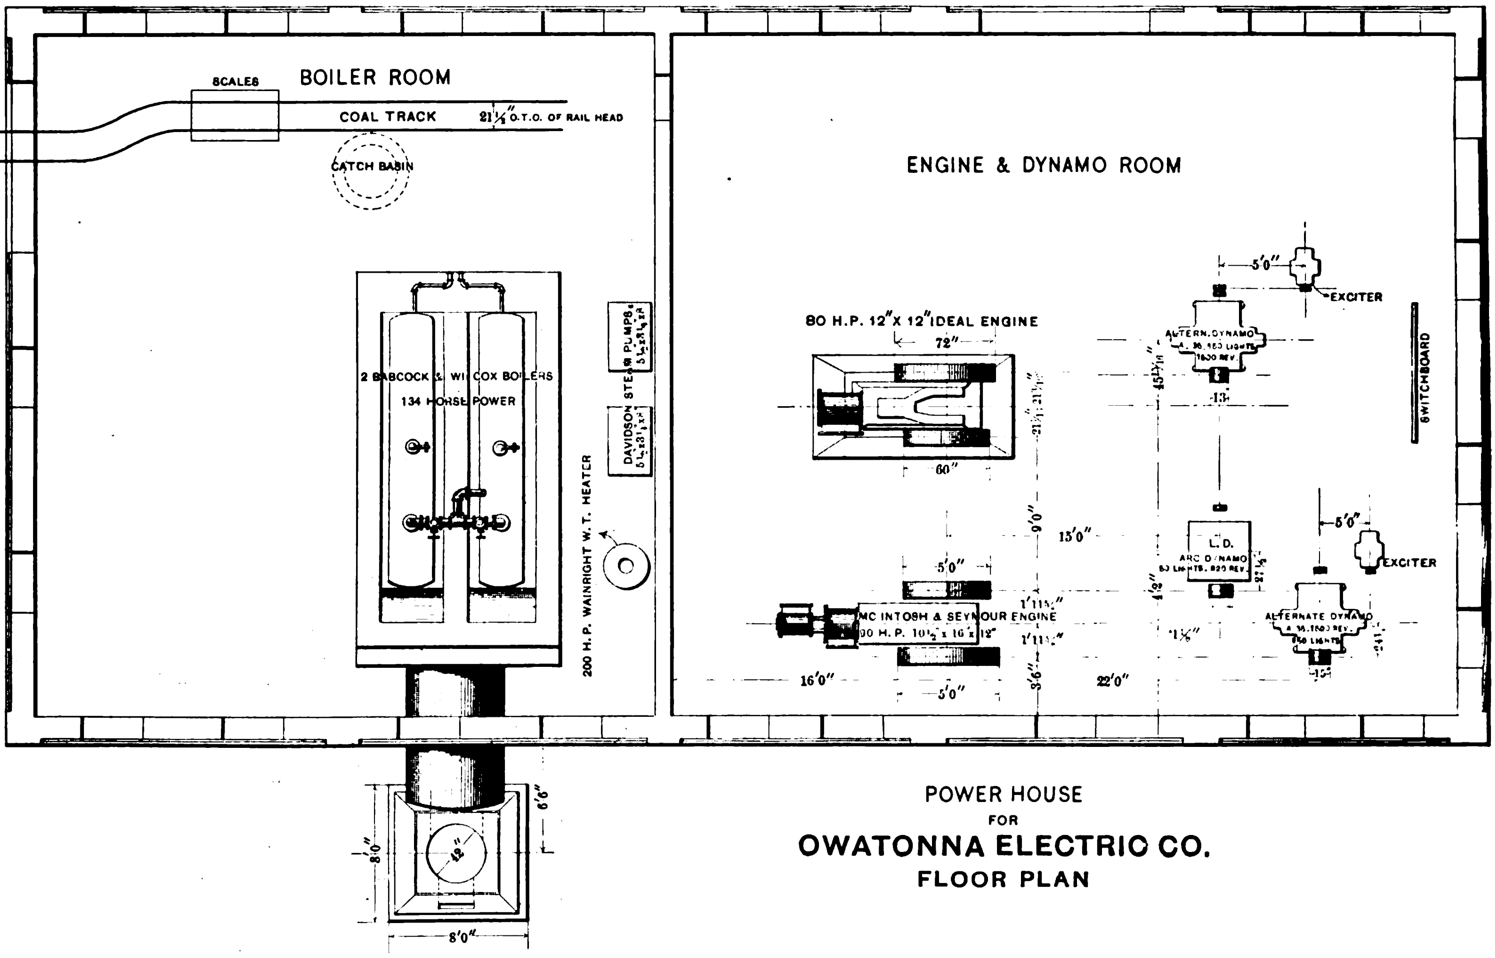
It is more than difficult to conceive how any manufacturing company, working on legitimate lines, could have taken the Owatonna electric plant as a groundwork upon which to float an issue of bonds. The town was small, with no prospect of rapid growth. The plant had lost money from the beginning, and would have been closed down had it not been for the application by Mr. H. M. Byllesby of Mr. C. A. Coffin's great plan of financiering. Neither of these gentlemen was ignorant of the situation of this company, nor of the general conditions of the electric lighting business. They knew that the ultimate end must be failure. Their only object was to raise money, no matter how or by what methods—to prolong a swindling game as long as possible.

The Owatonna Electric Company was saved from a receivership because the bondholders knew that the expenses of such a proceeding would only swell the losses. The plant was finally sold to Mr. Geo. C. Duffie for $12,000, and has since been disposed of by him. Thus there was left to divide by the Northwest General Electric Company $12,000 against the following:

Notes		$29,981.66
Bonds		25,000.00
Total		$54,981.66
Add plant account	$61,611,98	
Less notes	29,981.66	
		31,680.31
Total		$86,611.98
Deduct the proceeds of sale		12,000.00
And we have a loss of		$74,611.98

of some one's money for their pleasure in becoming acquainted with the grand Coffinesque scheme of exploiting work and lending assistance to local enterprises.

Next week we shall take up the affairs of the Austin (Minn.) Electric Company.



POWER HOUSE
FOR
OWATONNA ELECTRIC CO.
FLOOR PLAN

THE PROPOSED MAGNETIC UNITS.*—V.

To the Editor of THE ELECTRICIAN.

SIR: When any one presumes to offer an opinion on such a subject as this, either he should be a well-known man whose views already have weight in the estimation of others, or he should present some credentials to show that although his qualifications may not be generally recognized, yet he has entered into the matter sufficiently and done enough work in the field to show that he ought to know what he is talking about.

Although I have written a good deal on electrical subjects, it has been almost entirely on what is called the practical side, and, therefore, when attempting to say anything publicly on a theoretical question, it is perhaps desirable to mention briefly the grounds on which my opinions are formed, and the nature of the practice which has led me on to form those opinions. This is my apology for entering rather more fully into personal matters than modesty would dictate under other circumstances. I also think that often general truths are better conveyed in a personal narrative, particularly when they are of a complicated and debatable nature. . . .

Now, as I do not pretend to be an original thinker, I have had to go for my knowledge to standard works, and of them I have found none which can bear comparison with Dr. Lodge's "Modern Views of Electricity" and Mr. Oliver Heaviside's "Electromagnetic Theory" for giving clear and comprehensive views on theory, and no work on the practical side to compare with Mr. Kapp's two volumes. The great value of other works, such as Dr. Fleming's, I also thoroughly recognize, but the above works I have gradually come to constitute my standards, as I have found them the most helpful in case of need and difficulty. In speaking thus I do not for a moment wish it to be understood that I understand everything Dr. Lodge, and especially Mr. Heaviside, say. I only wish to have it inferred that, so far as I have been able to understand them, I have found their views and explanations reliable and of the greatest value, and having fully ascertained this, I naturally am ready to accept their lead and guidance in further developments, which in some measure may be beyond my scope.

Now, in all my work in this field I have felt more and more the absolute necessity of a clearer understanding and definitions of electromagnetic quantities and actions. It is possible to wade through the design of an alternator by the use of various 10^8ths or 10^9ths, plus or minus as the case may be, and with the aid of that horrible mystifier the "coefficient of self-induction," which has played such a conspicuous part the last few years; but it is not the right way to go about it, and it is all the more roundabout and difficult when one tries to explain results to others. Things must have names if they are there, and the simpler ones the better, and the magnetic units have just as firm and as sound a basis as the physical ones.

Most alternating work is now designed in a rough manner, and without attention to the finer points, and this is why the efficiency of alternating plant is not as good as it should and might be. Again, to this confusion about electromagnetic quantities, and the basis on which they rest, is due the fact that people not clearly grasping them cannot measure them accurately, and do not feel proper confidence in the results even when they are properly measured.

To introduce certain units which define these quantities, and allow them to be explained clearly, is, therefore, not to add to complication, but to get rid of it, and besides that the everyday problems of electricity would be much better treated by the use of such units and the banishing of that miserable term "lines," and the inaccurate and misleading ampere-turn into the background.

I must own that I found so many new terms very confusing when I commenced to read Mr. Heaviside's work, but then I put this down to my own ignorance, and not to want of lucidity on Mr. Heaviside's part, and in time I came to see that that was the correct view. Having found Dr. Lodge and Mr. Heaviside sure and reliable guides in this difficult but interesting and most important field; having found that they understood and could explain problems which I see will soon be of the greatest practical and commercial importance, and they having found certain names and units desirable in order to explain and deal with these problems, it, to me, savors rather of ignorance and insufficient acquaintance with the subject than of anything else to say that such terms are not needed, and that the old ones are good enough.

As to the precise values which are to be taken as units, I am perfectly content to leave this to those who have made theory a special study, particularly as I think it probable that in another ten or fifteen years it will be found advisable to make a fresh start with a complete new set of electric and magnetic units, arranged on such a basis as Mr. Heaviside has indicated. Consequently I am not prepared to split hairs over the question of dimension, but there is no reason why the quantities themselves should not be defined in some definite and understandable unit as soon as possible, so that they can be thought, talked and written about with facility.

I trust, therefore, Dr. Lodge will not be discouraged at the cold reception he has met so far. It appears to me that his work is not only a good one, but has been exceedingly well done, and although I do not quite agree with him, especially on the 4π question, on which I side entirely with Mr. Heaviside, particularly from an educational point of view, yet I consider such matters of secondary importance as compared with the necessity of quickly and intelligibly defining magnetic relations and quantities. Apologizing for the length of this letter,

Yours, etc., G. L. ADDENBROOKE.

---

*From the *Electrician* (London).

FRANKLIN LEONARD POPE.

Franklin Leonard Pope was born in Great Barrington, Mass., on December 21, 1840. His parents were Ebenezer and Electa Wainwright Pope. His father is described as one who did his own thinking, read the daily papers with avidity and could talk intelligently upon any of the questions of the day. He was distinctively a humorous man, and gave to his children a large inheritance of wit and humor. His mother was a strong-minded, though not a masculine woman, with strong individualities which, like the father's humor, were inherited by Frank. The paternal grandfather, Captain Ebenezer Pope, was in his day a very prominent citizen of Berkshire, and served several terms in the Legislature. On his mother's side his ancestors were equally worthy.

Frank's early education was that of the average New England youth of those days, with the addition of one term at Amherst Academy. His favorite studies were natural philosophy and geography, and at an early age he evinced a fondness for drawing and scientific and mechanical pursuits.

The first money he ever earned was the product of his pencil—it was 25 cents given to him by a railroad engineer for a sketch of his engine. This led to a somewhat lucrative business on a small scale in the same line, for his skill in drawing brought him orders for sketches of other engines on various roads centering in Great Barrington.

Next we find him editing and publishing, in connection with Merritt I. Seeley and Tom Maguire, a small local paper called the *Berkshire Rambler*. The youthful editors were their own compositors and newsboys. This paper, it seems, was dedicated to "Honesty and Justice," two watchwords which characterized Mr. Pope's after life so distinctively.

In 1857 a branch of the American Telegraph line was extended from Pittsfield to Great Barrington, and of this Mr. Pope was appointed operator. He had charge of the office until 1859, when he was appointed circuit manager of the Boston and Albany Railway wires at Springfield. At the close of the year there was a consolidation of rival telegraph companies, which threw many operators out of employment, but such was Mr. Pope's skill that he was retained and assigned to Westfield. He, however, soon after resigned in favor of one of the unfortunates who had a family on his hands and needed the position more than he did.

Going to New York, his skill with the pencil again availed him, and he secured a position as artist with the *Scientific American*. He also at this time imbibed much information in regard to the patent business which afterward was to become of much use to him.

At the breaking out of the war Mr. Pope re-entered the telegraph service and was assigned to Providence, R. I., where for a year he acted as operator for the American Telegraph Company. He was next transferred to New York, with instructions to prepare a complete series of maps of the company's system of telegraphs, which then embraced all the lines in the seaboard States from Maine to Virginia. This occupied him for two years, and resulted in a map including the smallest details of the whole system—a thing unique at that time in telegraphy. So valuable was his work in this line that he was next detailed to examine all of the different kinds of telegraphic apparatus then in use and to decide upon a standard. He was interrupted in this work by the New York riots. The lines were torn down and communication interrupted. Mr. Pope again was the man to fill the breach, and by appointment from Gen. Lefferts he undertook to re-establish the wires to Boston. Disguised as a farmer, and with a portable telegraph instrument and tools for repairing lines concealed in a sack of oats, he started from New Rochelle under cover of darkness and fog. He walked over the fifteen miles between that place and the Harlem River, and by daylight succeeded in connecting a single wire and restoring communication. During that night he had many hairbreadth adventures, but his indomitable pluck and perseverance brought him through all right.

In 1864 young Pope finding his health seriously impaired, in the hopes of regaining his strength, accepted an appointment as assistant to Col. C. S. Bulkley, engineer-in-chief of the Russo-American Telegraph Company, and in 1865 he went to San Francisco to investigate the practicability of connecting the United States with Europe by means of a telegraph line via Behring Strait. His preliminary investigation disclosed the fact that the country over which the proposed line was to pass, from Fort St. James, on the upper waters of the Frazer River, to Behring Strait, a distance of 1,500 to 2,000 miles, was an absolute *terra incognita*, rendering necessary a preliminary exploration and survey of this whole country. He recommended that the survey be undertaken by two parties, and this plan was adopted, Pope himself being placed in charge of one of them. The greater part of the winter of 1865 he passed on Lake Tatla, suffering many hardships, but nevertheless prosecuting his work.

Returning in the spring, he was next ordered to Kamchatka to prosecute further explorations there, but before he could start the successful completion of the 1866 Atlantic cable caused the abandonment of the scheme.

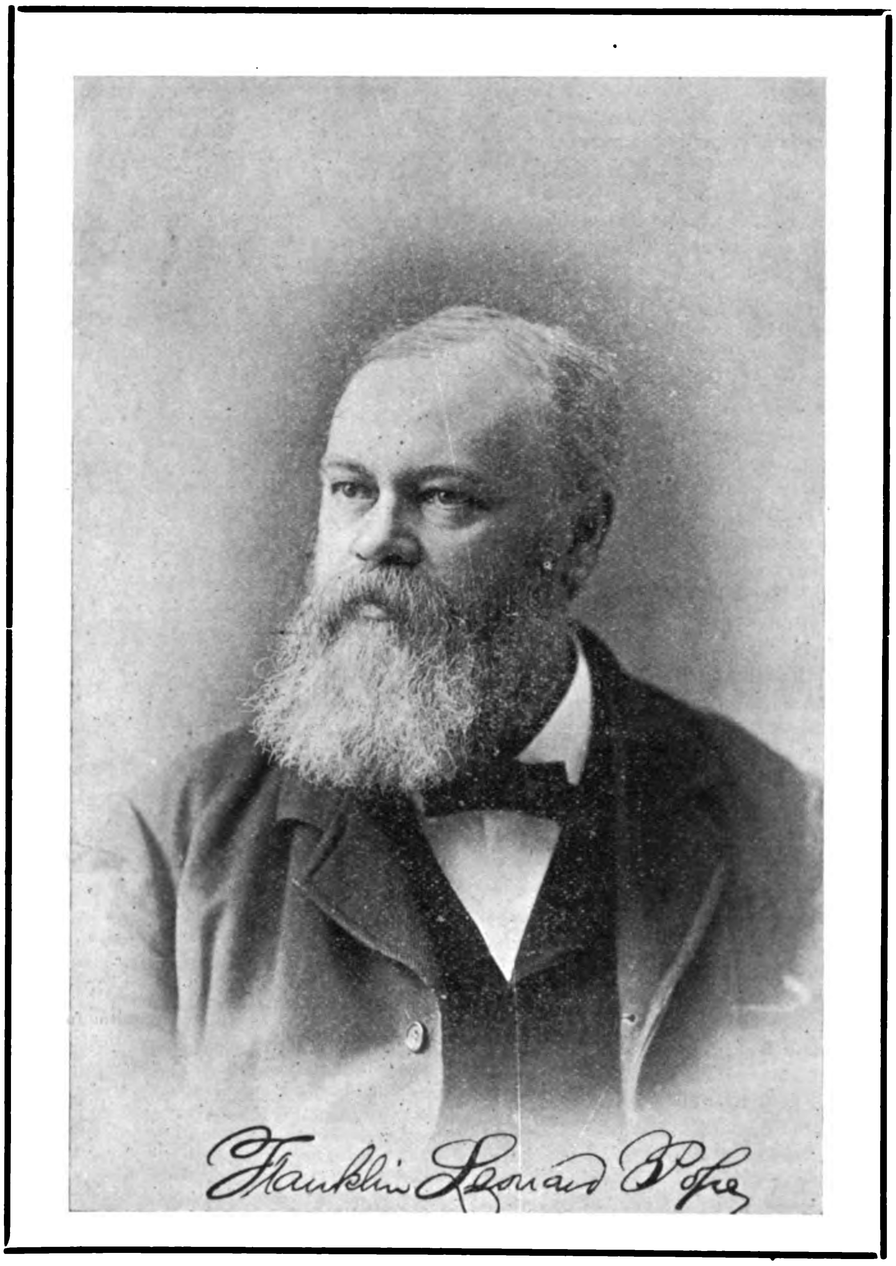
His work was not lost however, for when the surveys for the Canadian Trans-Continental Railway were made his notes proved of the utmost value in determining the best route to the Pacific in British territory.

After returning from Alaska, Mr. Pope was employed for some time as editor of *The Telegrapher*, a journal devoted to telegraphic interests. It was at this time that he wrote "The Modern Practice of the Electric Telegraph," a hand-book which at once became standard, and has passed through several editions, being used as a text-book in the United States Signal Service and in the military telegraphic service of the Government.

In 1867 S. S. Laws invented his stock-ticker. It was a failure as a system until Mr. Pope was called in to perfect it, since which time it has met every requirement, and two years afterward was sold to a company for $100,000 and a royalty of $10,000 per year in addition.

Soon after this business passed into other hands Mr. Pope invented a type-printing instrument, so simple that a child could work it after five minutes instruction. The inventor, with the assistance of his brother Henry, soon established quite a profitable business in constructing private telegraph lines equipped with these type-printing instruments. The business increased so rapidly that he was obliged, through want of capital, to form a company to carry it on. The Gold and Stock Telegraph Company of New York finally purchased a majority of the stock of this company, and consolidated it with its own, eventually developing an enormous business in private telegraph, extending to all the principal cities of the United States.

Electric railway signaling apparatus next attracted his attention, and in this line of work he was, from a technical point of view, almost equally successful,



but almost endless litigation has prevented satisfactory financial outcome. His systems have been employed on the Boston & Albany, Eastern, Old Colony, New York Central and other railroads.

In 1875 the late Wm. Orton, the president of the Western Union Telegraph Company, offered Mr. Pope a position in charge of the patent interests of his company, an office which he had previously occupied with the Gold and Stock Telegraph Company. This he accepted, and for years the whole patent system of this great company was in his exclusive care.

In 1881 he engaged in private practice as patent expert and solicitor, the firm at one time being Pope, Edgecomb & Terry.

In 1884 he assumed editorial charge of the monthly *Electrician*, the title of which was shortly afterwards changed to the *Electrician and Electrical Engineer*, which position he filled until the spring of 1890.

Latterly, and up to the time of his death, he was in charge of the electrical department of the *Engineering Magazine*, which through his discriminating judgment more than to any other one factor gave to that magazine an appreciated standing among the electrical fraternity.

While not a prolific writer, his style was terse and perspicuous, and everything that he wrote bore the impress of authority and mature judgment. His contributions have therefore been preserved with greater care than those of many other writers, and the clearer recollection of what he did write gave the impression of greater prolificness than was perhaps true.

He was a man of strong convictions, and he had the courage of his convictions. He did not believe that Edison was entitled to the credit of the invention of the incandescent lamp, nor that Morse deserved more credit than Vaile for the invention of the electromagnetic telegraph, and he said so. His mind was a judicial one of a high order, and while he may have been mistaken in his judgment at times, his conclusions were the result of logical deductions from the premises as they appeared to him.

It was this very judicial character of mind that made him at once a reliable, but in one sense an unsuccessful expert before the courts. When as an expert he swore to tell the truth, the whole truth and nothing but the truth, he proceeded to do it regardless of whether the whole truth injured his client's case or not. For this reason he was not always considered the best expert to employ.

It may be said with entire truth that he never prostituted the high office of expert to selfish or improper purposes, and therefore stood as a type of all that was good and honorable in professional ethics.

Mr. Pope was a charter member of the American Institute of Electrical Engineers, and during the year 1886-7 became its president, succeeding Dr. Norvin Green, the first president of the Institute, who held the office from 1884 to 1886.

He leaves a widow, two daughters and a son, all of whom have the sincerest sympathy of the entire electrical fraternity, who realize in Mr. Pope's almost tragic death a personal loss.

The funeral took place at Great Barrington, Mass., on Wednesday, October 16, the services being held at his late residence, the old family homestead, in which Mr. Pope was born and where he met his death.

The attendance was very large, and included a number of electricians from various parts of the country, some of whom came considerable distances to pay respect to the mortal remains of him whom in life they had admired so much.

The casket, a simple black draped one, with nickel trimmings, was placed in one of the parlors.

The floral offerings were few and simple, and consisted of a broken column at the head and a wreath of autumn oak leaves at the foot of the casket, with a few cut flowers.

The room in which the remains reposed was reserved for his professional friends who later acted as honorary pallbearers.

The service was the impressive one of the Episcopal Church. After the services at the house, the honorary pallbearers formed two lines between which the casket was carried to the hearse. They then preceded the hearse on foot to the cemetery, where they again formed two lines between which the body was carried to the grave.

A simple ceremony, and all that was mortal of Franklin Leonard Pope was consigned to the earth.

How the Accident Probably Occurred.

Mr. Ralph W. Pope, Secretary of the American Institute of Electrical Engineers and oldest surviving brother of the late Franklin Leonard Pope, who was killed by electricity at his Great Barrington home on Sunday last, returned to New York on Friday.

Mr. Pope, like his brother, has had a long and varied electrical experience, and from the time of his arrival at Great Barrington on Monday up to his departure on Thursday made a daily study of every condition existing at the spot where his brother died. He also carefully questioned every person who had any knowledge of the facts, as no official examination was made beyond the autopsy on Wednesday. Mr. Pope places great confidence in the careful examination of the converters, wires, etc., personally conducted by Edward Weston, Wm. Stanley and Geo. A. Hamilton, than whom he says no higher authority could be desired. These gentlemen have a report in preparation which will soon be published.

Mr. Pope's story of the occurrence shows that his brother was apparently the victim of an accident, solely due to the fact that in order to test the lines and observe the working of the plant he had permitted the location in his cellar of a converter, which necessitated the leading in of the primary wires of the system, carrying a normal voltage of 2,100. These wires were brought in at the north cellar window at a point distant about two feet from the transformer. There was a twisted joint in each wire about midway between the entrance of the primaries and the converter to which they were connected. One of the joints stuck up, and although both were supposed to be covered with so-called insulating tape, it is quite possible that one of the points of these joints was bare, owing to the difficulty of covering such a joint unless extreme care is used. The tape from these joints had been removed after the accident and the wire adjacent to the joints themselves broken on one side and cut with pliers on the other. The joints were taken out and were found on the floor behind the cold air box on Thursday. One of the facts which an early examination did not account for was that the main scar on the right hand gave evidence of a mechanical injury, being a deep ragged scratch, as well as a scar from the electrical burn. The point of either of these joints was well calculated to produce such an injury. Two other minor burns, one on the knuckle and one on the back tip of the forefinger, might have been made either before or after the more serious injury.

As he approached the transformer with the lighted lamp in his left hand to look at the wires, it is possible that he first encountered a strong draft from the open cellar window, the sash of which was suspended by hinges, but according to the statement of Mr. Bell, who was familiar with the cellar, had been unfastened for some time and would therefore swing more or less with the wind. It was necessary in order to secure it to push the window back and at the same time turn the button on the end of the sash with his right hand. Having thus closed the window, the withdrawal of the hand apparently brought it into contact with one of the twisted joints already described, by which his body was placed in the primary circuit, the current entering his hand, passing through his body and entering the concrete floor through the soles of his shoes. It is quite likely that the flame of the kerosene lamp may have been blown out before Mr. Pope had closed the window, in which case the liability to an accident of this kind was increased; or some trivial incident may have distracted his attention for a moment.

It was a rainy day and he had walked to and from church, a distance of about half a mile, and had also strolled about his yard, so that his shoes were doubtless damp. The wet branches of trees swayed by the wind had also caused grounds on the main line through the village, the consequent flashing having been quite generally noticed that evening. Had he stood closely enough to the window to close and fasten it, he must have stood on a portion of the concrete floor dampened by the dripping of water from the wires which had no "water-drip" outside.

Mr. Weston is of the opinion that the position of the hand after closing the window was at such an angle with the wire that the existing burn could not have been made by the point, although no other theory as to the raggedness of the injury has been advanced. It is evident that no attempt was made to handle the wires in any manner, all the burns being on the back of the hand.

Tribute of the Brooklyn Electrical Society.

At a meeting of the Brooklyn Electrical Society, held in the Edison Assembly Rooms, Brooklyn, on the 15th inst., the following preamble and resolutions were adopted:

THE POPE HOMESTEAD, GREAT BARRINGTON, MASS.

Whereas, The members of the Brooklyn Electrical Society have heard with profound regret of the removal from our midst of our worthy and esteemed co-laborer in the scientific field, Franklin Leonard Pope, and

Whereas, The intimate relations held by him with the science of electricity during his life makes it fitting that we record our appreciation of him; therefore be it

Resolved, That the wisdom and ability which he has exercised in aid of the advancement of the science of electricity by counsel, service and research, will be held in grateful remembrance.

Resolved, That the sudden removal of such a man from our profession leaves a vacancy and shadow that will be deeply realized by all members of the electrical fraternity, and his name will ever remain as that of a martyr to the science in which he met his death.

Resolved, That with deep sympathy with the afflicted relatives and friends of the deceased, we express an earnest hope that even so great a bereavement may be over-ruled for their highest good.

A copy of the resolutions was sent to Mrs. Pope.

Magnetism and Eggs.

Dr. Bertram Windle, a London experimentalist, has recently made investigations of the effect of magnetism on the hatching of eggs. He found that the eggs of silk-worms, when placed in the field of a strong magnet, were apparently unaffected by the lines of force penetrating them, but hens' eggs thus treated were found to produce an unusual number of abnormal chicks. Dr. Windle submitted the eggs of trout to an electrical current traversing the water, and found it to arrest their development.

New York Electrical Society.

The next meeting of the New York Electrical Society will be held at Columbia College on Monday evening, October 28th, when Mr. P. B. Delany will lecture on "High Speed Commercial Telegraphy."

THE MONTREAL MEETING.

FOURTEENTH ANNUAL CONVENTION OF THE AMERICAN STREET RAILWAY ASSOCIATION.

The Proceedings in Detail—A Large Attendance—St. Louis the next Meeting Place.

The fourteenth annual meeting of the American Street Railway Association convened in the Windsor Concert Hall, Montreal, Canada, October 15, with President Joel Hurt, of Atlanta, in the chair.

The delegates were officially welcomed to the city in brief addresses by the Hon. J. A. Villeneuve, Mayor of the city, and by Col. A. A. Stevenson, of the Montreal Railway Company, to which President Hurt responded in well chosen words.

Next in order was the delivery of the annual address by President Hurt, as follows:

Gentlemen of the Association: You are for the first time assembled in convention beyond the confines of the States, and by this meeting on Canadian soil the lesson is taught that the Association is endeavoring to extend and receive the benefits of fraternal intercourse and broad educational work.

In this most beautiful city, situated in a profusion of nature's gifts to man, an examination and contemplation of all that may be interesting would render your limited stay most enjoyable indeed. We hope you will enjoy your visit to the city of Montreal, where you are now in convention in response to that noble fraternal spirit characteristic of the members of this Association throughout its entire field of operations, and which I am proud to say is so marked in our brethren in Montreal. Let us not forget, however, that we meet also for practical, useful work and that you are at this convention confronted with grave questions to be determined.

Before referring to matters which are in order, and which should engage your special attention, I feel constrained to speak in commemoration of the papers presented at the last annual meeting, and to invite your attention to them. I refer especially to the paper on "Uniform System of Railway Accounts" by Mr. H. I. Bettis; the paper on "City and Suburban Electric Railways" by Mr. E. C. Foster, and the paper on "Mail, Express and Freight Service on Street Railway Cars" by Mr. Richard McCulloch. While all the papers read bear evidence of much thought and merit, the three mentioned will be found especially useful.

The street railway problem of to-day is growing in importance more rapidly and is attracting to a study of its solution a greater number of educated men than any other branch of industrial work.

But a few years have sufficed to transform a business of dull drudgery and routine, in which animal power was resorted to chiefly, into a business in which the mysterious power electricity, but by a distinguished scientist denominated "God's vicegerent" (should not this be regent?) works a man's bidding on all sections of an immense system with instantaneous promptness. The usefulness of this subtle force is only equalled by the charm of its contemplation, and the ablest men of the day give homage to a business which invokes its application.

There are in operation to-day in the United States about 179,300 miles of steam roads and about 13,500 miles of street railways. The passenger receipts on the steam roads the past year were $276,031,000. The gross receipts of street railways in the United States were between $125,000,000 and $140,000,000. The street railway mileage is about 7½ per cent. of the steam railway mileage, and passenger receipts of street railways about 45 per cent. of the passenger receipts of steam roads. The total capitalization, bonds and stocks of steam roads in the United States is about $11,000,000,000, and of the street railways about $1,300,000,000. The latter is about 11 per cent. of the former, while the profits of the steam roads were $322,000,000, and of the street railways about $43,000,000, the latter being about 13½ per cent. of the former. From these figures an idea may be gathered of the magnitude of the business.

The Association having referred to the Executive Committee the question of the advisability of enlarging the scope of its work, the question will come back for your consideration with the committee's recommendations.

There are many questions which call for more extended and complete work. There are new branches of business to be cultivated by the companies, such as the handling of freight and mail, the delivery of small parcels from retail stores through a system of express, the handling of building material to suburban localities, the handling of milk on special cars for the purpose, and the operation of funeral cars from any portion of the system into cemeteries where special facilities are provided.

The companies will need to lend a mutual aid to each other through the National Association for the purpose of defeating hostile legislation in National, State and municipal governments, and to conduct a work all along the line which will tend to implant in the minds of the patrons of the roads the fundamental idea that the public interest demands friendly legislation for transportation companies, since this will tend to enable the companies to furnish the best and most rapid transportation, while harmful legislation will tend to bring about the opposite result.

The relation of street railroads to steam roads is growing more interesting, and in some localities even perplexing, until the question is now being asked, what will be the solution of the extension of electric lines which are cutting so rapidly into the business of the steam roads. A partial consideration of this question brings forth the inquiry—will not the interests of these two systems of transportation force an amalgamation of the systems, having thereby the main lines connecting distant points, which will be operated into sections at convenient points in municipalities from which passengers will be transported over various street railway lines to their destination?

The steam roads of the country are organized, the territory being subdivided into several sections for the purpose of promoting harmony and mutual protection. While it is true that street railroads do not now come into competition with each other, except to a limited extent, yet it is a question if their interests do not demand an organization with sufficient strength and facilities to keep a constant watch over the business throughout the country. It is believed that the time has come when a larger revenue must be raised, either upon the assessment plan or by increasing the membership dues.

The great and important question before you here is the one to enlarge the scope of the Association. The Executive Committee has held three long sessions, two in this city and one in New York, the time being devoted chiefly to a consideration of this question. Seven days and nights have been spent in these meetings, the results of which will appear in the committee's report, and to which your attention is invited.

I take this occasion to thank the members of the Association, especially those of the Executive Committee, for the support and co-operation extended to the officers of the Association.

After the minutes of the last meeting had been approved, the report of the Treasurer was read and showed the following result:

Receipts	$7,554.57
Expenses	7,240.55
Balance on hand	**$314.02**

After lunch the first business was the reading of a paper by Mr. E. J. Wessels on "Air Brakes," which was well discussed.

Following this a discussion on street paving was introduced by Mr. John A. Seely, who said:

I would like to inquire of the members of the Association their experience regarding street paving. I will state our case specifically: In building a railroad in a certain city the railroad company is compelled to pave its strip, 18 feet in width, with the same material that the city officials pave the remaining portion of the street, which happens in this case to be asphalt. In paving this street the paving contractor refused to do the paving unless we entirely suspended our service, taking all cars off. They paved one piece, and after that was done the railroad company decided it would not give up the street. The paving company has refused now to pave that portion of the street, claiming that it could not be done while the cars were in operation, and especially that the concrete would not set with the cars running over the rails. The railroad company has commenced to put in the concrete itself, keeping the cars moving at the same time. I am pleased to say that it is quite successful so far—the concrete being laid, headers and stretchers being put in, and cars moving right along. Of course it is expensive. The next problem is who will pave the top of the concrete with asphaltum. The railroad company is thinking seriously of constructing a plant of its own, and I would like to know if any of the gentlemen present have given up the street, given up their entire service, to the paving company to pave a street.

Mr. Johnston, of Richmond—In the work under my charge in Philadelphia I have done a great many miles of street paving, but we do it under contract. In that city they require you to pave the whole street, not your strip; if the street is 100 feet wide you have got to pave it. Our bills amount to a good many hundreds of thousands of dollars. In no case have we given up the street to the contractor. It is a piece of utter contrariness on the part of any contractor who says that he cannot lay the paving without stopping the cars. We put a concrete paving in and alongside the rail; we did $600,000 worth of this work. I did the paving in New Orleans, Philadelphia and Richmond. In Richmond we are going to put in a track laid on concrete, and do not propose to stop one minute for anything. It can be done.

Mr. Seely—Are you connected with the paving company?

Mr. Johnston—No, I am a railroad man. I will say further that some years ago I was assistant city engineer in Richmond and had charge of the paving. That was my work, and the contractors did it there for the railroad companies and the cars never stopped running a minute. There is no reason in the world why they should.

Mr. McCulloch—We pave between our rails and one foot outside, and between double tracks, with the same material with which the street is paved. We are now on one of our roads engaged in just the work the gentleman has referred to. We have two very busy streets, one of them originally paved with asphalt and the other paved with granite, both underlaid with concrete, and the men at this minute are working on both streets, and the asphalt men are paving, the concrete men are paving and the granite men are paving, and our cars are in constant operation without any hindrance or suggestion of interference, no contractor or paver ever having asked us to discontinue the running of the cars. It would not be tolerated by the Board of City Works in our city. It is not necessary, and is unreasonable on the part of a contractor, and in our city would not be tolerated. It is done with the cars in operation, and there never has been any suggestion of anything to the contrary.

WEDNESDAY MORNING.

The Convention was called to order by President Hurt at 10:45 A. M., and went into executive session.

The first topic on the programme for discussion, "The Labor Question," was taken up, the discussion being opened by Mr. Wyman, who was followed by Gen. Jackson.

The discussion was suspended to admit of the reading of a communication from Mr. Baumhoff, of St. Louis, enclosing a paper on Transfers. Both letter and paper were read, and on motion the paper was ordered to be spread on the minutes and printed.

The discussion on the subject of Transfers was opened by Mr. Sergeant, who was followed by Messrs. Charlton, McCulloch, Jackson and Hurt.

During the session an announcement was received that several gentlemen connected with the Dublin Tramways Company were without, having come upon the invitation of the President. They were invited to take seats in the hall and participate in the discussion if they so desired.

The discussion of the labor question was then resumed, Messrs. Sergeant, Wyman, McCulloch, McClary, Charlton, Hurt, McLain and Connette taking part.

WEDNESDAY AFTERNOON.

A letter was read inviting the members to attend the performance at the French Opera Theater on Thursday evening.

Mr. Hamilton then read the report of the Executive Committee, together with the amended Constitution and By-Laws proposed by the Executive Committee.

The vital points in the Executive Committee's report were as follows:

The committee found, to its surprise, that the Association was largely in debt, its liabilities exceeding its assets by nearly $5,000. These liabilities were found to be the accumulation of several years, in which the sum of the actual expenditures and the bills contracted but not settled had exceeded the receipts. It did not appear, however, that there was any extravagance in the conduct of the Association's affairs. The receipts have merely been insufficient to take care of all the work laid out by the Association at its annual meetings. The chief criticism that the committee has to make is that the situation had not long before been faced and a course of action determined upon which would prevent the annual increase of debt.

The records and property of the Association contained in the office of the Association in Brooklyn were examined by the committee and found to be well kept and in good condition, Mr. Richardson's assistant, Miss Strickland, being in charge.

The Treasurer's report had been made up for the eleven months and fifteen days from October 15, 1894, to September 30, 1895, showing in brief the following results:

Balance, Oct. 17, 1894	$94.07	
Receipts from all sources during the period named	7,263.25	$7,357.82
Total disbursements during the period named	7,040.61	
Balance in bank Sept. 30, 1895	316.71	$7,357.32

Assets and Liabilities.

Assets:		
Unpaid dues $900, charged to profit and loss by order of Executive Committee.		
Unpaid charges for space Atlanta Convention, $114, charged to profit and loss by order of Executive Committee.		
Unpaid subscriptions to Street Railway Decisions	$10.00	
Volumes Street Railway Decisions on hand, appraised valuation	200.00	
Office furniture, appraised valuation	125 00	
Cash in bank, Sept. 30	385.71	
Deficit	4,087.33	$4,808.04
Liabilities:		
Bills for printing, etc	$3,162.00	
Reports of special committees	150.00	
Loan, W. J. Richardson	300.00	
Expenses of Executive Committee	770 38	
Office rent	125.00	
Royalties	210.00	
Miscellaneous	90.00	$4,808.04

It will be seen that among the items included in "Assets," as stated above, appears one entitled "Unpaid Dues" amounting to $900. The committee regrets to say that the utmost efforts have so far failed to bring home to the members of the Association who are responsible for this item a realization of the fact that their debts to the Association are "debts of honor," which should be discharged with a promptitude certainly as great as would be the case with debts more easily collected by process of law. The committee recommends that the Association instruct the incoming Executive Committee to make a final effort to secure payment from the following companies, and if this effort shall not prove successful within sixty days, to drop the names of such companies as shall not have paid from the list and their membership shall thereupon cease.

Name of Company.	Years in arrears.	Amount due.
Sandusky Street Railroad Company	5	$125.00
Hoosac Valley Street Railway Company	6	150.00
Central Cross Town Railroad Company	4	100.00
Central Railway Company, Peoria	3	75.00
McKeesport & Reynoldtown Pass. Ry. Co	2	50.00
Syracuse Consolidated Street Railway Co	2	50.00
Paterson Central Electric Railway Company.	2	50 00
*Second Avenue Pass. Ry. Co., Pittsburg	2	50.00
Canton-Massilon Electric Railway Co	2	50 00
Metropolitan Railroad Co., Washington	1	25.00
Citizens' Electric Railway, Light and Power Company, Mansfield.	1	25.00
Allentown & Bethlehem R. T. Co.	1	25.00
Columbia (S. C.) Elec. St. Ry., Lt. & Power Co.	1	25.00
Atlanta Traction Company	1	25.00
Miami Valley Company, Piqua, O.	1	25.00
		$900 00

*During the meeting a telegram was received that the Second Avenue Passenger Railway Company of Pittsburg had paid the arrears of dues.

This committee in further explanation of the foregoing financial statement and as summary, reports as follows:

Deficit of previous years	$4,711.37
Surplus of 1895	289.04
Total deficit	$4,422.33
Assets on hand, books, furniture, etc	335 33
Net deficit	$4,087.33
Total liabilities, October 14, 1895	$4,804.04
Cash in bank, October 14, 1895	385.71
Deficit	$4,422.33
Assets deemed good	335 00
Deficit	$4,087.33

The report contained recommendations for enlarging the scope of the Association by establishing a permanent bureau of statistics and information, and by admitting supply men as associate members. A revised constitution and by-laws, providing for these changes were submitted to the Convention. Eight new companies had joined during the year and there were ten withdrawals.

Mr. Seely moved that the report of the Executive Committee be received and spread on the minutes.

On reassembling at 4.30 P. M., the Chair accorded to Mr. Harrison the opportunity of making an explanation which he desired to make respecting his non-concurrence with the report of the majority of the Executive Committee upon some items embraced in their report. This was followed by a discussion in which Messrs. Harrison, Hamilton, Jackson, McCulloch, Thompson, Hurt, Cunningham, Wyman and Fairchild took part. Finally, on motion of Mr. Wyman, it was agreed that the report as read by the Executive Committee be spread in full on the minutes, that it be printed, and a copy thereof sent to each member of the Association, and that action thereon be deferred until the next regular meeting of the Association.

A committee of seven was appointed by the Chair to make nominations of officers for the following year, and on motion of Mr. Harrison a committee of ten was also appointed to devise ways and means for raising the deficit.

THURSDAY MORNING.

The Chair announced the following committees:

On Ways and Means: R. B. Harrison, H. M. Littell, T. H. McLain, W. Y. Soper, H. M. Watson, Charles Odell, Charles Green, E. C. Goodrich, T. C. Penington and John N. Akarman.

On Nominations: C. D. Wyman, Milwaukee; Chas. S. Sergeant, Boston; John B. McClary, Birmingham; W. J. Thompson, Camden; Edward Lusher, Montreal; John A. Seely, New York; Henry Scullin, St. Louis.

The Secretary read a letter inviting the delegates of the Association to hold the next meeting at Saratoga Springs.

Mr. McCulloch, of St. Louis—We offer the Association the hospitalities of St. Louis for the next Convention. Ten years ago you were there, and we entertained you under such disadvantageous circumstances that we feel we would like to do it over again and do it properly. We were in the midst of the only strike we ever had, and at the time you were there there was not a car running in the city. We have a good many running now, and while we do not wish to boast we will say that we are not behind the times in anything, and when you come there you will find everything with us as modern and as varied as you will find it anywhere else. We have both cable and electric cars, and we have them in as good shape and condition as we know how to put them. We will try to entertain you as hospitably as we did ten years ago, and I believe you were all satisfied with everything except our operations of our roads at that time.

The Secretary read a letter from the Chicago City Railway Company, urging Chicago as the next meeting place.

A communication was read from Mr. W. J. Hammer requesting the co-operation of the Association in the establishment of standard miles for electric construction and operation. The new Executive Committee was authorized to appoint a delegate to cooperate with the N. E. L. A. and other bodies to accomplish this object.

The Chair stated that the next matter in order was discussion of municipal ordinances. The gentlemen who were requested to open the discussion on this question were not present and no discussion was offered.

At the conclusion of the executive session, the paper by Mr. N. W. L. Brown, of Atlanta, was submitted, and ordered to be printed in the minutes.

Messrs. F. R. Greene and J. W. McNamara, the committee appointed at the Atlanta Convention to submit a plan of organization whereby the Association might officially investigate all patented articles used in street railway practice, reported favorable to such an organization.

After referring to the great benefits accruing to the steam railroad companies from the Eastern and Western organizations of their members for the same purpose, and outlining the general scope of these organizations, the committee sums up the important advantages as follows:

1. Lessening total expenses in fighting patent suits, etc. as a suit affecting one road would affect all.
2. Uniformity of action.
3. Additional safety in putting on new devices.
4. Greater facility in defending suits, etc.
5. Decrease in number of suits and claims on account of the existence of such an association.
6. Advantage in settling suits.
7. Contesting and avoiding unfair and unjust royalties.
8. Reduction of prices on all patented articles.
9. By members refusing to buy articles where suits are brought against any of its members, thus shifting suits to the manufacturer.
10. The dissemination of valuable information to its members of all matters relative to any suit, etc., in which one or more members are the interested parties.
11. Advantage of employes of street railway companies in getting valuable information and assistance on their own inventions, whether patentable or infringement of other devices, without additional cost to said railway or employe.
12. The acquiring of a full and authentic report of all devices that are commonly found in use on all street railways, such as fare registers, brakes, rail bonds and numerous other articles, giving the expiration of all such patents, opinion on the validity of the same, etc., and to be followed up by like reports from time to time, giving list and opinion of new patents and list of expired patents.
13. The acquiring of models, devices, etc., for permanent exhibition.

In conclusion, your committee desires to express two plans of carrying into effect the above scheme, and recommends that the Association adopt one of the following methods:

1. Provided the members vote to increase the scope of the Association, we recommend that a bureau be established to handle all matters pertaining to patents as outlined in this report.

2. Provided it is not deemed best to enlarge the scope of the Association at this time, we recommend that the Association pass a resolution providing: That the annual dues be divided into two classes, Regular and Special (or if necessary the by-laws be amended to that effect); that all members be required to pay the regular dues as already provided in the by-laws, and that it be optional with members to pay the additional or special dues; that members paying special dues will be entitled to all the benefits to be derived through the agency of a Patent Bureau to be established under the direct control of the American Street Railway Association. That the special dues be based upon the gross earnings of the several roads; that the Association elect a Board of Control consisting of three members, whose terms shall expire in one, two and three years respectively, and hereafter electing one member each year; said Board of Control to establish and carry on a Patent Bureau as outlined in this paper, with the funds paid into the A. S. R. A. as "Special dues." Provided further, that no street railway company be entitled to the benefits and privileges of said Patent Bureau, except they are regular members of the A. S. R. A.

Respectfully submitted.

F. R. GREENE, } Committee.
J. W. MCNAMARA, }

Mr. Seely offered the following resolution:

Whereas, It is the purpose of the National Electric Light Association to hold in New York City next spring, at its annual convention, a comprehensive exhibit of modern electrical inventions and applications depending on the use of central station and power house current, with the object of increasing popular interest in electric lighting and allied arts, and

Whereas, It is the desire of the American Street Railway Association to promote on the part of the public, particularly in all large cities, a fuller and more intelligent appreciation of the great benefits that accrue from electric light, heat, locomotion and other modern triumphs of civilization,

Resolved, That this Association hereby expresses its cordial sympathy with and approval of this plan for the furtherance of electrical development, and for the enlargement of the sphere within which electricity is to perform its beneficent work.

Mr. Davis, Williamsport—I desire to say a few words in regard to the resolution just read. The National Electric Light Association intends to hold an exhibition in connection with its next annual meeting, to be held in New York City in May or June of next year. The exhibition will be held under the auspices of the National Electric Light Association, but is to be given in the name of a company formed specially for that purpose, with a sufficient capital to make the exhibit of far more than ordinary interest. I understand that the object is to include in that exposition electrical appliances applicable to street railways as well as appliances applicable to the electric lighting business. The resolution is simply intended to interest the members of this Association in that exhibition.

The resolution was then adopted.

THURSDAY AFTERNOON.

Vice-President Cunningham called the meeting to order at 2:20 P. M.

The report of the Committee on Ways and Means was presented by the chairman, Mr. Harrison, recommending the following changes:

CONSTITUTION.—*Members.*

Article III of the constitution shall be amended so as to read as follows:

Section 1.—There shall be two classes of members—active and associate.

Section 2.—Active members shall be American Street Railway Companies, or lessees, or individual owners of street railways, and each member shall be entitled to one vote by a delegate presenting credentials.

Section 3.—Associate members shall be individuals or firms, or companies, not embraced in Section 2, who have been recommended by an active member. Associate members shall not be entitled to vote.

BY-LAWS.—*Meetings.*

Article VII shall be amended by the substitution of the word "Tuesday" for "Wednesday," and by the addition of the following words to the first sentence, namely: "and shall continue four days."

Mr. Harrison stated further that voluntary subscriptions had been canvassed, and in the space of an hour and a half nearly $2,000 had been subscribed.

After an extended discussion, on motion of Mr. Goff, of Fall River, the report of the committee was *laid* on the table by a vote of 37 to 11.

Voluntary subscriptions to cancel all debts of the Association were then announced, as follows:

Mr. Robert McCulloch, St. Louis:	
Union Depot Railroad Co., St. Louis	$100
Lindell Railway Co., St. Louis	100
Missouri Railroad Co., St. Louis	100
St. Louis Railroad Co , St. Louis	100
Citizens' Railroad Co., St. Louis	100
Southern Railroad Co., St. Louis	100
Cass Avenue & Fair Grounds Railway Co., St. Louis.	100
Chicago City Railway Co	100
Covington & Cincinnati Street Railway Co	100
Camden, Gloucester & Woodbury Street Railway Co	100
Atlanta Consolidated Street Railroad Co	100
Lock Haven Street Railroad Co., Lock Haven, Conn	100
Williamsport Passenger Railway Co	100
West End Railroad Co., Boston	100
Twin City Railroad Co., St. Paul	100
Twin City Railroad Co., Minneapolis	100
Wilkes-Barre & Wyoming Valley Traction Co	100
Reading Traction Co	100
Cleveland City Railway Co	100
Louisville City Railroad Co	100
Lehigh Traction Co., Hazleton, Pa	100
North Chicago City Railway Co	100
Bridgeport Traction Co	50
Newark & South Orange Railroad Co	50
New Brunswick Traction Co	50
Winchester Avenue Railway Co., New Haven	50
Manchester Street Railway Co	50
Montreal Street Railway Co	50
Ottawa Electric Railway Co	50
Columbus Street Railway Co	50
Brooklyn City & Newtown Railroad Co	50
Consolidated Street Railway Co., Worcester	50
Citizens' Street Railroad Co., Indianapolis	50
Buffalo Railway Co	50
Hartford Street Railway Co	50
Union Railway Co., Providence	50
Terra Haute Electric Railway Co	50
Troy City Railway Co	50
Globe Street Railway Co., Fall River	50
Omaha Street Railway Co	50
Paterson Railway Co	50
Scranton Traction Co	50
Toronto Railway Co	50
Taunton Street Railway Co	25
New Haven Street Railway Co	25
St. Joseph & Benton Harbor Electric Railway and Light Co	25
Akron Street Railway Co	25
Wayne & Fifth Street Railway Co., Detroit	25
Consumers' Electric Light & Street Railway Co., Tampa, Fla	25
Des Moines City Railway Co	25
Total	$3,425

The following additional subscriptions were also made:

St. Louis railroad companies, first named	$100
Union Depot Railroad Co., St. Louis	100
Chicago City Railway Co	100
Twin City Railway Co., St. Paul	100
Twin City Railway Co., Minneapolis	100
Camden, Gloucester & Woodbury	50
Montreal Street Railway Co	50
Atlanta Consolidated Street Railroad Co	50
St. Louis Railroad Co	50
Milwaukee Street Railway Co	50
West Chicago Street Railroad Co	50
H. M. Littell	100
J. A. Bailey	100
J. Willard Morgan	25
New Bedford Street Railway Co	25
Total.	$1,050

Total subscriptions, $4,475.

Mr. Thompson moved that the Secretary be instructed to give every company an opportunity to add to this fund.

The Nominating Committee presented the following recommendations for officers for the ensuing year:

For President—H. M. Littell, Brooklyn, N. Y.

First Vice-President—Granville C. Cunningham, Montreal.

Second Vice-President—William H. Jackson, Nashville, Tenn.

Third Vice-President—J. Willard Morgan, Camden, N. J.

Secretary and Treasurer—T. C. Pennington, Chicago, Ill.

Executive Committee—Joel Hurt, Atlanta, Ga.; Prentiss Cummings, Boston, Mass.; C. G. Goodrich, St. Paul, Minn.; A. Markel, Hazleton, Pa.; W. P. Kelly, Columbus, O.

The above ticket was declared elected. and St. Louis chosen as the next meeting place.

The next business was the report of the Committee on the Use of Salt and Sand on Street Railway Tracks.

Votes of thanks were offered to the President, Vice-Presidents, and the members of the Executive Committee for the able manner in which they had discharged their official duties, and to Mr. E. E. Higgins, who had so efficiently acted as Secretary during the Convention; also to the citizens of Montreal.

FRIDAY MORNING.

The President called the meeting to order at 11 o'clock, and stated that the regular order of business called for an executive session.

Mr. Scullin, of St. Louis, moved that the session be declared an open one.

The President announced the subject of "Furnishing Free Music and other Entertainment by Street Railway Companies to the Public" to be in order.

The Chair appointed Messrs. Hamilton and Harrison a committee to escort the newly elected President and Secretary to the platform.

They were duly installed and acknowledged their election with thanks, pledging their best efforts in the development of the Association.

The meeting then adjourned, to meet in St. Louis the third Tuesday in October, 1896.

P. S.—Mr. H. C. Lewis has wired that he will remove the billiard tables from the spacious lobby of the Southern Hotel at the time of the St. Louis gathering, opening all available space to exhibitors free of charge.

The New President.

Harvey Mitchell Littell, the newly elected President of the American Street Railway Association, was born in Corydon, Harrison County, Indiana, in 1856.

Harvey Mitchell Littell.

In early life he moved to Louisville, Ky., attended the public schools in that city and embarked in the street railway business as a clerk in the office of the Louisville City Railway Company about 1874, the president at that time being C. G. Davidson, now of Brooklyn, N. Y., and H. H. Littell, his brother, superintendent. He filled various positions, as clerk in the office, starter, timekeeper, track foreman and almost every position known to the street railway business.

He afterwards entered the steam railroad business with the Louisville and Nashville Railroad Company. He worked himself up in the steam railroad business until he reached the position of general freight and passenger agent of what is now known as the Chicago, St. Paul and Kansas City Railroad Company. In the interim, however, he filled the position of general manager of the St. Paul City Railway Company for a period of three years, from 1883 to 1885, during which time he superintended the reconstruction and extension of the horse railroad system in that city, covering a territory of thirty miles of road. The road then changed hands and he accepted the position of general freight and passenger agent with the Chicago, St. Paul and Kansas City Railroad Company.

In 1888 he left the steam railroad business to take charge of the Cincinnati Incline Plane Railway, which road was changed from horse to electricity under his administration in the years 1888-1889. He remained here until January, 1893, when he was made president of the New Orleans City and Lake Railroad Company and Crescent City Railroad Company, and general manager of the New Orleans Traction Company, at New Orleans, La. These lines embraced about 120 miles of horse railroad, the changing of which to electric lines he superintended. completing the same in June, 1895.

On July 1, 1895, he was made the president and general manager of the Atlantic Avenue Railroad Company of Brooklyn, which position he now holds.

Upon his retirement from the control of the New Orleans roads he was presented by the directors of the company with a solid silver dinner service as a testimonial of their appreciation of his "character and ability as a railroad manager in the development of the property."

Mr. Littell married Miss Prawl, of Lexington, Ky., in 1882, and has two sons. He now resides with his family in Brooklyn.

SHORT STORIES OF THE CONVENTION.

Mr. W. J. Johnston, with his accustomed enterprise, published a daily bulletin which was highly appreciated by every one.

The feature of the entire week was the concert in the rooms of the J. G. Brill Company, conducted by Mr. Frank Randall. Admission was free, but exit was very expensive.

The Safety Insulated Wire & Cable Company had an active representative in Mr. H. T. Richards, whose newspaper experience has taught him the art of hustling to good advantage.

Among the exhibitors at the Victoria Rink were the following:

Consolidated Car Fender Co., Providence, R. I.
Keller Printing Co., New York.
Consolidated Car Heating Co., Albany.
Standard Underground Cable Co.
New York Car Wheel Works.
New Haven Car Register Co.
Canada Switch and Spring Co., Montreal.
Taunton Locomotive Works, Taunton, Mass.
Taylor Electric Truck Co., Troy.
Charles Scott Spring Co., Philadelphia, Pa.
Sterling Supply Manufacturing Co., New York.
Peckham Motor Truck and Wheel Co., New York.
Mica Insulator Co., New York.
Chapman Valve Co., Indian Orchard, Mass.
J. A. Roebling's Sons Co., Trenton, N. J.
Standard Paint Co., New York.
Akron Insulator and Marble Co., Akron, O.
Fiberite Co., Mechanicsville, N. Y.
Walker Manufacturing Co., Cleveland.
General Electric Co., New York.
Ohio Brass Co., Mansfield.
Hogan Boiler Co., Middletown, N. Y.
Fuel Economizer Co., Matteawan, N. Y.
Goubert Manufacturing Co., New York.
Babcock & Wilcox Co., New York.
Interior Conduit and Insulation Co., New York.
The Okonite Co., New York.

Messrs. W. B. Cleveland and J. W. Atkinson, of the Forest City Electrical Works, Cleveland, met with flattering success in their exhibition of roll-drop bars, etc., and carried away several good orders.

Messrs. Hathaway, Ackerman, Donohue and Carroll were the representatives of the American Electrical Works, and shouted the merits of a new rail bond just being introduced.

Messrs. J. W. Godfrey and Frank Harrington were industrious in looking after the interests of Habirshaw wire, the former exhibiting an interesting photograph of the company's new salesman in Japan.

Medbery insulating material was tastefully exhibited at the Rink, the booth being in charge of Messrs. H. J. Medbery and W. R. Mason.

Col. Meier, of the Heine Safety Boiler Company, was one of the busiest men at the Convention.

The Western delegation came in three hours ahead of time, under the personal supervision of Wabash Railway officials. The New York and Philadelphia delegations split up into two parties—one going over the New York Central route through the Adirondacks, the other going and returning via the D. & H. road. For the former party, Mr. M. C. Roach was the accomplished cicerone, and the arrangements for the latter were admirably carried out by Mr. William Heulings.

Mr. J. H. Rhotehamel, of the Columbia Lamp Company, improved his opportunities on the return trip by taking an order for lamps at Saranac.

The interests of Standard underground cable were carefully looked after by that Convention veteran, George L. Wiley.

The Sperry brake was the chief attraction in the General Electric Company's exhibit—if we except the punch-bowl.

Mr. Frank S. De Ronde, of the Standard Paint Company, had one of the most attractive exhibits, the samples of tape, etc., distributed by him and his friends being so popular that it was difficult to retain any on his tables.

Mr. P. M. McLaren, the rotund agent of the Abendroth & Root Company, may be expected to appear in Broadway very soon wearing an overwhelming sealskin cap, which he received at Montreal as the result of an election bet made seven years ago with a Canadian friend.

We violate no confidence in stating that no journal distributed at the meeting was the subject of so much favorable comment as ELECTRICITY.

The Duke of Gloucester was a prominent figure in the Windsor lobby, and appeared to take as much interest in the Convention proceedings as he used to when the "skates" were running at his race-track.

Mr. H. H. Harrison, of the firm of Corey & Harrison, found many appreciative listeners to his newest story.

The reception at McGill University should have been better attended, and would have been if the Association had not spent so much time in discussion of a subject which had really been settled in advance.

Mr. J. H. Carson, of the Sterling Supply Company, with his associates, had a good audience when explaining the merits of their goods at the Rink.

From the number of churches in evidence it was difficult to see how there could be any wickedness in Montreal.

Capt. Willard L. Candee talked okonite and Manson tape—as he always does—with the oratorical ability born of serene confidence in the goods he sells.

The hunt breakfast tendered by Mr. M. J. Forget was a thoroughly enjoyable affair, but few of the delegates availed themselves of the invitation. The horses used at fox hunts are not the harmless breed which street railway men are accustomed to.

From a gastronomic point of view, the banquet on Thursday evening was a thorough success. But it must be confessed that the best thing to be said of the toasts and responses is that they were not much worse than those at Atlanta. Even Joe Stedman and Charles Price were not in their usual good humor.

It was quite a common remark that the representatives of the General Electric Company were all good fellows.

The Westinghouse delegation was made up of the following gentlemen: Geo. H. Lewars, Albert Schmid, E. L. Sanderson, A. J. Craigin, B. F. Stewart, R. S. Brown, C. A. Bragg, J. A. Rutherford, E. H. Gordon, and E. H. Heinrichs.

ATTENDANTS.

Street Railway Companies Represented.

Akron, O.—W. D. Chapman, gen. supt. Akron St. RR. Co.
Atlanta, Ga.—Joel Hurt, pres. Atlanta Cons. St. RR Co.
Baltimore, Md.—S. B. Thompson, master mechanic City & Suburban Ry.
Birmingham, Ala.—J. B. McClary, supt. Birmingham Ry. & Elec. Co.
Boston, Mass.—D. F. Longstreet, ex-president A. S. R. A.; Chas. S. Sergeant, gen. man. West End St. Ry. Co.; Arthur E. Childs, Electric Storage Battery Co.
Bridgeport, Conn.—N. H. Heft, pres., Andrew Radel, gen. supt., C. J. Field, con. eng., and Henry Selzer, Jr., Bridgeport Traction Co.
Brockton, Mass.—Horace B. Rogers, gen. man., and John P. Morse, Brockton St. Ry. Co.
Brooklyn, N. Y.—H. M. Littell, pres. Atlantic Ave. RR. Co.; Duncan B. Cannon, sec. Brooklyn City & N. RR. Co.

THE THOMSON-HOUSTON REGULATOR PATENT.

A Statement of the Case.

The final decision of the United States Circuit Court of Appeals for the Seventh Circuit, in the suit of the Thomson-Houston Electric Company vs. the Western Electric Company and Enos M. Barton, concludes one of the most important patent causes relating to electrical inventions.

In 1879 Elihu Thomson and Edwin J. Houston applied for a patent upon an automatic adjuster for commutator brushes of magneto-electric machines. In this patent the applicants described and claimed a device for automatically adjusting the brushes upon the commutators of dynamo-electric machines, "whereby an automatic adaptation to variations of circuit resistance is secured." This device consisted of a relay adapted to bring into service a motor which shifted the brushes upon the commutator. The relay received its current from an accessory brush placed in advance of the main brush upon the commutator of the dynamo-electric machine.

The patentees of this "first" patent, which was issued as No. 223,659, July 20, 1880, both of them, testified that up to the time of the taking out of this patent they had not made the invention of current regulation and did not appreciate that the brushes upon the commutator of a dynamo-electric machine could be shifted so as to keep the current constant. Whether this is so or not, the fact remains that it was known to electrical engineers of that date that shifting the brushes upon the commutator of a dynamo-electric machine could be so performed as to keep the current flowing in the circuit constant, notwithstanding the variations of the resistance in the circuit. Weston testified that he had manually shifted the brushes for this purpose from 1876.

It was not long after the issue of this patent, No. 223,659, that Thomson and Houston discovered their failure to cover the device broadly for automatic current regulation. A second application upon substantially the same apparatus was therefore filed, and this patent, called generally the "second patent," had broad claims upon automatic brush-shifting current regulation. It was this second patent, No. 238,315, upon which suit was brought against the Citizens' Electric Light Company of Boston, users of Wood arc-lighting apparatus. A decision was secured in this suit in August, 1888, sustaining the validity of patent 238,315, and finding the defendants, users of the Wood regulator, to be infringers. Suit was subsequently begun against the Western Electric Company in the United States Circuit Court for the Northern District of Illinois, and after years had been spent in collecting evidence, the case came to hearing in June, 1894, before Judge Grosscup, who rendered an opinion adverse to the patent early in the present year. From this decision of Judge Grosscup the Thomson-Houston Electric Company appealed to the Circuit Court of Appeals. The case was elaborately argued in June of the present year. and the Circuit Court of Appeals has just handed down its opinion, affirming the decision of Judge Grosscup. The statement of facts occupies some forty large pages of the opinion of the Court of Appeals and comprises voluminous extracts from the testimony of Mr. Charles E. Scribner, the main witness for the Western Electric Company and one whom the Court of Appeals describes as an expert of conceded intelligence, skill and accuracy.

In addition to the defence which was most strongly urged, namely, that of the first Thomson-Houston patent, No. 223,659, which showed substantially the same device as that of the later patent, No. 238,315, upon which suit was brought, the invention of Maxim of an automatic current regulator for dynamo-electric machines which was applied to separately excited dynamos running incandescent lamps in multiple arc, was urged as an anticipation of the patent in suit, and it will be observed from the opinion of the court that this defence also was considered to be adequate to defeat the broad claim of Thomson and Houston for automatic brush-shifting current-regulation.

The Western Electric Company, who defended this case at the expenditure of much time and money, is to be commended for its pluck and intelligence. At the beginning of this litigation, after the decision by Judge Colt sustaining the patent, the outlook for a successful defence was fuliginous in the extreme. The competitors of the Thomson-Houston Electric Company, some of whom were courageous in undertaking patent litigation, almost unanimously preferred to surrender and sell out to the Thomson-Houston Electric Company, or to go out of the electric lighting business, rather than undertake the defence of this suit. The Western Electric Company in conducting this defence, therefore, had to contend not only with the prior decision in favor of the patent, but also with the almost universal acquiescence of the public in the claims of this patent, which claims have now been authoritatively found to be, as the Western Electric Company all along was convinced, unjust and inequitable.

American Institute of Electrical Engineers.

The 100th meeting of the Institute will be held on Wednesday, October 23, 8 P. M., at 12 West 31st street, New York City, having been postponed from October 16 by direction of the president.

A paper will be presented by Mr. Hermann Lemp, Jr., of Lynn, Mass., on the "Local Annealing of Hard Faced Armor Plates."

A paper will also be presented by Professor W. M. Stine, of Chicago, on "The Rating and Behavior of Fuse Wires."

A meeting of Western members will be held the same evening, Wednesday, October 23, 8 P. M., in the rooms of the Western Society of Engineers, 1737 Monadnock Building, Chicago.

Applications have been received from the following candidates for associate membership and will be acted upon by council at its meeting November 20, 1895: Ellicott Maccoun, Munhall, Pa.; Alfred K. Warren, New York City; Paul G. Burton, New York City; Eugene Friedlaender, Duquesne, Pa.; Chas. L. Brown, Chicago, Ill.; Erich Rathenau; Berlin, Germany; Eskill Berg, Schenectady, N. Y.; Henry Storrs Webb, South Bethlehem, Pa.; Clarence P. Gott, New York City; Fred'k Wm. Phisterer, Ithaca, N. Y.; Nevil Monroe Hopkins, Washington, D. C.; Wm. D. Ball, Chicago, Ill.; Clinton C. Burr, Pittsburg, Pa.

Should a member object to the election of any of the above candidates, he should notify the secretary to that effect prior to November 20.

The council will hold its regular monthly meeting in the rooms of the Institute, 26 Cortlandt street, Wednesday, October 23, 4 P. M.

The Welsbach Burner.

Some months ago ELECTRICITY took up the question of the Welsbach burners as competitors with electricity, and showed that for most purposes the much-vaunted burners had defects that would, in the long run, cause them to be laid aside. One of the most striking instances of this was shown in the case of the public schools at Vienna, where at first they were received with delight, but after trial were ordered out. That seems to be the general experience, and we notice place after place in San Francisco where one month you will see the sickly green rays of the Welsbach and a few months later they are gone. The *Electrical Engineer* in a recent number appears however to be somewhat muddled over the subject. It prints a lot of one-sided statements from *Progressive Age*, a gas organ, in which great claims are made for the Welsbach especially for use in stores. The *Engineer* then says: "What have electric light men to say to this? Our own comment on the situation appears on page 257."

All the *Engineer* says on page 257 is to the effect that the Welsbach burners will probably not prove suitable for *street lighting*. We would advise the *Engineer* either to investigate the matter a little, or to read up the back files of its contemporary, ELECTRICITY, before it throws up its hands in this style. —*Pacific Electrician*.

A NEW BATTERY ELEMENT.*

NOTE BY M. MORISOT, PRESENTED BY M. LIPPMAN.

I have the honor to introduce to the notice of the Academy a new battery element, which seems to me an important one on account of its electromotive force, which is greater than that of the usual couples, and also its current, which is practically constant.

This element is composed in the following manner:

1. The positive pole is a plate of retort carbon, immersed in the outer vessel in the depolarizing liquid. This is composed of one part of sulphuric acid, mixed with three parts of water, previously saturated when cold with bichromate of potash. Some crystals of this salt are held suspended in the upper part of the liquid in a short funnel.
2. A porous cell, immersed in the depolarized liquid, contains a weak solution of caustic soda (density = about 1.05).
3. The plate of amalgamated zinc, which is the negative pole, is immersed, within a second porous cell placed inside the first one in a concentrated solution of caustic soda (density = about 1.25). This latter solution, suggested by M. Reynier in 1880, for the Daniell battery, raises the electromotive force of the same from 1.1 volts to about 1.6 volts.

The electromotive force of this element is 2.5 volts at the beginning; it afterwards keeps above 2.4 volts during at least 10 hours of uninterrupted action.

The internal resistance is about .8 ohm; it varies, moreover, with the thickness and the structure of the porous cells.

In the experiments that I made, the quantities employed were:

For the depolarizing liquid, 600 cubic centimeters.

For the diluted solution of soda, 130 cubic centimeters.

For the concentrated solution, 110 cubic centimeters.

Under these conditions the current was maintained very near the following values:

For a resistance of 5 ohms interposed .423 ampere.
" " 10 " " .22 "

It therefore remained practically constant in both cases, notwithstanding the difference in the output. If the circuit is closed immediately after the setting up of the element, the resistance is at first greater, and consequently the current is less. The regular rate of working is established nearly an hour later, when the porous pots are sufficiently soaked. We obtain the definite rate of working at once if we do not close the circuit until after the soaking is complete.

It is the substitution of the alkaline solution for the acidulated water containing the zinc in the Poggendorff battery that raises the electromotive force from 2.1 to 2.5 volts. In fact the same substitution made in the Bunsen battery gives 2.25 volts instead of 1.85 volts, *i.e.*, the same increase, viz., .4 of a volt.

But if we confine ourselves to this change only, the advantage soon becomes deceptive, on account of the rapid increase of the resistance. The soda changes into neutral chromate, and we find on the zinc and round it an abundant deposit of hydrate of oxide of zinc. These actions, due to the modification of the liquids by one another through the pores of the porous pot, are considerably reduced, and their effect weakened by the interposition of the alkaline liquid contained between the two porous cells. This addition does not greatly increase the resistance, and it has the advantage of ensuring an almost absolute constancy, especially if we partly renew the weak solution of soda from time to time. This renewal is, moreover, necessary, as the level is soon seen to fall between the two porous cells. A good result is obtained by drawing off through a tube, about every three hours, a little of this intervening liquid which has become colored, and restoring the level by means of fresh weak soda; I used 40 cubic centimeters for each renewal.

The employment of potash instead of soda offers no advantage, any more than the employment of bichromate of soda instead of bichromate of potash in the depolarizing liquid.

I found that the zinc is much less attacked than in the Poggendorff element, and all those in which the metal is immersed in acidulated water. In this case the consumption of zinc is partly replaced by the consumption of soda. If there was an equal consumption of zinc, we should have an electromotive force of 3.1 volts; in fact, a normal couple, the zinc of which is replaced by a carbon, and in which the liquids act alone, gives 1 volt at the commencement.

After 10 hours of continuous action, we find the zinc covered with a gray crust. We can restore its polish and its original qualities by withdrawing it from the battery and immersing it, for a few moments only, in some acidulated water, which quickly dissolves this crust. The reconstituted element, even if the liquids are not changed or partially renewed' then resumes its action almost as at the commencement. We see that in this way the liquids could be used again for some time.

Lastly, I noticed that if the battery is to work for two or three hours only, for demonstration experiments, for instance, we can dispense with the amalgamation of the zinc.

PROF. PUPIN'S ASSOCIATION PAPERS.

The Most General Relation Between Electric and Magnetic Force and Their Respective Displacements.*

The author states the fundamental relations and hypotheses of Maxwell's Electromagnetic Theory. He points out the failure of the theory to explain dispersion and absorption of light and the rotation of the plane of polarization. He next points out that in all successful attempts so far to bring these phenomena within the scope of the electromagnetic theory, Maxwell's fundamental relation between electric and magnetic force and their respective displacements is abandoned, and in its place hypothetical relations are assumed, which are justified by the circumstance only that they lead to results which are in agreement with experiments. The author shows then that the relation between the electric and the magnetic force and their respective displacements, which Maxwell employed in his theory, is not the only permissible one.

In fact, the relation employed by Maxwell is a *statical* one, and is, therefore, a limited case of a more general one which may be called the kinetic relation, which the author obtains by considering the electromagnetic field in which the forces are varying in any continuous manner whatever.

This kinetic relation may be expressed as follows:

$$\int d\tau \int_0^t \left[\left(X\frac{df}{dt} - f\frac{dX}{dt}\right) + \left(Y\frac{dg}{dt} - g\frac{dY}{dt}\right) - \left(Z\frac{dh}{dt} - h\frac{dZ}{dt}\right)\right] dt \geqq 0.$$

In this formula X, Y, Z are components of the electric or of magnetic force at any point.

f, g, h are the components of the electric or of magnetic displacement at any point.

$d\tau$ is an infinitely small element of volume of the field.

dt is an infinitely small element of time.

The integration should extend over the whole electromagnetic field and from the moment of starting the field up to the time t when the field becomes constant.

The author shows that this kinetic relation contains Maxwell's relation as a special case and that it also contains those relations between the electric and the magnetic force and their respective displacements which were hypothetically assumed in all successful attempts to explain, by the electromagnetic theory the phenomena of dispersion and absorption of light, and the rotation of the plane of polarization.

Flow of Alternating Current in an Electrical Cable.*

The author discusses the problem in its most general aspect, showing how transmitting or receiving apparatus at any point of the cable should be taken account of by the theory. The application of Lagrange's generalized equations of motion to this problem is pointed out.

The theory of transmission of telephonic currents over long lines is then discussed as a special case, and it is shown that the initial value of the current at the sending end depends on the electromagnetic constants of the transmitter and is practically independent of the electromagnetic constants of the line. The wave length and the attenuation of the waves, on the other hand, depend entirely on the electromagnetic constants of the line.

Experiments with an artificial cable are then described and the experimental results compared with the theory showing the agreement between the two.

Several conclusions bearing on long-distance transmission of power, long-distance telephony and submarine telegraphy; the bearing of magnetic hysteresis on the attenuation of waves along cables containing iron wire is finally considered in the discussion of artificially loaded cables.

Married.

Mr. C. F. Scott, of the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa., was married on Tuesday, 15th inst., to Miss Clarke, of Columbus, O. ELECTRICITY extends hearty congratulations to Mr. and Mrs. Scott, and wishes them a happy and prosperous career.

---

* *L'Industrie Electrique.*

*Abstracts of papers read by M. I. Pupin, Adjunct Professor in Mechanics, Columbia College, New York, at the meeting of the American Association for the Advancement of Science, Springfield, Mass.

GENERAL NEWS.

What is Going on in the Electrical World.

Springfield, O.—The city clerk has been instructed to advertise for bids for 150 arc lights of 2,000 C. P. each, for city lighting.

Titusville, Pa.—Leading citizens of this city have petitioned the councils urging the building of an electric street railway.

Grand Rapids, Mich.—A movement has been started here for an electric line to connect this city with Rockford. It is regarded as a feasible scheme.

Fergus Falls, Minn.—Burns & Howard, of Minneapolis, have been awarded the contract for the new municipal electric light plant; price, $12,900.

San Francisco, Cal.—The Sutro Electric Railway, which is the third line running to the ocean beach, is completed and cars will begin running at once.

Kalamazoo, Mich.—H. C. Hoagland, of Elmira, N.Y., has been appointed superintendent of the municipal lighting plant and much is hoped from his management.

Morgantown, N. C.—The plant and franchises of the Morgantown Electric Light and Power Company have been sold to Geo. O. Baker and W. G. Baker of New York.

Pittston, Pa.—The charter of the Pittston, Jenkins and Avoca Street Railway Company has been filed and it is proposed to construct an electric road from Moosic to Pittston.

Riverside, Ill.—The trustees of this village have granted a franchise to the Suburban Electric Railway Company, of which D. B. Lyman, of La Grange, is president.

South Orange, N. J.—The South Orange and Maplewood electric railway is completed and in operation. On the trial trip a speed of thirty-nine miles an hour was attained.

Waverly, Ia.—J. N. Bowman, president of the First National Bank, is interested in the company to be incorporated to construct an electric road between Cedar Falls and Waverly.

Hempstead, N. Y.—The Hempstead Gas Light Company has been awarded the contract for lighting the village with seventy 800 C. P. arc lights, the contract to begin January 1 next.

New Haven, Conn.—Vice-president Hall of the Consolidated road has stated that the Stamford and New Canaan branch, about eight miles in length, will be equipped with electricity.

Bath, N. Y.—There is talk of an electric road from this village to connect with the Troy and Sand Lake road at Wynantskill. A direct route would make the distance less than five miles.

Madison, Ind.—The council has passed a resolution instructing the committee on light to advertise for lighting the city with electricity for a term of fifteen years at a specified price per lamp per year.

New Philadelphia, Ohio.—The commissioners of Tuscarawas County have advertised for proposals for the franchise for the construction of an electric railway between New Philadelphia and the twin cities.

North Tonawanda, N. Y.—Frank W. Hawley is here frequently nowadays looking over the work of constructing the lines for the canal trolley test, which he asserts will take place within the next two weeks.

Oswego, N. Y.—The directors and stockholders of the Oswego Street Railway have decided to increase their capital stock from $75,000 to $200,000. The object of the increase is to enable the road to issue $75,000 more bonds.

West Chester, Pa.—A meeting of the capitalists interested in the construction of an electric railway from West Chester to Quarryville, Lancaster County, will shortly be held and the company will be formally organized.

Meadville, Pa.—The electric street railway bill, making the franchise good for thirty-five years and requiring three per cent of gross receipts after ten years, has passed the councils. Two companies are after the franchise.

Norwalk, O.—H. K. Beck of Norwalk and J. W. Stoakes of Milan have been elected directors of the Sandusky, Milan and Norwalk Railway to fill the vacancies caused by the resignations of W. H. Price and C. H. Stewart.

Amsterdam, N. Y.—It is understood that the Amsterdam electric street railroad has been sold to the Amsterdam, Johnstown and Gloversville Railroad Company, but the purchasers will not take possession of the plant until spring.

Knoxville, Tenn.—Chairman Reps Jones of the board of public works has signed the contract with the Knoxville Electric Light Company for lighting the city. The company will put in $30,000 worth of improvements and begin work at once.

Homestead, Pa.—The Carnegie Steel Company has bought the electric light plant on Ninth avenue. The plant was owned by the Edison General Electric Company. The Carnegie company will operate it and furnish light to the borough.

Richfield Springs, N. Y.—At the recent corporation election held here, the candidates favoring the introduction of an electric railway were elected by an overwhelming majority. The old officials were opposed to the admission of an electric road into the town.

Summit, N. J.—The newly elected officers of the Mountain Electric Light Company are: President, John N. May; treasurer, William Halls, Jr.; secretary and general manager, C. P. Bassett; executive committee: Norman Schultz, John May and C. P. Bassett.

Hackensack, N. J.—The commissioners have been authorized by the council to advertise for bids for lighting the town with electricity or gas for terms of one and three years, the electric light bids to be for incandescent and arc lights. The present contract expires in November.

Weldon, N. C.—The citizens of Ringwood are making an effort to build a trolley line from that point to Littleton, via Brinkleyville, Medoc and Panacea Springs. The road would pass right through the tobacco belt, and the hauling of tobacco, cotton and wine from Medoc would give it a big business.

New Berlin, Conn.—The power house of the Electric Light Company was totally destroyed by fire on the 8th inst. The loss was estimated at about $15,000, as none of the dynamos or other machinery could be saved. The plant was a comparatively new one, having been in operation but two or three years.

Painesville, O.—The commissioners have granted a franchise to the Cleveland, Painesville & Eastern Street Railroad Company over county highways from the west line of Lake county to the west line of Painesville village. The road must be completed and operated by electricity within one year.

Little Falls, N. Y.—The council has granted a franchise to the Little Falls Electric Street Railroad Company to run an electric railroad through the principal streets of this city. President Tyler of the company intends to apply for a franchise to enter Richfield Springs, and if it is granted will extend the road to that village.

Corry, Pa.—The Corry Electric Street Railway has been organized with the following officers: President, R. N. Seaver; secretary, C. P. Rogers, Jr.; treasurer, D. L. Bracken; directors, R. N. Seaver, R. P. Dawson, D. L. Bracken, T. A. Edwards, H. L. Gordon, Frank Laurie and F. A. Beebe. The company is capitalized at $18,000.

Allegan, Mich.—F. A. Makin, the promoter and general manager of the Saugatuck, Holland and Southeastern Electric Railway, says the line will surely be built. The contract for the rails has already been let to the Illinois Steel Company of Chicago. E. J. Harrington is president of the road, but the capitalists who are to put their money into the scheme are not known.

Edgartown, Mass.—A committee of citizens has issued a circular stating that for an outlay of $45,000 the electric street railway can be extended from Cottage City to Edgartown. Stock subscriptions from permanent and summer residents to assist in securing the proposed extension are solicited. The committee consists of Edward W. Chadwick, Joseph W. Donaldson and Charles W. Marchant.

Easton, Pa.—The Easton Power Company has been granted a franchise by the South Easton council to establish an electric lighting plant in that town. It is the intention of the company to erect works for the manufacture of dynamos, motors, rheostats and all other kinds of electrical instruments. They propose to furnish light for the borough, stores, private residences, etc., in connection with the manufacturing plant. The company's superintendents are Lewis F. Johnson and Walter Slacke.

Paterson, N. J.—The stockholders of the New Jersey Electric Railway have elected the following directors: Thomas D. Jordan, James A. Morrisse, Francis C. Van Dyk, Charles Currie, John L. Heins, William H. McIntyre and George V. Turner. John L. Heins, who is also superintendent of the Brooklyn City and Newtown Railroad Company, has been elected president. Mr. Heins is regarded as one of the most capable railroad men in Brooklyn.

Hagerstown, Md.—The city council has granted a franchise to the Hagerstown and Potomac Electric Railway Company to build a street railway in Hagerstown and extensions to Williamsport, Funkstown, and Leitersburg, Md., and Waynesboro and Pen-Mar, Pa. The road will be built by Pennsylvania capitalists. John W. Bears, Harrisburg; Judge William Grier, New Bloomfield, and Frederick L. Snyder, Altoona, will be three of the seven incorporators.

Middletown, Conn.—The Schuyler Electric Factory was sold by public auction on the 15th inst. to the General Electric Company for $73,000, and all patents and patents applied for belonging to the Schuyler Company were sold to the General Electric for $40,000. They also bought the balance of the machinery not included in the first two lots for $8,250. President Boyd says he will try to lease the Schuyler plant from the General Electric Company.

Sioux City, Iowa.—The arrangements for the consolidation of the Sioux City Cable Railroad, the Sioux City and Leeds Electric Railway, the Sioux City Elevated Railway and the City and Suburban Railway companies and their sale to a New York syndicate have been completed. The roads will be merged into one system and connected with the South Sioux City Electric Railway, which will cross the new Pacific Short Line bridge and extend several miles into Nebraska.

East Pittsburg, Pa.—The Westinghouse Electric and Manufacturing Company have begun the erection of a foundry and machine shop as additions to their already immense plant here. The new departments, which will employ 300 additional workmen, are to be completed by January.—The entire board of directors of the Pennsylvania Railroad Company made a careful inspection of the Westinghouse Electric and Manufacturing Company's works and railway apparatus at East Pittsburg last week.

Langhorne, Pa.—A new company, to be known as the Langhorne, Bristol and Newtown Trolley Company, has recently been formed here and has obtained its charter. Work on the road will begin at once on that portion lying within this town and in the spring the line will be continued to Bristol. At the latter place the line will connect with the proposed Philadelphia and New York trolley line. In time the route will no doubt be extended in the other direction as far as Doylestown.

Boston, Mass.—The "Herald" says: "There is every prospect of great additions to the mileage of electric street railways around Salem and vicinity. The Lynn and Boston Company has fully determined to equip and run the Old Salem and Danvers road with electricity, and also to extend its electric power from Gloucester crossing in Beverly to Wenham. It is thought that this latter work will be begun at once and prosecuted so that electrics will be running this winter. This is believed to mean the extension from Wenham-Hamilton to Ipswich in the spring."

Philadelphia.—President J. Lowber Welsh has announced the names of the executive committee which is practically to have managerial control of the 400 miles or more comprising the consolidated street railway system in this city. The committee are George D. Widener and Thomas Dolan, of the Philadelphia Traction Company; J. J. Sullivan and Alfred Smith, of the Electric Traction, and Caleb F. Fox and W. H. Shelmerdine, of the People's Traction. President Welsh, as ex-officio member, will be the chairman of the committee. The latter will direct all the working movements of the system, will revise the service, suggesting improvements and economies.

St. Louis.—J. D. Houseman, the projector of the Houseman Air Line, otherwise known as the Baumhoff electric line, to Meramac Highlands, now announces that he will build another and longer road in St. Louis County. This will be a branch of the air line and will start from the power house at Brentwood. It will go westward over a private right of way between the Manchester and Clayton roads, past Mentor, Rock Hill, Des Peres, Manchester, Baldwin, Ellesville, Melrose and other important points to Pacific, Mo., a distance of nearly 40 miles. Mr. Houseman has decided to generate the necessary electricity from a water supply on the banks of the Meramac, just west of Pacific.

Kansas City, Kan.—The Argentine Water and Electric Light Works have been sold here under a decree of the United States Circuit Court, to satisfy a judgment in favor of the Farmers' Loan and Trust Company of New York. The property was bid in for the bondholders' committee, composed of Theodore C. Woodbury of Portland, Me., Julius Hammerslaugh of New York city, and Robert McLay, president of the Knickerbocker Trust Company of New York. The price paid was $40,000; the judgment was for $150,000 and interest. The operation of the works will continue under the direction of the reorganization committee.

Hartford, Conn.—President Clark of the New York, New Haven & Hartford Railroad, in his annual report, referring to the change from steam to electricity on the Nantasket Beach Railroad, says: "The experiment has demonstrated that power generated in a stationary plant and transmitted by electrical agency can be successfully used in the operation of a standard railroad. The current expenses for fuel indicate that this result is economically obtained. Power thus transmitted is capable of indefinite subdivision, and is therefore most available for frequent car service. The commercial result depends only on the durability of electrical equipment. It is probable that electricity will be promptly adopted by the company at other points."

Baltimore, Md.—It is stated that a franchise will be soon applied for to build an electric street railway over a number of streets which were included in the "Ram's Horn" franchise. The Central Railway Company, of which George Blakistone is president, is alleged to be an applicant for the franchise.—Mr. Clemens Hershel is examining the plans of the Susquehanna River Electric Company for the hydraulic work of the proposed generating plant at Conowingo on the Susquehanna River, and will pass upon them as soon as possible. It is fully expected that the construction of the plant will be commenced before the close of the present year. About 40,000 horse-power is the amount of power attainable, and it is proposed to transmit this by means of electricity to Baltimore and other places.

Asbury Park, N. J.—The Atlantic Coast Electric Railway Company has arranged to lease the Asbury Park and Belmar Street Railway Company. The former corporation owns the extensive Asbury Park system and also the new line from this place to Pleasure Bay. The Belmar road runs as far south as Shark River, and will soon be extended through Belmar, Como, North Spring Lake, Spring Lake, Sea Girt and Manasquan, where it will meet the electric road at Point Pleasant. The Atlantic Coast Company is controlled by the Metropolitan Traction Company of New York City, and expects to soon extend its lines from the seashore to Trenton. The trolley roads between Eatontown and Red Bank and Red Bank and Atlantic Highlands will soon be completed, when the entire shore from New York Bay to Barnegat Bay will be skirted by an electric road.

Columbus, O.—Another electric light company has been granted a franchise to establish a plant in this city, but the franchise must be ratified by a vote of the citizens.—A resolution has been adopted by the council to advertise for bids for lighting the streets of the city.—Attorney General Richards, in answering the question of the State Commissioner of Railroads and Telegraphs as to whether electric or trolley railroads operating outside of cities and towns and carrying freight as well as passengers are subject to the laws governing railroads generally and come under the commissioner's authority, says: "In my opinion you have authority to inspect the railroads you describe, notwithstanding the fact they are operated by electricity. Such railways cannot properly be classed as street railways, but, transporting passengers, freight and express between different parts of the State, they are railroads or railways within the proper acceptation of the term, although operated by electricity."

Pittsburg, Pa.—The stockholders of the Citizens' Traction Company have voted to lease the lines of the company to the Fort Pitt Traction Company for 950 years beginning November 1 next. The lease covers all the property and franchises of the Citizens' Passenger Railway Company, a part of the line of the Transverse Passenger Railway Company, the line of the Penn Street Railway Company, the line of the Aspinwall Street Railway Company and the charter of the Highlands and Butler Street Railway Company, no part of which is built. The Fort Pitt Company assumes the obligations of the Citizens' Company and pays an annual rental of $180,000. It is agreed that the Fort Pitt shall, prior to November 1, 1897, reconstruct so much of the Citizens' lines as is now operated by cable, and equip it with the most improved electric system. This applies also to the lines to be built.

Salt Lake City, Utah.—James A. Kelman, secretary of the Salt Lake and Ogden Gas and Electric Light Company, told a reporter of the "Tribune" a few days ago that his company was controlled by a wealthy London syndicate whose intention it was to make the Salt Lake plant the foremost in America. "By our co-operation with the Big Cottonwood Power Company," he said, "we have made it a certainty that cheap electrical current will be delivered into this city, and we have commenced to remodel our system of wires in the commercial district of the city in order to be ready to connect with the Big Cottonwood when it gets here. We will put in new dynamos here within a few weeks, and with our new system we will be able to run arc and incandescent lights and motors from the same wire. We will introduce the newest incandescent lamps, and these will be furnished free of cost to the present patrons of he company." The Citizens' Electric Company has ust entered the field as a competitor of Mr. Kelman's ompany.

Cleveland, O.—The county commissioners have granted he Wadsworth Electric Railway Company a franchise to onstruct and operate an electric railway from Brooklyn o the south line of Cuyahoga county. Under the terms f agreement the road will be completed within a year. The road, when completed, will extend from Brooklyn o Medina, the county seat of Medina county, and hence to Wooster, in Wayne county. The road has permission to transport light freight and United States mail. The franchise is for twenty-five years. James L. Mauldin and George D. Hile are the promoters of the enterprise.—C. Crosby Thompson, manager of the Cuyahoga Suburban Electric Railroad Company, says that it s the intention to have the new line to Chagrin Falls in operation before winter weather sets in. The company does not intend to stop at Chagrin Falls, but some time within the next year or two may extend its lines to Buron, Mesopotamia and other places which are greatly in need of good transportation facilities. The company's State charter allows mail and express matter, baggage nd farm produce in boxes and barrels to be carried.

PERSONAL.

Mr. E. E. Cary has resigned his position as superintendent of the Beacon Lamp Company, Boston.

Convention of Electrical Workers.

The next Convention of the National Brotherhood of Electrical Workers will be held in Washington, D. C., from November 11 to 17. The programme will include visits to the White House, the Capitol, Congressional Library and other places of interest in the city. One night will be devoted to an electric street parade of which a complete electric plant, including engine and dynamo, will form an interesting part. The session will be concluded by a banquet to be given by the members of Local Union No. 26, of Washington City, to the visiting members.

Engraved "Sunbeam" Lamps.

A novel feature in incandescent lamp manufacturing has been introduced by the Sunbeam Incandescent Lamp Company, of Chicago, who have recently perfected a process for engraving lamps and can now furnish lamps with any special design that is desired, such as a wreath of flowers, likenesses of individuals or cuts of buildings. This company has already fitted up several stores in Chicago with these ornamental lamps, which are being received with great favor.

James G. Biddle, Drexel Building, Philadelphia, sales agent of the Weston Electrical Instrument Company, has issued an elaborate catalogue and price list of the products of this well known firm. The book comprises thirty-two pages profusely illustrated and contains much information for those unskilled in the use of measuring instruments.

INCORPORATIONS.

The Eastport Lighting Company, Eastport, Maine—to make and distribute gas and electricity for light, heat and power and mechanical purposes. Capital stock, $50,000. Promoters: W. A. Carey, Malden, Mass.; Walter Campbell, Henry H. Wardsworth, Eastport.

The Lafayette Machine Electric Light and Power Company, Lafayette, Col.—to furnish electricity for light and power both for mining and manufacturing. Capital stock, $100,000. Incorporators: J. S. Spencer, F. D. Taggart and J. H. Mayham. The company has been lighting Lafayette for about a year and now proposes to extend its operations.

The capital stock of the Laporte Electric Company, Laporte, Ind., has been increased from $25,000 to $40,000.

The Waterloo and Cedar Falls Rapid Transit Company, Waterloo, Iowa—to construct and operate electric street car lines in Waterloo and Cedar Falls, and between the two cities. Capital stock, $600,000. Incorporators: C. J. Fosselman and J.H. Bowman, of Waverly; L. S. Case, of Sumner, and J. H. Rafferty, of Waterloo.

The Lafayette Engineering and Electric Works, Lafayette, Ind.—to manufacture and sell electrical and steam machinery, engage in manufacture and sale of articles of all kinds manufactured from wood and metal. Capital stock, $60,000. Promoters: Chas. B. Robertson, Henry T. Meigs, John G. Flathers, Edgar V. Burt, Samuel Moore, Lafayette, Ind.

The Block Plant Electric Light Company, Boston, Mass.—to install, operate and maintain electric light plants. Capital stock, $15,000. Promoters: Thomas C. Fitzgerald, Henry Krey, David S. Boyder.

The Joliet Light, Heat and Power Company, Joliet, Ill.—to construct, maintain and operate gas and electric heat, light and power plants. Capital stock, $100,000. Promoters: J. E. Sutherland, L. J. Highland, John S. Ward.

The Automatic Battery Company, Louisville, Ky.—to manufacture, purchase and sell electrical batteries and other medical appliances and remedies. Capital stock, $5,000. Promoters: W. Neb. Webb, John Tierney, Warfield Webb, Louisville, Ky.

The Merchants' Electric Light Association, Lafayette, Ind.—to manufacture, supply and sell electric lights in Lafayette, Ind. Capital stock, $3,000. Promoters: P. A. Byers, F. B. Sheppard, Henry Rosenthal, C. H. Ankeny, Chas. E. Rugers' Sons Co., The Hogan-Johnson Co., Arthur A. Jeffries & Co.

The Garrett Water Company, Garrett, Ind.—to furnish Garrett with wholesome water and electric light for public use, etc. Capital stock, $20,000. Promoters: S. L. Fryer, J. A. Clevenger, Wilbert H. Hershberger.

The Suburban Electric Light and Power Company, East Orange, N. J.—to produce and furnish electric light and power, etc. Capital stock, $200,000. Promoters: Wm. H. Allen, S. Walton Freeman, Jerome D. Gedney, East Orange, N. J.

The Medway Electric Light and Power Company, Medway, Mass.—to manufacture and sell electricity for light, heat and power. Capital stock, $10,000. Promoters: E. Cutler Wilson, Henry E. Bullard, Clarke P. Harding, John D. Shippee, Daniel S. Woodman.

The Dayton, Springfield and Urbana Electric Railway Company, Springfield, Ohio—to construct and operate an electric railway from Dayton through Springfield to Urbana; manufacture and sell electricity for light, heat and power, etc. Capital stock, $10,000. Promoters: Fred. Colburn, John C. Webb, J. S. Harshman, Wm. H. Hanford, H. T. Mathers.

The Enclosed Carbon Lamp Company, Ironton, Ohio—to manufacture, buy and sell all kinds of electrical machinery, appliances and supplies. Capital stock, $50,000. Promoters: J. R. Cook, E. W. Bixby, C. H. Moore, J. W. Slater, Lester Keller.

The Owosso & Corunna Electric Street Railway Company, Owosso, Mich.—to construct, own and maintain a street railway, etc. Capital stock, $50,000. Promoters: James H. Edmunds, Cape May, N. J.; Irene D. K. Ralph, Lancaster, Pa.; Willis R. Armstrong, Philadelphia, Pa.

The Martin Underground Trolley Company (incorporated in W. Va.), Chicago, Ill.—to construct, own and operate the Martin underground trolley system, etc. Capital stock, $5,000,000. Promoters: James McDavitt, Gustav Schultz, Edw. O'Donnell, Samuel P. Marsha, Chicago, Ill.

The Mahanoy Valley Street Railway Company, which will operate a line between Ashland and Gordon, Schuylkill county, Pa., has been chartered. Capital stock, $1[illegible]

The Lexington Electric Company, Kansas City, Mo. Capital stock, $80,000. Incorporators: E. R. Kimball, E. G. Taylor, C. A. Burton, E. O. Marquis and D. M. Wolfe.

The Hagerstown & Potomac Electric Railway Company Hagerstown, Md. Capital stock, $200,000. Incorporators: Dr. E. A. Wareham, Samuel H. Long, Edward Hoffman Wyatt M. Keedy, Hagerstown; William Grier, John W. Beers and Frederick L. Snyder, of Pennsylvania.

The Holton Electric Company, Holton, Kan.—to deal in electrical supplies. Capital stock, $10,000. Incorporators: Clarence A. Ross and W. H. Blood, Jr., of Kansas City; L. P. Bonebrake, of Holton.

The Marietta Terminal Railway Company, Marietta, O. Capital stock, $125,000. Incorporators: Reuben L. Nye, Theodore B. Dale, Henry C. Vincent, Wm. H. Morse and Ossner R. Vincent.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 15, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

547,783. Conduit System for Electric Railways. John Hartman, Philadelphia, Pa. Filed April 7, 1893.

547,784. Supply System for Electric Railways. John Hartman, Philadelphia, Pa. Filed Aug. 7, 1893.

547,847. Combined Electrical and Mechanical Brake. James R. Cravath, Chicago, Ill. Filed Aug. 10, 1895.

547,873. Switch or Cross-Over System for Electric Railways. Henry M. Brinkerhoff, Chicago, Ill., assignor to Carter H. Fitzhugh, same place. Filed June 13, 1895.

547,914. Series Electric Railway. Oliver B. Finn, Philadelphia, Pa. Filed March 29, 1894.

547,931. Insulator for Trolley-Wire Supports. John W. Meaker, Evanston, Ill. Filed Nov. 19, 1894.

548,011. Trolley-Wheel. Henry Schmidt, Moline, Ill. Filed Jan. 5, 1895.

548,032. Supply System for Electric Railways. Henry V. Brown, Brooklyn, N. Y. Filed Nov. 21, 1894.

548,070. Electric Railway System. John La Burt, Brooklyn, assignor, by mesne assignments, to the La Burt Electric Railway Company, New York, N. Y. Filed June 26, 1894.

548,074. Trolley Rope and Pole Controller. Charles A. Lord, San Francisco, Cal., assignor of one-half to T. A. Kirkpatrick, same place. Filed Jan. 9, 1893. Renewed Aug. 9, 1895.

ELECTRIC LIGHTS AND APPLIANCES.

547,835. Electric Car-Lighting Apparatus. William Biddle, Brooklyn, N. Y. Filed Jan. 16, 1895.

548,028. Electric-Arc Lamp. Charles Beseler, Jersey City, N. J. Filed May 4, 1895.

548,036. Incandescent Electric Lamp. Samuel E. Cox, Cleveland, Ohio, assignor to the Adams-Bagnall Electric Company, same place. Filed July 18, 1895.

548,126. Electrical Illumination. Daniel McF. Moore, New York, N. Y. Filed Oct. 13, 1894.

548,127. Electric-Lighting System. Daniel McF. Moore, East Orange, N. J. Filed July 19, 1895.

548,128. Electric-Lighting System. Daniel McF. Moore, New York, N. Y. Filed April 10, 1895.

548,129. Method of Electric Illumination. Daniel McF. Moore, New York, N. Y. Filed Dec. 4, 1894.

548,130. Regulation of Electrical Phosphorescent Illumination by Magnetic Induction. Daniel McF. Moore, New York, N. Y. Filed Jan. 3, 1895.

548,131. Apparatus for Generating Phosphorescent Electric Light. Daniel McF. Moore, New York, N. Y. Filed Jan. 7, 1895.

548,132. Phosphorescent Electrical Illumination by Oscillation. Daniel McF. Moore, New York, N. Y. Filed Jan. 9, 1895.

548,133. Phosphorescent Electric Illumination by Intermittent and Permanent Interruption in Vacuum. Daniel McF. Moore, New York, N. Y. Filed Jan. 24, 1895.

548,134. Electrical Illumination by Phosphorescent Flame. Daniel McF. Moore, New York, N. Y. Filed Jan. 25, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

547,834. Electrical Transmission of Power. William D. Baldwin, Yonkers, N. Y. Filed July 3, 1894.

547,930. Coupling for Electromotors. Franz Marburg, Jr., Buffalo, N. Y. Filed May 14, 1895.

548,038. Thermo-Electric Generator. Harry B. Cox, Hartford, Conn. Filed Jan. 31, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

547,960. Telephone System and Cable. Joseph W. Marsh, Pittsburg, Pa., assignor to the Standard Underground Cable Company of Pennsylvania. Filed May 6, 1895.

548,027. Telephone Attachment. Charles B. Bernhard, Cleveland, Ohio. Filed March 15, 1894.

SIGNALING APPARATUS.

547,897. Electrical Succession Signaling or Calling System. James G. Smith, New York, N. Y., assignor of one half to Robert G. Vassar, same place. Original application filed Jan. 14, 1895. Divided and this application filed Feb. 23, 1895.

547,942. Electrical Succession Signaling or Calling System. James G. Smith, New York, N. Y., assignor of one-half to Robert G. Vassar, same place. Filed Jan. 14, 1895.

MISCELLANEOUS.

547,820. Staff Apparatus for Working Single-Line Railways. Illius A. Timmis, London, England. Filed Dec. 1, 1893.

547,891. Apparatus for Placing Electric Cables. Edwin S. Reid, New York, N. Y., assignor to the Standard Underground Cable Company of Pennsylvania. Filed June 18, 1892.

547,979. Electric Heater. George H. Whittingham, Baltimore, Md., assignor to the Whittingham Electric Car Heating Company, same place. Filed July 15, 1895.

548,150. Electrical Gold and Silver Extractor. Alfred Williams and William R. Phillips, Seattle, Wash., assignors of one-third to Fred Everett, same place. Filed Jan. 21, 1895.

548,162. Combined Diaphragm and Electrode. James Hargreaves, Farnworth-in-Widnes, and Thomas Bird, Cressington, near Liverpool, England. Filed Dec. 31, 1894.

THE TELEPHONE WORLD.

Telephone Litigation.

The following is an abstract of the Answer of the National Telephone Manufacturing Company et al., in suit of the Bell Telephone Company for preliminary injunction:

* * * * * *

II. And further answering, these defendants upon information and belief deny that said Patent No. 463,569 in said bill declared upon is a good and valid patent ; and allege that the same is wholly invalid :

First—By reason of the delay in the Patent Office in and about the granting of the same, during which delay many rights accrued to the public in and about the invention alleged by said bill to be described and claimed in said letters patent and during which several patents involving the alleged invention issued to said Berliner, which delay, these defendants allege, being in no respect their fault, constitutes no reason why they should be prejudiced by said delayed letters patent issued on an invention alleged in said bill to have been made in 1877—eighteen years ago—rather than the complainant, who was a party to such delay, if not actively and intentionally, at any rate in fact ; that there is no reason why these defendants, or the public, should exclusively suffer for such delay, and the said applicant and his said assignees be in no degree prejudiced thereby ; that if, by reason of the fault of the law or of the Patent Office, or of the applicant or those in his interest, or of all combined, such delay occurs in the Patent Office as in the case of the patent in said bill declared upon, so that, in the meantime, applicant fully publishes the invention and other inventors perfect the invention, then, whether said delay amounts to laches upon the part of the applicant or those in his interest, or amounts to only non-compliance with the principles upon which the patent law is founded, or to failure to conform to its established conditions precedent, the patent is invalid ; and that the complainant has no equity to enjoin these defendants under said letters patent No. 463,569 ; but that the complainant is estopped to assert or enforce such patent.

Second—Because the patent No. 463,569 in said bill declared upon, and especially the alleged broad claims thereof, are for the same subject-matter, thing or invention as letters patent to said Berliner, No. 233,969, of November 2, 1880 ; and were, therefore, allowed and issued contrary to the statute in such case made and provided. These defendants allege that the structure of the apparatus is identically the same, and described to be the same, in both of said letters patent Nos. 463,569 and 233,969 ; and that the mode of operation of said apparatus is the same in each of said letters patent ; and that the said two patents are for the same invention, and for use in the same art ; and that the later of the two, viz., said patent No. 463,569, declared upon in said bill, is void.

Third—Because the thing, apparatus or mechanism described and claimed therein was not a patentable invention or discovery, but an inoperative and worthless device, wholly failing in point of utility ; and did not involve the exercise of invention, and was not novel at the time of its alleged invention, and has never been of any utility, or put to any use.

Fourth—Because the application made June 4, 1877, was not according to the statutes of the United States, and did not become in accordance therewith by the amendments up to and including July 27, 1877, and up to and including October 27, 1877, as an application for the constant-contact variable-pressure transmitter or microphone, or for an art, method or process for the transmission of speech ; and no application for such transmitter or such art or method was made until after the same had been in public use, by the complainant and others more than two years ; whereby said Berliner abandoned said alleged invention, if the same were ever made by him.

Fifth—Because the invention alleged in said bill to be described and claimed, in said patent, is substantially other than and different from any indicated, suggested or described in the alleged application therefor of June 4, 1877, or in the attempted amendments up to July 27, 1877, or up to August 8, 1877, or up to and including October 27, 1877 ; and if any application made after said June 4, 1877, was for such alleged invention, the same dates from the filing thereof and not, as an allowable amendment, from said June 4, 1877, and is subject to all usual defences thereby arising.

Sixth—Because said patent No. 463,569, so far as the same describes or broadly claims the constant-contact variable-pressure transmitter, or microphone so-called, was unjustly obtained by the said Berliner, or his assigns, for that which was, in fact, the invention of Alexander G. Bell, then of Salem, Mass., who was then using reasonable diligence in adapting and perfecting the same.

Seventh—Because said patent No. 463,569, so far as the same describes or broadly claims the constant-contact variable-pressure transmitter, or microphone so-called, was unjustly obtained by the said Berliner, or his assigns, for that which was, in fact, the invention of Thomas A. Edison, then of Menlo Park, N. J., now of Llewellyn Park, who was then using reasonable diligence in adapting and perfecting the same.

Eighth—Because said patent No. 463,569, so far as the same describes or broadly claims the constant-contact variable-pressure transmitter, or microphone so-called, was unjustly obtained by the said Berliner, or his assigns, for that which was, in fact, the invention of Elisha Gray, of Chicago, Ill., who was then using reasonable diligence in adapting and perfecting the same.

Ninth—Because said patent No. 463,569 was unjustly obtained by the said Berliner, or his assigns, for that which was, in fact, the invention of James W. McDonough, of Chicago, Ill., who was then using reasonable diligence in adapting and perfecting the same.

Tenth—Because said patent No. 463,569 was unjustly obtained by the said Berliner, or his assigns, for that which was, in fact, the invention of William L. Voelker, of Springfield Township, Delaware County, Pa., who was then using reasonable diligence in adapting and perfecting the same.

Eleventh—Because the alleged invention, the constant-contact variable-pressure transmitter, or microphone, or substantial and material parts thereof, had been patented in the United States prior to said Berliner's invention or discovery thereof, in letters patent, to

Thomas A. Edison, of August 12, 1873, No. 141,777.

Thomas A. Edison, of April 30, 1878, No. 203,016.

Thomas A. Edison, of April 30, 1878, No. 203,014.

Alexander Graham Bell, of March 7, 1876, No. 174,465.

Alexander Graham Bell, of January 30, 1877, No. 186,787; and in letters patent of Great Britain, to

Thomas A. Edison, No. 2,909, dated July 30, 1877.

Henry Hunnings, No. ——, dated September 16, 1878; and in letters patent of Canada, to

Thomas A. Edison, No. 8,026, dated October 20, 1877; and in letters patent of France, to

Thomas A. Edison, No. 121,687, of December 19, 1877; and in letters patent of Belgium, to

Thomas A. Edison, No. 43,984, of January 11, 1878; and in letters patent of Italy, to

Thomas A. Edison, No. 9,791, of January 19, 1878; and in letters patent of Spain, to

Thomas A. Edison, dated May 6, 1878; and in other letters patent the dates and numbers whereof are not now known to defendants, but which when learned they pray for leave to insert in this their answer.

Twelfth—Because the alleged invention, the variable-pressure constant-contact transmitter, or microphone, or material and substantial parts thereof, had been described prior to said Berliner's invention or discovery thereof, in the following printed publications, viz.:

(Then follows a long list of publications.)

Thirteenth—Because, before any invention by said Berliner of the alleged variable-pressure constant-contact transmitter, or microphone, the same, or substantial and material parts thereof, has been invented, and were known to and used by the following persons in this country, residents of the following places at the following places :

A. G. Bell, of and at Salem, and at Boston and Washington.

Thomas A. Edison, formerly of and at Menlo Park, New Jersey, now of Llewellyn Park, New Jersey.

Elisha Gray, of and at Chicago, Ill.;

William L. Voelker, of Springfield Township, Pa.;

Daniel Drawbaugh, of and at Eberley's Mills, Pa., and other persons whose names and residences are now unknown to these defendants, but which, when found, they ask leave to insert in this their answer.

Fourteenth—Because for more than two years prior to any application under and according to the laws of the United States, by the said Berliner, or his assigns, for letters patent for the invention alleged in said bill to be described and claimed in said letters patent No. 463,569, the same, or material and substantial parts thereof, had been in public use in this country both by this complainant and their predecessors and assignors, and by said Berliner, at said Boston and elsewhere, and by Alexander Graham Bell, of Salem, at Salem and Boston and Washington, D. C., and by Thomas A. Edison, formerly of Menlo Park, now of Llewellyn Park, New Jersey, at said Menlo Park, and by Elisha Gray, of Chicago, at said Chicago, and elsewhere; and by various other persons whose names and residences are now unknown to these defendants, but which, when found, they ask leave to insert in this their answer.

III. And further answering, defendants allege on information and belief, that before the application of June 4, 1877, alleged in said bill to have been filed by said Berliner for said letters patent No. 463,569, the invention, machine or apparatus set forth in said application, had been published in the printed publications hereinbefore in paragraph eleventh set forth; and had been also in public use in Germany by Philip Reis, aforesaid ; G. Quinke, of Heidelberg, Giesen; C. Bohm, of Aschafenberg ; Dr. R. Bottger, president of the Physical Society; Albert & Son, mechanics ; Johann Ehren, and Segismund Theodore Stein, of and at Frankfort-on-the-Main ; Leon Garnier, Ernst Hockheimer, Rudolph Meissel, Heinrich Hold and Heinrich F. Peteur, at Freidrichsdorf and in England by William Ladd, of London ; and at Dublin, Ireland, by Thomas Ballad, of Bristol, England; Stephen M. Yates and A. M. Voreker, of said Dublin; which said use had shown that the apparatus known and described, as aforesaid, as the Reis telephone, transmitted not only musical sounds, but to an extent articulate sounds and speech, which transmission defendants allege to have been in part and at times accomplished by varying the resistance in the circuit by varying the pressure of the electrodes, thereby weakening the current without breaking the circuit.

And further answering, defendants show unto your Honors that the said Berliner, at the time of the alleged invention set forth in said bill, appears to have been an uninformed and tentative experimenter upon various theories, including those enunciated by the said Bell in his said patent of 1876, but not then fully or generally understood, admitted or current even among scientific students, and does not appear by his said application, or by his acts and writings to have appreciated the alleged necessity of constant contact between the electrodes, in order to embody Bell's method of transmitting articulate speech, until long after practical forms of constant-contact variable-pressure transmitters had been produced; that he naturally failed in his application of June 4, 1877, and in his attempted amendments up to and including October, 1877, to set forth or claim an invention which he does not appear to have then arrived at, to wit, a constant-contact variable-resistance transmitter; that he had therefore, by his own admission, sought to protect himself by filing caveats for what are now considered opposite and inconsistent inventions, and after his caveat of April 14th, alleged in said bill to be for a transmitter operating by weakening the current, but which he appears to have regarded as operating by make-and-break of circuit, he filed April 30, 1877, a caveat for an air-discharge instrument, and on May 9, 1877, a caveat for a distinctly make-and-break transmitter; that his application of June 4, 1877, was never made to state the necessity of constant variable contact in conformity with the requirements of the patent law, and particularly U. S. R. S., Section 4,863, until after other inventors had produced commercial forms of constant-contact variable-resistance transmitters, or even until the same had been in public use for more than two years, as hereinbefore set forth, and that none of the apparatus produced by him has ever been of any practical use in telephony, nor the public his debtor for any advance in the art. The Blake form of carbon microphone was introduced commercially in the fall of 1878; the Edison carbon transmitters were in extensive public use in the summer of 1878, and were invented as early as April, 1877, and improved in July, 1877, as shown in applications for said Edison patents, Nos. 474,230 and 474,231. And long before that, substantially the same structure as that described in said Berliner letters patent, No. 463,569—a simple structure, as defendants believe—had been made and operated as a musical telephone and for other electrical uses, by various persons hereinbefore named.

In view of these facts and circumstances and of the history and state of the art, these defendants upon information and belief further say that the said Emile Berliner was not the inventor of any practically useful or commercial microphone, or constant-pressure variable-contact transmitter, as alleged in said bill, or as described or claimed in said letters patent No. 463,569 ; but that the same was the product of the state of the art in 1876, the invention of A. G. Bell, set forth in his letters patent of 1876 and as herein before mentioned, the invention of Elisha Gray, and others as hereinbefore set forth, supplemented by the inventions of Thomas A. Edison, upon some of which he applied for patents in April and July, 1877, as shown in United States letters patent to said Edison, Nos. 474,230 and 474,231, and hereinbefore set forth; and so far as improved by other and later inventors than said Bell and said Edison and others aforesaid, the valuable features of such variable-contact transmitter were largely devised by Blake, Hunnings, and others mentioned in complainant's bill, and are described in various patents and publications now constituting the exposition of the art of electrically transmitting speech as practised at the present time.

That in view of the history and state of the art, and of said references, the letters patent No. 463,569, declared on in said bill are not valid as a patent for an art, method or process; nor as a broad patent for the machine known as a constant-contact variable-pressure transmitter; but if valid at all, only as a patent for precise forms or details of structure merely, of narrow and limited scope.

IV. And further answering, defendants say on information and belief that the invention and improvements, alleged in said bill to be described and claimed in said letters patent No. 463,569, were patented to the said Emile Berliner, or to those in his interest, in foreign countries before the same were patented in the United States, and that patents therefor so granted in such foreign countries have expired, and that by force of the statutes of the United States in such case made and provided, the said letters patent No. 463,569 have expired and become void and of no effect, and that complainant is not entitled to any relief in equity thereon, that said foreign patents to said Berliner are:

Letters patent of France, No. 134,481, of January 8, 1880.

Letters patent of Canada, No. 11,734, to said Berliner and one Williams, of September 8, 1880, and others, the countries, dates and numbers whereof are not now known to defendants but which, when found, they crave leave to insert in this their answer.

The Watson Switch Patent Not Valid.

Commenting upon the statements recently made in the columns of ELECTRICITY in reference to the validity of the Watson telephone switch patent, the *Pacific Electrician*, of San Francisco, says:

"The patent, which has been considered one of the most valuable of the patents controlled by the American Bell Telephone Company, is not worth the paper it is written on. The device in its broadest and most complete form was invented by Mr. Paul Seiler of this city over two years before Mr. Watson applied for a patent.

"It was used commercially as early as 1878, and in the following years over 2,500 telephones were manufactured here using this switch. Telephones are in use to-day in the interior of this State that were put in in 1878. In most cases where the validity of patents has been attacked on the ground of prior use, it has been a question whether the use was not rather a laboratory experiment. In the present case this question cannot arise, for the Seiler switch, which is identical with the Watson switch, was manufactured and used on hundreds of telephones. The Bell Telephone people may as well throw up their hands so far as the Watson patent is concerned.

"It is worthy of note that Californians were the first to recognize the possibilities of the telephone, and that here in the early days of the telephone industry it reached a degree of development far in advance of any place else in the world, and this was due almost entirely to the business ability of George S. Ladd and the mechanical genius of Paul Seiler.".

Western Union's Business.

The report of the Western Union Telegraph Company for the year ending June 30 contains the following figures: Gross earnings, $22,218,019; operating expenses, $16,076,629; net earnings, $6,141,389; balance, $5,207,577; dividends, $4,767,737, and surplus, $439,844. The balance sheet stands: Accounts payable, $1,230,382; cash, $1,488,434; accounts receivable, $2,560,609; supplies, $243,483; real estate, $4,979,533; stocks and bonds owned, $8,397,520. Miles of wire, 802,651; offices, 21,360; messages sent, 58,307,715.

There was constructed during the year 817 miles of new pole line at a cost of $574,639, which, with $16,000 paid for patents, was charged to surplus account. The American Rapid Telegraph Company was absorbed through an increase of $550,000 in capital stock. There was a marked falling off in press messages, and an increase in full-rate messages.

Want the Appeal Dismissed.

When the appeal in the Berliner telephone transmitter patent case comes up before the United States Supreme Court at the present session, the attorneys for the Bell Telephone Company will move to dismiss the appeal, their contention being that by the Evarts law establishing the Circuit Courts of Appeals their decisions in cases arising under the patent laws are made final. The Government will oppose the motion on the ground that the case did not arise under the patent laws, but is a case presenting the question whether or not the United States can initiate proceedings to annul patent.

The Largest Branch Telegraph Office.

The Chicago Board of Trade is said to have the largest branch telegraph office in the world. The Western Union and Postal companies have 170 operators on the floor every day, and one company alone has been known to handle 12,000 messages in the few working hours of the Board of Trade day. This enormous telegraphic business is now being supplemented by a telephone service. Twelve instruments have been already installed, 24 are to be added shortly, and it is not unlikely that before long 100 instruments will be in use. The telephones are all on private lines, not connected in any way with the telephone exchange, but merely serving for direct communication between members on the floor and their offices.

Will Boycott Telephone Monopoly Candidates.

At the last meeting of the New York City Board of Trade and Transportation, the Committee on Telephone reported progress, and asked that all candidates in New York State be canvassed before election and sounded on their views regarding the telephone monopoly, and that only those Assemblymen and State Senators be supported or voted for who pledge themselves in favor of a measure crippling the monopoly.

The City Council of Saginaw, Mich., and the Bell Telephone Company have locked horns over the payment of a bill for the inspection of the poles of that company. Recently an ordinance was passed which provides that once each year the city shall cause all telegraph, telephone, electric light, trolley support and other poles in the city to be inspected to see that they are properly erected, painted and that the wires are properly strung on them, the fee for the inspection to be 50 cents per pole, to be paid by the company owning the pole. A bill of $550 was presented to the Bell Company. Payment was refused and the city will sue to collect it.

Morgan T. James of Youngstown, O., is organizing a company, to be composed of Youngstown and Cleveland capitalists, for the purpose of operating an independent telephone exchange in the former city. At least 400 subscribers have already been obtained on three and five year contracts at $20 and $30 per year, and an application for a franchise has been made.

The Red Hook Telephone Company, Red Hook, N. Y., has completed its lines, which will give telephone facilities to the villages of Barrytown, Barrytown Corners, Annandale, St. Stephen's College and Red Hook. The company is now constructing lines to Upper Red Hook, Madalin and Tivoli.

On the application of stockholders the office of the Indiana Telephone Construction Company, with headquarters at Frankfort, Ind., has been placed in the hands of Charles W. Fish, of Elkhart, as receiver.

The New York and New Jersey Telephone Company has applied for a franchise to lay underground conduits in Orange, N. J., agreeing to put all its wires underground if the franchise is granted.

A movement is on foot looking to the building of an independent telephone line connecting Americus, Ga., with the Plains and other towns along the Georgia and Alabama Railway.

J. T. Foley and William T. Slaughter, proprietors of the telephone system at Martinsville, Ind., have secured a franchise for a telephone exchange at Spencer, Ind.

The Saginaw Valley Mutual Telephone Company has applied for a franchise at Flint, Mich., agreeing to furnish service for $24 and $18 per year.

The Central District and Printing Telegraph Company of Pittsburg will extend its telephone service from Wheeling to Parkersburg, W. Va.

The Colorado Telephone Company will establish a new line of communication between Greeley and Denver via Brighton, Platteville and Fort Lupton.

The new telephone company organized at Chippewa Falls, Wis., has been granted a franchise in that place.

Storm Lake, Ia., is to have a new telephone company.

New Companies Incorporated.

The Eastern Ohio Telephone Company, Richmond, Ohio, has been incorporated with a capital of $5,000.

The Cairo Telephone Company, Cairo, Ill. Capital stock, $5,000. Incorporators: Thomas W. Gannon, Angus Leek and Francis J. Fitzgerald.

The Oak Telephone Company, South Haven, Mich. Capital stock, $20,000. Officers: C. J. Monroe, president; B. F. Harmon, treasurer; A. T. Dewer, secretary and manager.

A New Idea in Tape.

The Okonite Company, Ltd., always progressive and leaders in all that pertains to their special line of goods, took a new idea in tape to the Montreal Street Railway Convention, which created a genuine sensation and caused any amount of favorable comment. The novelty consists of a new form in which the company is putting out the celebrated Manson Tape, and was shown by Capt. Willard L. Candee, who was to be found here, there and everywhere surrounded by an interested group of the electrical fraternity eager to get points on the "good thing."

The usual manner of supplying the trade with tape has been for the manufacturers to put it up in half pound packages or rolls, incased in tin foil or other wrapping. It is the general experience of most companies that the linemen in using tape so put up, after taking what was needed for the work in hand from the roll, would throw what was left away, or if they did put it back into their kit, the wrapping would soon become loose, the tape gather dust and dirt and in a short time become almost unfit for further use.

Captain Candee showed the Manson Tape packed in round tin boxes of two colors—red and white—both very attractive and neat in appearance, and containing one ounce of the tape. This nine times out of ten is a sufficient quantity for any ordinary repair, and if there be any left over it may be put back into the box, which is conveniently small (about the size of a silver dollar) where it will be kept fresh and clean and ready for use at any time. The new form of packing meets an evident want and will unquestionably mean a considerable saving to the companies and prove a great convenience to linemen. The Manson Tape is furnished in two colors; the black tape will be put up in red boxes lettered in black, the white tape in white boxes also lettered in black.

Captain Candee returned from the Convention with a large number of valuable souvenirs in the shape of substantial orders for the novelty. As a large number of our readers are probably devotees of the "wheel," it is of interest to state that the tape put up in this way adapts itself perfectly to the needs of cyclists as well, and will doubtless prove as popular in that quarter as for purely electrical uses.

The "A.-B." Incandescent Lamp.

Last week there was presented to our readers cuts and description of the new arc lamp manufactured by the Adams-Bagnall Electric Company of Cleveland. This week there is presented a cut of the Incandescent Lamp manufactured by the same company. The incandescent lamp catalogue issued by this company has for its opening sentence, "Something new in incandescent lamps." This has a refreshing sound to it, but the "newness" does not consist simply in a newly figured or an odd shaped bulb, but there are really some important changes embodied in the new lamp.

The "A.-B." Lamp is constructed without the glass tip on the large end. This may seem a small matter on first thought, but further consideration will enable one to realize the important changes made. The glass tip is caused by welding a tube to the large end of the bulb and then sealing off close to the bulb when the air has been exhausted from the same. To get rid of this tip it is necessary to seal off at the other end. In order to do this it is necessary to abandon the usual glass mount. This therefore changes the entire interior construction of the bulb and the "A.-B." Lamp presents an entirely new appearance. The side of the bulb is drawn inwardly in the shape of sharp pointed projections which take the place of the usual glass mount.

The platinum wires are conducted through the walls of the bulb at diametrically opposite points, as far apart as it is possible to place them, and all trouble from short circuiting at this point is therefore avoided. A new feature in the manufacture of this lamp is the application of a small brass ferrule to the lamp during the process of construction. When the leading-in wires have been attached to the platinum they are laid along the neck of the bulb in small grooves provided for that purpose. Over these wires and the neck of the bulb is then placed the ferrule (shown in Fig. 2) which seats on the glass. The plaster or cementing substance is then placed in the open end of the ferrule, filling the grooves and depressions in the glass made for its reception. After this the bulb is exhausted and sealed off at the neck end. The lamps are placed in stock in this shape. It can be readily understood that with an open end ferrule the plaster can be better applied to the glass than with a blind end base. The plaster being applied during the process of construction has ample time to dry and harden before the lamps are shipped to market. This avoids all trouble arising from green lamps or lamps which will loosen at the base. This loosening at the base has been one of the greatest difficulties lamp manufacturers have had to contend with.

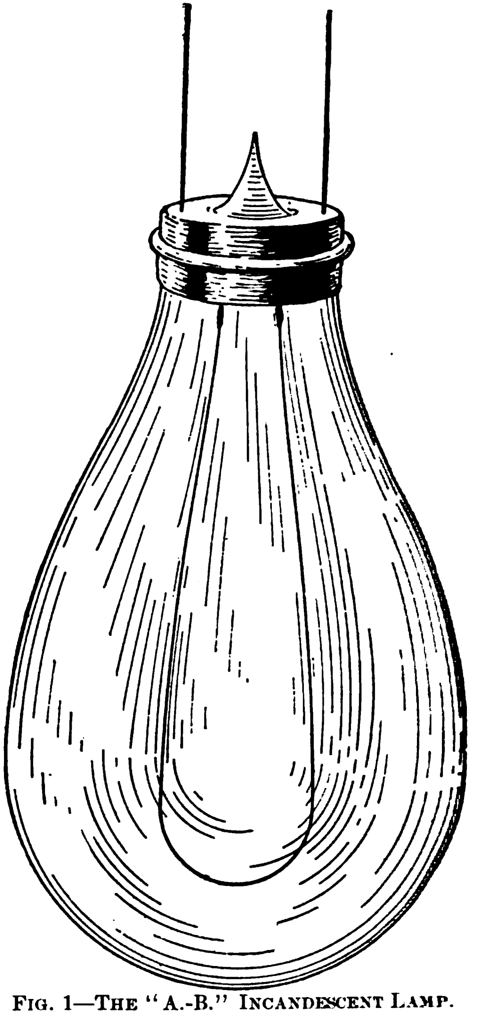

FIG. 1—THE "A.-B." INCANDESCENT LAMP.

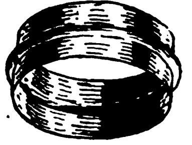

FIG. 2.

An ordinary lamp base is not constructed with a view to its being attached properly by plaster to the neck of a glass bulb. This additional brass ferrule used on the "A.-B." Lamp seems to perform an important function in the surmounting a serious difficulty in the manufacture of incandescent lamps. The fastening of the lamp base to the ferrule is accomplished by mechanical means and without loss of time in waiting for the plaster or cement to dry. Care has been taken by this company to select a very handsome shaped bulb. Besides being tasty in appearance the lamp is novel in every respect.

Patents have been awarded this month to the Adams-Bagnall Electric Company covering this lamp and its method of construction.

ELECTRICITY.

Vol. IX. NEW YORK, OCTOBER 30. 1895. No. 16

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRESIDENT.
L. J. MONTGOMERY, SECRETARY.

Publication Office, - - 6 Park Place, New York.

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

BUSINESS MANAGER, - - - JOHN L. GANS.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The Standard Telephone Company.

In the issue of ELECTRICITY for October 16 there was printed a photographic fac-simile of a circular bearing the copyrighted imprint of the Standard Telephone Company of New York, a corporation made up of men of high standing and wide reputation. The circular was one of the most remarkable documents ever issued by a business concern and included the following paragraph :

So that the promoters of a local telephone company, under a Standard Telephone Company's license, have $20 in cash net profit on each 'phone to play with a d a stock interest in every telephone of $34 TO GREASE COMMON COUNCILS, TO SELL TO LOCAL THIRD FLOOR SUBCELLAR INVESTORS, ETC. YET THE BOYS WHO ARE IN THE REAL POT, IF THEY PLAY THEIR CARDS RIGHT, will have this control of every local telephone company's plant on the above basis, annually 51 per cent. and $20 in cash. . . .

The publication of this circular has naturally created a sensation in the telephone world, and has been particularly interesting to the various gentlemen who invested money in State and local rights of the Standard Telephone Company, believing it to be a legitimate enterprise. Some of these people have been thrown into such a fright that they have rushed into print with very rash statements, which they will have great difficulty in substantiating.

At Richmond, Va., the local Standard Company is fighting for a franchise. After the publication of the circular referred to, in ELECTRICITY, the directors, Messrs. R. H. Smith, J. F. Bradley, Thos. R. Marshall, A. B. Guigon, Geo. W. Cross and John C. Robertson, made a long statement to the Common Council, the gist of which is published on our telephone page. Among other things they say :

> . . . The Standard Telephone Company has never issued any such circular as that quoted by our opponents from ELECTRICITY, a journal of unsavory reputation, which is not recognized in the electrical profession; nor has it made any suggestion of corrupt dealings with councils.
>
> The Standard Telephone Company has its own factory now in active operation in New York, and is establishing several now in the North.

It is rather difficult to see how these Richmond gentlemen can be so certain that an office in New York over which they have no control has ever issued this circular, or any other circular.

The unqualified statement that the Standard Telephone Company has a factory in operation in New York shows that these gentlemen have been imposed upon, as have many other State and local companies. After a diligent search for several months, no one, so far as we know, has found any trace of such a factory in this city or anywhere else. On the contrary, it is known that the Standard Telephone Company has had a few telephones made under contract by other companies, and only last Saturday their New York office was in the custody of the sheriff on an attachment issued for a claim of about $1,500 for such telephones sold to the Standard Company. The matter was finally adjusted.

ELECTRICITY publishes no bogus news, makes no misstatement of fact. We have never yet felt called upon to defend our reputation. We advise our Richmond friends to go slow. They talk too much on subjects of which they have no knowledge.

Gen. James S. Clarkson, whose name has been prominently connected with the Standard Company, is quoted as follows in an interview concerning this circular in the *New York Herald:*

> We never issued it and know nothing about it. We have gone into a big fight and expect a hard struggle, and this is part of it.

As soon as our attention was called to this we sent the following letter to Gen. Clarkson :

[COPY].

"ELECTRICITY,"
6 Park Place, New York. October 25, 1895.

HON. J. S CLARKSON,
Fifth Ave. Hotel, New York.

DEAR SIR: I notice in a recent interview attributed to you, in the *New York Herald*, a denial of the authenticity of a Standard Telephone circular recently published in this paper, and would esteem it a favor if you will make such denial over your own signature, and forward to me.

Yours very truly,
(Dictated.) (Signed) B. E. GREENE, Publisher.

As we go to press (October 29) no reply has been received.

A letter was also sent to Thurlow Weed Barnes, the president of the company. To this no reply has been received.

[COPY].

"ELECTRICITY,"
6 Park Place, New York. October 25, 1895.

THURLOW WEED BARNES, ESQ.,
President Standard Telephone Co., New York.

DEAR SIR: I notice that in interviews with various people connected with your company, the authenticity of one of your telephone circulars, recently published in this paper, is denied, and I beg to advise you that you are at liberty to use whatever space in our columns is necessary to deny that the circular in question was prepared and issued by the Standard Telephone Company of New York.

Yours very truly,
(Dictated.) (Signed) B. E. GREENE, Publisher.

There have been several developments in the affairs of this concern during the past week other than the sheriff taking temporary possession of their office. The following despatch was printed in the Boston *News Bureau:*

> The Wisconsin stockholders of the Standard Telephone Company, which was to revolutionize the telephone business, have demanded an accounting of the money subscribed by them. Several letters have been written to the officers, and if an accounting is not soon forthcoming suit for the recovery of the money is to be brought.

In regard to this. Mr. C. C. Rogers of Milwaukee, one of the Wisconsin stockholders, said a week earlier :

It is true, we have felt somewhat disappointed at the delays and postponement of active operations, for we had reason to expect that the new telephone would be in use much earlier, but there is no reason to fear that we have been cheated. *Should the undertaking be abandoned, we feel assured that all the money paid in by subscribers will be returned.*

The Milwaukee parties interested in the undertaking are C. C. Rogers, N. S. Murphey, Gustav G. Pabst, E. H. Bottum and H. D. Smith, the Appleton banker. Each one of these, it is said paid in $1,000 cash when the Wisconsin district was organized.

Mr. Rogers has expressed a hope which we believe is very general among the investors in the company's State rights. Will Mr. Barnes or any other responsible party tell the public that it is their intention to return this money if the undertaking is abandoned? We think not.

One of the Chicago dailies reports that "there was consternation in telephone circles all over the country as the result of the exposure of the stock-jobbing methods of the Standard Telephone Company. Locally there was considerable comment on the character of the deal, which embraced so many prominent men as backers and promoters, and which has been pronounced a bare-faced swindle."

It is also said "that a suit will be immediately brought against the parent Standard Company by the New Jersey State Company. The New Jersey corporation is capitalized at $3,000,000 and has a board of twenty directors. Each director paid $1,000 cash for $50,000 stock in the State company, making $1,000,000 in stock that they now nominally hold. The other $2,000,000 in stock went to the original syndicate of four promoters.

"A committee of three directors," it is said, "has been appointed to bring suit against the syndicate, and if necessary to prefer criminal charges against Allen T. Nye, the chief promoter and organizer. It is considered likely that other State companies will follow the lead of the New Jersey corporation, and that the affairs of the Standard Company will soon be involved in a mass of litigation."

The gentlemen whose names have been connected with this enterprise are certainly in an unenviable position. They will soon have to speak or stand convicted of selling their names for the promotion of a very questionable scheme. The entire career of the company has been marked by methods which would have been called criminal if applied by men of no repute. It will be remembered that the original syndicate behind the Standard Telephone Company was made up of Allen T. Nye, Thurlow Weed Barnes, Charles T. Strauss and J. O'Neill. The parent company was capitalized at $10,000,000.

Twenty-one separate district companies were then organized under the laws of Arizona. In exchange for the transfer of patent rights the syndicate took the whole of the capital stock of these twenty-one district companies, ranging from $3,000,000 to $6,000,000 each. They then sold back to themselves and the additional directors in each district company one-third of the capital stock at the rate of $50,000 stock for $1,000 cash. Each person putting in $1,000 cash was promised a directorship. Some prominent men are said to have received $30,000 stock as a bonus for the use of their names. The syndicate pocketed the cash received, and is said to have divided $300,000 in money, besides owning two-thirds of the capital stock in all their district companies.

The principal district companies are:

	Capital.
New York State	$6,000,000
Eastern (New England States)	6,000,000
New Jersey	3,000,000
Pennsylvania	5,000,000
Columbian (District of Columbia, Maryland, Virginia and West Virginia)	4,000,000
Southern (Tennessee, Kentucky, North and South Carolina)	4,000,000
Ohio and Indiana	4,000,000
Michigan	4,000,000
Northwestern (Illinois, Iowa and Wisconsin)	6,000,000
Northern (Minnesota, North and South Dakota)	4,000,000
Central (Missouri, Kansas, Arkansas and Nebraska)	5,000,000
Gulf States (Georgia, Florida, Alabama, Louisiana and Mississippi)	5,000,000
Pacific (Washington, Oregon, Montana, Idaho, Wyoming and Alaska)	5,000,000

This is an imposing showing on paper, and yet, so far as we can learn, after all these months of stock-jobbing not a single Standard telephone exchange is in operation. If there is one we would like to know of it. If there are any patents worth $100 apiece, we would like to know of them. If there was any honest basis whatever for the company's operations, we would like to know of it. If there is any equivalent which they can give honest investors, we would like to know what it consists of; and we defy any one of the promoters to justify the sale of any State or local rights whatever.

The whole structure is already tottering, and if many a heretofore honored man is not discredited and disgraced beyond redemption by its collapse, the best men in the telephone world will be greatly surprised.

ELECTRICITY has not been able to find one of this class who has any confidence whatever in the concern.

It is evident that the insiders are very much disturbed over the turn affairs have recently taken—the exposures of ELECTRICITY, the intended suits for recovery by different State organizations.

In the New York *World* of Sunday, October 27, there was a paid reading notice of over five columns, written in a style which reminds one of Allen T. Nye, booming the company. The whole thing was a conspicuous though ill-timed effort to stem the tide which has set in against the principals.

We quote a few sentences:

In three years from to-day, in place of the 15,000 telephones in use in New York City, and in place of the 4,571 in use in Brooklyn, and of the 4,500 in use in Philadelphia, there will be at least 150,000 in New York City and 100,000 each in Brooklyn and Philadelphia.

The general public has very little conception of the fact that the combined capitalization of the companies comprising what is known as the Bell Telephone system is in the neighborhood of $400,000,000, and that this vast ocean of stock is paying dividends.

The Bell Company in New York City showed total profits in six years of 474 per cent.

The Standard switchboard is a novel departure in exchange work, and marks an epoch in switchboard construction. It is exceedingly cheap to install as well as to maintain. For an exchange of 10,000 subscribers, according to the Standard Company's claim, a switchboard costs, instead of $350,000, only about $20,000. Instead of $80,000 a year for connections, its cost would only be about $60,000; and interest, depreciation and maintenance, instead of being $50,000, would be only $3,000. Each section of the switchboard has, instead of 10,000 jacks, or switching terminals, only about thirty to fifty. The limit of the multiple switchboard now in use all over the United States is at the top notch 10,000 subscribers. The limit of the Standard switchboard is, as above stated, not reached even at 50,000.

No official statement has ever been given out by any authorized agent or officer of the new company, and inquirers at the headquarters of the company, in the Postal Telegraph Building, are politely requested to allow results to speak for themselves.

The Standard Telephone Company's beginning was entirely wrong if its objects were legitimate.

We have no doubt that, despite the refusal of the officers to give out official statements, results will soon speak for themselves.

* * *

Get Together. What ELECTRICITY predicted in the incandescent lamp business is gradually coming true, though not as rapidly as we hoped it would. We refer to the enforced retirement of the makers of inferior and cheap lamps by the working out of natural commercial laws. There have been several suspensions, none of them large enough to create any particular comment. The cutting of prices has gone far enough, however, to convince the public itself that other things than cheapness should be considered in an incandescent lamp. There never were so many poor lamps on the market, nor such a universal protest from users against them. And while the leading manufacturers are turning out better lamps than ever before, they are yet suffering from the evil effects of the competition in "cheapness." The situation, though apparently better than it was a few months ago, is critical. Some of the makers of the best lamps, exasperated at the loss of orders by the underbidding of one cent a lamp on lamps known to be worth less than half as much as their own, are seriously considering cutting the market wide open with a reduction of 50 per cent. in order to drive the trade disturbers out, trusting to an ultimate re-establishment of fair prices. We doubt the wisdom of this plan, though there appears some justification for it.

The most sensible thing would be for the lamp makers to come together in some sort of a combination in which each company would preserve its individuality and work as hard to sell its own product as ever. This could be accomplished by the establishment of a central agency, from which all lamps should be billed at uniform prices for different candle powers and voltages. The selling argument would then be quality alone, and the company refusing to go into the combination would practically confess in advance its lack of confidence in its own product.

There should be in some way a general stiffening of prices, and a constant struggle to turn out the BEST LAMP POSSIBLE. In no other way can the incandescent lighting business hold its own against the competition of small arc lamps (constantly being improved), and against the Welsbach light, which has already made serious inroads on the income of many a central station. And it is the central station men who ought to be more interested than any one else in improving the quality of the lamps. They do not aid in this by buying the cheapest lamp offered. The loss of a few customers by reason of poor, yellowish and offensive looking lamps will more than overbalance the saving of a few cents on initial cost.

The strongest argument the central station man can offer against the Welsbach burner is the superior QUALITY of the incandescent electric light. This quality is only obtainable by the use of the best lamps.

The average production of lamps for this year will be about 50,000 per day. An increase in price of two cents per lamp would thus mean an added profit of $1,000 per day to divide among the various manufacturers.

Lamp makers who are in the business to stay should get together on the basis of better prices and better product.

* * *

Municipal Lighting in Boston. The special committee of the Common Council of the City of Boston appointed to consider the expediency of exercising the authority provided by legislative acts of 1891 concerning the manufacture and distribution of gas and electricity by cities and towns, has made its report.

The committee investigated the lighting systems in the cities of Philadelphia, Marietta, O., Springfield, Ill., Bloomington, Ill., St. Joseph, Mo., Aurora, Ill., Chicago, Michigan City, Ypsilanti and Detroit. As the result of its labors the committee concludes "that Boston was paying too much for electric lighting, and that a great saving could be made and at the same time the citizens could be furnished with an electric light service fully equal to the present, and that it is expedient for the city to establish and maintain a plant for the manufacturing and distributing of electricity for municipal purposes."

Other discoveries made by the committee are stated as follows:

The committee has given sufficient time to the question of the cost of an electric light plant, fortified with the experience of other cities, to be able to state that an overhead line of construction, with 35 to 40 foot cedar poles, shaved and painted, with triple braid No. 6 weather-proof line wire, including everything requisite for such service as the city of Boston would require, can be constructed for less than $300 per mile. In fact your committee are prepared to venture the statement that it can be constructed for $250 per mile.

The plant in Detroit of the finest possible make cost $300 per arc. This includes the cost of expensive real estate, both in land and building. The actual cost of construction will not exceed $168 per arc for an overhead system of 3,000 arcs in Boston, and your committee are positive that they are not in error in making this statement. The additional cost of real estate will of course depend upon the location, but your committee believe that such location can be secured as to bring total cost of plant, including land and buildings, not over $250 per arc. Assuming that an estimate of $250 per arc is correct, the cost to the city of a 3,000-arc plant would be $750,000. The interest on the investment, a fair charge for depreciation and well-paid labor would, in the opinion of your committee, make the total cost not over $75 per arc, and there would be a net saving to the city of at least $125,000 per year.

That electric lighting is to supersede gas is only a question of a short time, and your committee are thoroughly convinced that the best and most economical light for a large city is the electric light It is no longer a question of experiment, and the cost of operating is no longer the exclusive property of the electric light companies. The manufacture by cities of electricity for municipal purposes has demonstrated the fact that the generating of electricity for lighting purposes is an open commercial question, entirely devoid of mechanical difficulties, and proves that the fancy prices charged by the electric light companies, not only in this but in all other cities, are unwarrantable, and it certainly must be a surprise to the City Council and the citizens of Boston that a commercial company receiving such valuable franchises from this city for a merely nominal consideration should take such an advantage of the taxpayers as to charge 100 per cent. more for electric light than it costs to manufacture.

Notwithstanding the suggestive discoveries made by this committee, it is evident to it "that the consummation of a municipal plant, however desirable, is very remote" until certain modifications are made in the act of the Legislature.

* * *

The investigations made by the committee reveal nothing new, nor do they confirm anything, except possibly the inaccuracy and unfairness of the statistics on municipal lighting that have already been compiled. In no case thus far brought to public notice have all the elements entering into the cost of the production of electricity for lighting purposes been taken into account in the estimates made by the advocates of municipal control. Failure or refusal to do so has vitiated all statistics previously prepared. The report of the Boston committee exhibits all the characteristic defects, while it adds nothing but volume to the literature of the subject.

Under the Searchlight.

Views and Opinions on Timely Topics.

MR. AL T. SHOCH has qualified as receiver for the Ottawa (Ill.) Electric Street Railway Company. This is the road, it will be remembered, built by Mr. T. P. Bailey, of Chicago, with General Electric money, to show the citizens of his native town what a great man he had grown to be.

* * *

Still Scheming.

H. M. Byllesby is Trying to Work Another Bond Deal.

A few weeks ago Mr. H. M. Byllesby spent considerable time in Missoula, Mont., endeavoring to carry through a great water-power-electric-light-stock-and-bond scheme, with a bonus from the town of land and subscriptions for $15,000 of the bonds. The effort failed.

Now we understand Mr. Byllesby has returned to to Missoula to try it again.

ELECTRICITY warns the business men of the town that any scheme which Byllesby may propose will be against the best interests of the community.

If there is any water power in the Hell Gate river worth getting, local capital and local people alone should engage in the enterprise. Any company which Byllesby may organize will be on the straight road to bankruptcy as soon as it is incorporated.

The Missoula General Electric Company is one of the characteristic Northwest schemes, and we do not wonder that Byllesby and Coffin desire to get out of it in some way. The population of the town in 1890 was 3,426. The plant was started in that year by Abe Heyman and H. M. Ogden. The first city contract was for ten arc lights. A big debt was piled up with the Northwest General Electric Company. Then Byllesby took hold with a strong hand to apply his regular treatment. He got an option on it, and tried to raise money in St. Paul to buy it, representing that the new company would have *only* $100,000 stock and $100,000 bonds. He told the boys in the St. Paul office that he had made up a syndicate of Messrs. Willins, Weed and Lockey (Northwest General Electric stockholders) to buy it, and every one was invited to come in on the ground floor. "There is large money in it," said Byllesby. But Mr. Lockey sent for Mr. B. F. Meek to ask a few questions, and found that $200,000 of bonds, instead of $100,000, had already been printed before the plant was bought. Mr. Lockey thought that this was a little too much for a town of 3,426 people, and kept his money.

Where the securities are now we do not know, but they appear to have been sold.

At the time Mr. Byllesby took the plant, the following was the extent of the tangible property. Little has been added since :

INVENTORY OF MISSOULA ELECTRIC LIGHT COMPANY'S PROPERTY.

Three lots, as shown on abstract.
One brick station 40 x 65 feet.
One 2-story building on lots used for office supply room and workshop.
Three boilers of 80 horse power each.
Two 35 H. P. Westinghouse engines.
One 65 H. P. Westinghouse engine.
One 80 H. P. compound Westinghouse condensing engine.
Two 50-light arc machines.
One 35-light arc machine.
Two 650-light Thomson-Houston incandescent machines.
One 400-light Edison dynamo.
One 300-light Edison dynamo.
About 36 miles of wire.

We advise Mr. Byllesby to remain in obscurity. The millions of worthless bonds manufactured and sent East by him during his career as president of the Northwest Thomson-Houston and General Electric companies are conclusive proof that there is no further opportunity for him in this business.

And before many months Mr. C. A. Coffin will join him in retirement.

* * *

MR. EDISON, in a recent interview, has announced that he will return to active work in his laboratory as soon as he can secure a competent manager for his mining plant at Ogden. He has offered the place to Prof. W. D. Marks, of Philadelphia, who may accept.

* * *

THE daily paper reports of the sale of the Schuyler Electric Company's factory at Middletown are slightly inaccurate. The General Electric Company paid for the entire property $77,825. This is somewhat less than our estimate of its value in our analysis of General Electric reports.

* * *

THE case of the Adams Electric Railway Company vs. the Lindell Railway Company came up before the United States Circuit Court of Appeals at St. Paul last week. Dr. Adams is confident of a judgment in his favor this time.

* * *

ARGUMENT was heard at Philadelphia last week by Judges Pennypacker and Sulzberger on the question of Councilman Andrew J. De Camp's right to a seat in Common Council as a representative from the Twenty-ninth Ward while holding a stockholder's and manager's interest in the Brush Electric Light Company, which has lighting contracts with the city. Mr. De Camp was elected last spring.

* * *

False Prophecy.

(From the Boston Commercial Bulletin, October 19, 1895.)

> General Electric attracts attention by its comparative strength. Advices from New York, not through news agency channels, have been to pick up this stock on weak spots, as plans were being quietly laid which would make it sell very much higher.

General Electric shares have since sold at 33¾, a drop of 3¾ points in one week.

* * *

The Solid Truth.

People who are contented seldom give the world any of its forward movement.

The Brooklyn Bridge.

The Executive Committee of the Brooklyn Bridge Trustees, which was authorized some time ago to inquire into the advisability of using electric power to do the car switching at the bridge terminals and to heat the cars, and which has visited a number of cities to see how this work was being done elsewhere, has decided to permit the electrical companies to put in experimental plants at the Brooklyn terminal with a view of adopting some one of these systems if it prove to be satisfactory. Chief Engineer Martin was authorized to advertise for proposals.

"High Speed Commercial Telegraphy."

The above was the subject of a lecture delivered by Mr. Patrick B. Delaney before the New York Electrical Society at Columbia College on the 28th inst. Mr. Delaney has devoted his life to the development of multiplex, synchronous and machine telegraphy. The expressed purpose of his lecture was to explain the construction and to illustrate the methods of operation of his most recently perfected devices, by means of which it is possible to transmit upwards of 2,000 words per minute. The apparatus consists of a perforator, upon which the message is prepared by perforating a ribbon of paper ; a transmitter, through which the ribbon is passed, and the receiver, which reproduces by electrolytic action upon a prepared ribbon the impulses imparted at the transmitting end.

It is not claimed by the inventor that his new system will replace the present duplex, quadruplex or multiplex systems for commercial work, but that it has a peculiar field of its own. By an elaborate array of statistics he demonstrated that a line of two wires between New York and Chicago, costing complete $850,000, and transmitting messages at the rate of 400 words per minute, would be able to take care of as many messages as there are now letters transmitted between those points, and at a cost not exceeding 15 cents per message. Thus the telegraph would become the auxiliary of the postal service, and at a tariff within the reach of all.

LEGAL NOTES.

Conduit Railway Litigation.

Charles Bidwell of Toledo, O., has commenced suit in the United States Court at Toledo against the Toledo Consolidated Street Railway Company, now the Toledo Traction Company, to determine the question of infringement of patents Nos. 373,046 and 504,549. These patents are for an electric conduit railway and were granted to Benson Bidwell, father of the complainant.

Elias E. Ries, of Baltimore, and Albert H. Henderson, of Philadelphia, have instituted suit against the Metropolitan Railway Company of Washington, D. C., for infringement of certain patents on conduit railways.

In the suit of the Edison Electric Light Company et al., against James Pass and Albert P. Seymour, of Syracuse, N. Y., a preliminary injunction has been granted restraining the defendants from manufacturing incandescent lamp sockets.

The Siemens & Halske Company of America has instituted suits in the United States Circuit Court at Chicago against the General Incandescent Arc Light Company of New York and E. Baggot of Chicago, for alleged infringement of the Hefner-Alteneck chain-feed arc lamp and the Hoffman cut-out patents.

Lawyer Wainwright, of Manasquan, N. J., has been appointed receiver of the South Jersey Street Railway Company of Point Pleasant, N. J.

The Florida Supreme Court has affirmed the judgment of the lower court, which recognized the right of the City of Jacksonville to furnish lights for commercial purposes.

GENERAL ELECTRIC'S FINANCING POLICY.

Northwest General Electric—The Scheme, the Companies Financed, the Facts and Figures from the Official Record.

HOW BONDS ARE MANUFACTURED FOR NEW ENGLAND INVESTORS.

The Austin Electric Company.

The condition and history of the Austin Electric Company possesses more than usual interest from the fact that after many vicissitudes the plant finally became the personal property of Mr. Charles A. Coffin, who still owns it. Mr. Coffin's fortune is variously estimated now from —$250,000 to +$3,000,000. Whatever it may be, we cannot help but wonder how many securities like those of the Faribault and Austin companies go to make up his pile. The fact, however, that the Austin stock was not unloaded on some outsider does not detract in the least from the justice of our arguments against the swindling methods of Coffin and Byllesby, but rather strengthens it. The stock has been offered to dozens of people in the past three years, and would have been sold if possible. The reasons why it has not been unloaded are the same reasons which account for the slump of General Electric stock from 119 to 25⅞, the winding up of the Northwest Company's campaign, and all the humiliating history of the General Electric enterprise since the summer of 1893, to wit: the loss of public confidence, brought about by the exposures of ELECTRICITY.

The lighting plant in the town of Austin, Minn., was first started in the fall of 1888, by the same gentlemen who put in the plant at Owatonna, and it was put in in much the same way. Pierce Bros. were honest country boys who had read of the fabulous sums to be made in electric lighting. They wanted to try the business, yet had shrewdness enough to keep their money and place the chief burden from the start upon the company whose agents sold them the apparatus and who made such glowing misrepresentations. They had no desire to humbug any one, but they did not propose to be humbugged. And it is on record that when they retired from the electric lighting field the field owed them nothing.

Acting under advice from the Northwest Company's agents, they procured a franchise in the town of Austin, a copy of which we offer in evidence:

[*Certified Copy.*]

ORDINANCE No. 115.

An ordinance granting Pierce Bros. the right to use and occupy the streets, alleys and public grounds in the City of Austin, to erect and maintain poles and wires thereon for electric light and power purposes.

The Common Council of the City of Austin do ordain:

Section 1. That the right, permission and authority is hereby granted to Pierce Brothers (S. H. Pierce & W. S. Pierce), their heirs and assigns, for the term of *twenty-five* years from the date of the passage of this ordinance to erect and maintain in any and all of the streets, alleys and public grounds of the City of Austin, Mower County, Minnesota, poles for electrical purposes, and to place wires and fixtures thereon, also to repair or remove said poles and wires at any time as may be necessary or expedient, provided, however, that the rights hereby granted are subject to the following conditions:

1st. The franchise hereby granted shall not be exclusive.

2d. The right of the City of Austin to use the tops of said poles for *fire alarm purposes* free of charge.

3d. The right to regulate the manner and places in said streets where the same shall be placed, not exceeding *one hundred and twenty-five* (125) *feet apart*, is hereby reserved to the Common Council of the City of Austin, by resolution or ordinance, or by its committees and the right to provide by ordinance or resolution *prohibiting excessive charges* for light to the citizens and inhabitants of said City of Austin.

Amendment to Section one (1) offered by Alderman West, by adding thereto the following:

And provided further, that in the event of said electrical plant not being operated for the space of *sixty days* the City Council may require the poles herein authorized to be removed by said Pierce Bros., or their successors or assigns; and provided further that the franchise hereby granted shall terminate and be null and void upon a failure of said Pierce Brothers, or their successors or assigns, to keep said electrical plant in active operation for the space of three months; and provided further that the City of Austin reserve the right to terminate the franchise hereby granted at any time after ten years by purchasing said electrical and power plant at the actual cost thereof and the actual cost of the poles, wires, lamps and other fixtures.

Section 2. This ordinance shall not be valid as a franchise unless said Pierce Brothers shall, within thirty days from the passage of this ordinance, file with the City Recorder their acceptance of this ordinance and consent to comply with all reasonable ordinances or regulations that may be passed, regulating the maintenance of said poles, and conducting the business of maintaining an electrical plant under this ordinance, and shall have said plant in operation within seven months from the date of the passage of this ordinance.

Section 3. This ordinance shall effect and be in force from and after its passage and approval.

Passed this 8th day of November, 1888.
Approved this 12th day of November, 1888.
Published this 22d day of November, 1888.

Attest: Approved November 12, 1888.
JOHAN WOLD, City Recorder.
O. W. GIBSON, Mayor.

The plant lost money steadily and piled up a large indebtedness with the Northwest Company at St. Paul. At length, in the spring of 1892, Mr. H. M. Byllesby, having taken charge of Mr. Coffin's exploiting and financing work in the Northwest, directed his attention to the Austin plant. It answered all the requirements for the application of the Coffinesque plan. It was losing money, was in an out-of-the-way place, and had never been stocked or bonded. It was ripe for capitalization. Accordingly the Austin Electric Company was incorporated, with $50,000 stock and $50,000 bonds planned to be issued. A copy of the original incorporation papers follows:

[COPY.]

ARTICLES OF INCORPORATION OF THE AUSTIN ELECTRIC COMPANY.

We, the undersigned, for the purpose of organizing and becoming a body corporate under and by virtue of the laws of the State of Minnesota, in such cases made and provided, have adopted and executed the following Articles of Incorporation.

ARTICLE FIRST.

I. The name of this corporation shall be the "Austin Electric Company."

II. The general nature of its business shall be (a) to construct, maintain and operate a plant or plants for manufacturing and generating electricity.

(b) To manufacture, sell and supply electricity for light, heat and power.

III The principal place of business of said corporation shall be in the city of Austin, county of Mower and State of Minnesota.

ARTICLE SECOND.

The time of the commencement of this corporation shall be April 4, 1892, and the period of continuance of said corporation shall be thirty years from said date.

ARTICLE THIRD.

The amount of the capital stock of this corporation shall be fifty thousand ($50,000) dollars, and the same shall be paid in at such times and in such manner as the Board of Directors of this corporation may designate.

ARTICLE FOURTH.

The largest amount of indebtedness or liability to which this corporation shall at any time be subject shall be the sum of fifty thousand ($50,000) dollars.

ARTICLE FIFTH.

The names and places of residence of the persons forming this association for incorporation are as follows: Henry M. Byllesby, St. Paul, Minn.; Howard C. Levis, St. Paul, Minn.; Benjamin F. Meek, Jr., St. Paul, Minn.; Wentworth P. Johnson, St. Paul, Minn.; Winfield S. Pierce, Austin, Minn.

ARTICLE SIXTH.

I. The government of this corporation and the management of its affairs shall be vested in a Board of five Directors, each of whom shall be a stockholder, and in the following officers, viz., a President, Vice-President, Secretary and Treasurer, and such other officers and agents as the Board of Directors may from time to time appoint.

II. The Directors shall be elected at the annual meeting of the corporation on the first Monday in April in each year.

III. The officers of this corporation shall be elected annually by the Board of Directors at their first meeting each year immediately after the annual meeting of the stockholders.

IV. The President, Vice-President, Secretary and Treasurer shall each be Directors, and their terms of office and the term of office of Directors shall be one year and until their successors are duly elected and qualified.

V. The names of the first Board of Directors of this corporation are: Henry M. Byllesby, Howard C. Levis, Benjamin F. Meek, Jr., Wentworth P. Johnson, Winfield S. Pierce, and they shall hold office until the first annual meeting in April, 1893.

ARTICLE SEVENTH.

The capital stock of this corporation shall be divided into five hundred shares of the par value of one hundred ($100) dollars each.

In witness whereof we have hereunto set our hands and seals this 14th day of March, 1892.

H. M. BYLLESBY.
HOWARD C. LEVIS.
BENJAMIN F. MEEK, JR
W. P. JOHNSON.
WINFIELD S. PIERCE.

Signed and sealed in the presence of
J. F. BISHOP.
A. A. BARRY.

State of Minnesota, County of Ramsey, ss.

On this fourteenth day of March, A. D., 1892, before me personally appeared Henry M. Byllesby, Howard C. Levis, Benjamin F. Meek, Jr., Wentworth P. Johnson and Winfield S. Pierce, to me well known to be the same persons who executed the foregoing instrument, and each for himself acknowledged that he executed the same as his free act and deed for the uses and purposes therein expressed.

[Notarial seal] J. F. BISHOP.
Notary Public, Ramsey County, Minnesota.

Office of Register of Deeds, Mower County, State of Minnesota.

I hereby certify that the within instrument was filed for record in this office on the fifteenth day of March, A. D. 1892, at 4 o'clock P. M., and duly recorded in Book "E" of Miscl., page 95.

E. WOOD, Register of Deeds.

Filed for record in this office March 23, 1892, at 9 o'clock A. M. F. P. BROWN, Secretary of State.

It will be noted that, as in the case of all the other local companies organized by Mr. Coffin's exploiters. no local people were interested. We find again the names of Byllesby, Levis, Meek, Johnson, all employés of the Northwest General Electric Company, and W. S. Pierce, who was soon to become an employé of that company.

At this time there was no legitimate reason for any disposition of the plant other than closing it down and getting rid of the apparatus on the best terms possible. It had lost money every month, and the length of pole lines was such as to preclude any profit from the amount of lighting possible to be done in the town. Austin had in 1890 a population of 3,901 people—an ordinary country village. It had no large manufacturing establishments or other enterprises likely to use much light. It had three banks, with an aggregate capital of $150,000.

But the General Electric Company was at the high tide of prosperity, and Mr. Coffin had advised Byllesby that he could take an unlimited number of bonds, provided they did not cost over 60. Of course Mr. Byllesby's only desire was to "boom the business." He had no reason, from his point of view, to trouble himself about the ultimate gain or loss of the people who took the securities. It was no part of his duty to prevent his superior officer from swindling Eastern investors.

The records which we will present are perfect justification of our charge that there was no honest motive behind the capitalization scheme. The size of the town did not warrant it; the plant as it stood was thrown together for a speculation and was unfit for even the small amount of business done The manager wrote to the home office in 1893 as follows:

"This whole steam plant is an abortion from start to finish, and simply places on the company's shoulders the effects of the plans and work of a combination of a pack of fools."

Now let us see the actual results after Mr. Byllesby had taken hold and issued $50,000 of securities, as shown by the record of the first twelve months under his control:

[COPY.]

AUSTIN ELECTRIC COMPANY.

STATEMENT OF EARNINGS AND EXPENSES FOR TWELVE MONTHS ENDING MARCH 31, 1893.

Earnings.

	Inc.	Arc.	
April	$336 88	$154.50	
May	335.24	153.25	
June	333.77	147.50	
July	340.12	176.00	
August	359.76	154.10	
September	375.06	155.00	
October	381.27	156 00	
November	406.11	157.25	
December	418.90	149.50	
January	336.59	174.35	
February	278.52	148.20

Legal expense	70.20	
Boiler compound	8.25	$4,799 9
Surplus for one year		$1,209.

Here we have a surplus of receipts over disbursements of $1,209.28.

The trial balance, taken off at about the same time, showed a plant account of $49,040.50 and *debts* of only $401.30. The plant account in all these statements is the amount at which these companies were carried on the books of the Northwest General Electric Company—the amount which they had cost. The trial balance follows:

[COPY.]

AUSTIN ELECTRIC COMPANY.

TRIAL BALANCE FOR FOUR MONTHS ENDING MARCH 31, 1893.

Plant account	$49,040.50	
Steam plant	242.50	
Electric plant	132 00

Four months after date (without grace) promise to pay

to the order of Northwest General Electric Company

Twenty six hundred, seventy three & 24/100 Dollars

With Exchange

at First National Bank of Austin, Minn.

Value received

AUSTIN ELECTRIC CO.

No. ______ Due ______

AN OBJECT LESSON IN NORTHWEST G. E. EXPLOITING WORK.—(Fac-simile.)

The shortage of the first year's operations may be reckoned thus:

6 per cent. depreciation on $49,040.50	$2,942.43
6 per cent. interest on $50,000 stock	3,000.00
	$5,942.43
Deduct net earnings	1,209.28
Total deficit	$4,733.15

But the longer the plant was run the worse its condition became.

The proportion of earnings to operating expenses, given above, could not be maintained, and was at various dates as follows:

	Earnings.	Exps.	Surplus.
4 mos. ending March 31, 1893	$1,887.40	$1,451.70	$435.70
5 " " April 30, "	2,277.34	2,123 86	153.48
6 " " May 31, "	2,642.14	2,506.93	135.21
7 " " June 30, "	2,993.16	2,775.45	217.71
8 " " July 31, "	3,305.22	3,138.16	167.02
13 " " Dec. 31, "	5,921.84	5,342.17	579.67

At the same time the debts were increasing constantly, and it is evident that the only way a "surplus" could have been counted at all was by deceptive manipulation of accounts. The money owed was chiefly for supplies bought of the Northwest Company, as the Austin Company had no credit elsewhere, and frequently had to borrow coal from the city. The debts grew as follows:

March 31, 1893	$401.30
April 30, "	942.18
May 31, "	729.91
June 30, "	729.91
July 31, "	888.34
Dec. 31, "	3,904.32
March 31, 1894	7,586.16

At the latter date, while the company's insolvency was becoming more and more conspicuous, all the time the Northwest Company had gradually *raised* the amount at which the Austin Company was carried as an asset, as shown by the plant account in the following:

[COPY.]

AUSTIN ELECTRIC COMPANY.

TRIAL BALANCE MARCH 31, 1894.

Plant account	$53,767.11	
General office expense	210.00	
Salary superintendent	650 00	
Wages engineers and firemen	568.06	
General expense	19.89	
Fuel	754.75	
Accounts receivable	473.45	
Water	41.78	
Repairs to electric plants	3.00	
Repairs to steam plant	59.62	
Discount	42.24	
Interest	3.00	
Taxes	145.51	
Insurance	257.50	
Street lines and wire	8 90	
Carbons	50.45	
		$57,055.76

Credits.

Capital stock	$50,000.00	
Notes payable	3,476.87	
Earnings	1,987.74	
General Electric Company	562.95	
Accounts payable	469 62	
Profit and loss	558.58	
		$57,055.76

We will leave to Mr. Coffin and Mr. Byllesby the task of explaining how any company could have a surplus of earnings over expenses from month to month, while its debts were constantly growing, and with no increase in real assets.

As before stated, the Austin plant is one of Mr. Coffin's gems. It is all his. In May of this year he offered it for sale very cheap, and in his letter to a prospective customer enclosed the following statement:

[COPY.]

AUSTIN ELECTRIC COMPANY, AUSTIN, MINN.

COMPARATIVE FINANCIAL AND INCOME STATEMENTS.

Assets.

	May 31, 1894.	Dec. 31, 1894.

November	612.13	876.87	549.67	675.42	62.46	201.45
December	698.71	878.66	573.20	733.80	125.51	144.86
	$5,408.70	$8,457.85	$4,808.19	$7,298.89	$600.51	$1,158.96

1895.	Gross Earnings.	Gross Expenses.	Net.
January	$837.89	$679.73	$153.16
February	780.96	640.80	140.16
March	783.23	602.37	180 86

It will be noted that the plant had apparently improved its condition between March and December of last year. The debt had decreased to $5,213.35 and cash in bank had been raised to the magnificent sum of $32.36.

We will leave for the concluding chapter a consideration of the amount of the actual investment in the Austin plant as shown by the official inventory.

FRANKLIN L. POPE.

Resolutions of the American Institute of Electrical Engineers.

At the regular monthly meeting of the Institute of Electrical Engineers on October 23d the following resolutions were adopted:

Whereas, The American Institute of Electrical Engineers has heard with heartfelt sorrow the sudden death by a lamentable accident of its past President, Franklin Leonard Pope; and

Whereas, We the Members, Council and Officers of the Institute desire to express our profound realization of the bereavement we have sustained, and the sincere grief we experience, and to record in fitting terms our keen appreciation of the great worth and high qualities of our late fellow member, his eminent services to our organization, and his able, unwearying and successful work in applying electrical energy to many useful purposes. It is therefore

Resolved, That by the death of Mr. Pope, called away in the full fruition of manhood and the meridian vigor of intellect, the profession at large has suffered an incalculable loss, and the Institute has been deprived of a most distinguished and valuable member and a wise and sagacious counsellor, endeared to many members by long, pleasant and affectionate intercourse, and esteemed and respected by all, no less for his kindly and warm-hearted nature and dignified simplicity of character, than for his universally acknowledged genius and great ability.

Resolved, That we hereby express the poignant grief wherewith we contemplate the sad event which has taken from us one who, whether in the earliest days of our Association, co-operating in its successful establishment, urbanely and efficiently presiding as our chief executive officer at business and social meetings, discreetly and judiciously performing the unassuming duties of a member of the Committee on Editing, or in the capacity of an individual member conserving the interests of harmony and stability, has uniformly had the dignity of the Institute at heart, and has assiduously, cheerfully and faithfully labored for its welfare.

And while we sincerely mourn the loss of an associate so eminent and useful, thus suddenly withdrawn from the activities of this present life, we most earnestly grieve for the parting from a friend so sincere, faithful and true.

Resolved, That we extend to his stricken family our tenderest sympathy in this the hour of their affliction, and that in testimony thereof a copy of these resolutions be forwarded to them.

Resolved, That these resolutions be appended to the minutes of the Council, and be published in the Transactions of the Institute.

THE BEHAVIOR OF THE CARBON BRUSH ON THE COMMUTATORS OF DIRECT CURRENT POWER GENERATORS.*

BY HARRIS J. RYAN.

The experience of electrical engineers during 1880 to 1890 with dynamo electric machinery of magnitude was almost without exception in connection with generators for supplying incandescent lighting currents. Such generators were generally of the two-pole type with smooth-bodied armature cores, on the surface of which the conductors were mounted and secured in place by means of binding wire. Self-induction of the sections of such armatures was a minimum. The air gaps were large and the M. M. F.'s used for the establishment of the armature induction were in the sizes of generators then in use easily maintained ahead of the maximum M. M. F. of the armature when delivering its full load current. Under these circumstances it was easy to maintain a suitable set of conditions for the successful commutation of the currents by means of metallic brushes, which at that time were universally used. Being used for electric lighting, these generators had a load output that fluctuated slowly, and the attendant from time to time, as the load shifted, would adjust the brushes to that neighborhood of the magnetic fringe under the leading pole tips where the E. M. F. generated by the mechanical motion of the conductors, connected to the commutator segment passing under the brush, would be sufficient to oppose the E. M. F. of self-induction and reverse the current.

When electricity was applied to the propulsion of street cars at Richmond in 1888, for the first time with commercial success, it was found that the method of current commutation that had been an entire success for incandescent lighting was utterly unsuited for the purposes of power supply for such street railway service. At this time Mr. Van Depoele, later connected with the Thomson-Houston Electric Company, thought of the use of carbon in the place of metal for taking the current from the commutators of power generators engaged on this class of work. The idea was tried and found to be a great success, and it is altogether likely that a far greater part than people have thought of the success of the electric street railway has been due to the use of the carbon brush on the street railway generators and motors. In connection with the motors, as well as with the generators, it was found that so long as metallic brushes had to be used the commutators suffered serious disintegration due to the sparking that ensued with the use of metallic brushes, because an attendant could not keep up the changing of the commutation point with every change of the load, for these changes of load both in the motors and generators were found to take place so suddenly, and to vary constantly, that it would be impossible for the attendant, giving his entire time to a set of brushes, to keep them at the non-sparking point of the commutators in those cases where the time of such an attendant could be afforded. It is interesting to note, therefore, just in what manner the carbon brush takes the current off the commutator so that it is unnecessary to have the brushes moved from point to point with every variation of load in order to avoid sparking.

In the Figure, the carbon brush to which we will direct our attention is on the left. On the left side of this brush the current in the armature is traveling from left to right; the opposite of this is the case on the right side, as indicated by the arrow heads below the commutator bars. As the bar, therefore, passes under this brush, as the armature rotates from left to right, the current in the armature coil that is connected to this bar at one end and to its neighbor at the other must be completely reversed. This coil is located in a groove in the armature and is therefore nearly surrounded by laminated iron so that its self-induction is comparatively high. The self-induction E. M. F. formed on the sudden reversal of the current in such a coil is, therefore, correspondingly high. Some sort of E. M. F. then must be available to oppose such self-induction E. M. F. with a balance sufficient to reverse the current against the ohmic resistance. The current delivered by the brush is taken from the commutator bars under it, as indicated by the arrow heads. For the sake of clearness let us number the bars under the brush by calling the left 1, the middle 2, and the right 3. Now remember that carbon has a high specific resistance, and study what happens to the coil when between bars in the position of 1 and 2, and then 2 and 3. Remember also that our purpose in this study is to see how it is that a carbon brush assists in the reversal of the current in the sections under commutation without the aid of E. M. F.'s generated in the fringe of the leading pole tips. To do this it is convenient then to assume that the brushes are in the normal diameter of commutation and that such fringe E. M. F.'s are absent. The armature winding to the left is active in delivering current to the brush through bar No. 1 over the restricted area of contact. This restraint area of contact presents considerable resistance to the passage of the total current from the left which gives rise to much local fall of potential. That diverts a considerable portion of the current through the coil between bars 1 and 2 to the brush through bar No. 2. The entire surface of this bar is under the brush, to which it connects with less contact resistance therefore than at No. 1. Thus far there is observed no tendency to reverse the current in the coil between the bars 1 and 2. A moment later this coil will occupy the same position as that between 2 and 3. What occurs in the position 2–3? The armature current from the right is being delivered to the brush as indicated by the arrow heads at *a*. Here again is a restricted area of contact constantly diminishing with increasing resistance, so that just before No. 3 moves from under the brush a high local fall of potential occurs that causes some of the total armature pressure to divert the current by way of the coil 2–3 against the current already in that coil, causing it to reverse quickly in opposition to the E. M. F. self-induction. It is in this way that the high specific resistance of the carbon brush is used advantageously for effecting the commutation of current without the aid of pole fringe E. M. F.'s. This property of the brush cannot be depended upon for the complete commutation of the full current without sparking, though in most generators with armatures of the iron-clad type where self-induction of the coils is highest, fully half of the current may thus be commutated. In street railway generator practice, therefore, it is usual to adjust the brush at no load into that neighborhood of the magnetic fringe of the leading pole tip where the E. M. F.'s mechanically generated are sufficient to reverse one-half of the normal current. These E. M. F.'s are not large enough to cause serious short circuiting of the coils under commutation at no load and assist the carbon brush to reverse the current at the full normal load. It is in this way that generators are now made to operate without disruptive effects of the commutator under the most trying conditions of load variation.

LOCAL ANNEALING OF HARD-FACED ARMOR PLATES.*

BY HERMANN LEMP, JR.

Every one is now more or less familiar with the Thomson electric welding process, which in the past year has been introduced in almost every metal industry in one shape or another. This process created a new field in the technical application of currents of large volume and small E. M. F., a field which, while it was primarily intended for welding, naturally suggested a number of other applications to so fertile an inventor as Prof. Thomson; and so it happened that early in its fundamental inception the use of large currents was contemplated to be utilized for heating plain metal bars or parts of sheet billets, etc., for forging purposes, to rivet, upset, to temper or withdraw the temper, or to be worked upon in any well-known manner while being kept heated by the current.

It has been the good fortune of the writer to lately work out one of these novel applications, and since the literature concerning this branch of electrotechnics is somewhat limited, he has thought it advisable to bring an account of the same before the Institute.

One of the latest advances in the making of protective armor for battle-ships, or even forts, has been the introduction of what is known as the Harvey process. For those not conversant with the latter, I will briefly state that it consists in taking an ordinary low carbon steel plate and introducing an additional percentage of carbon into the surface metal, thus changing the crust to the depth of about an inch into a steel resembling tool steel. A plate thus treated is lastly water-hardened, similarly to an ordinary tool, and by experience has shown to offer, under equal conditions, more resistance to the impact of a projectile than any other armor known. And therefore we will take this as an illustration of hard-faced armor. The extreme hardness of the surface of a Harvey plate, while exceedingly valuable in preventing projectiles from piercing it, has a disadvantage when it is required to be pierced by a drill and tap. Such holes may be required either for fastening ladders, swivels or other appliances to the hull of the vessel, or to fasten T flanges supporting the deck to barbettes or turrets.

The methods heretofore used to produce these holes were principally two:

1. To protect the surface of the plate in patches or strips, to prevent carburation, wherever holes were expected to be drilled.

2. To make accurate drawings and patterns of each plate beforehand, to which all holes are drilled before plate is hardened.

Plan No. 1 was practised in the United States until it had to be abandoned. In practice it was found that numerous alterations in construction, errors in either draughting-room or mills, made it necessary to pierce holes where no provisions for annealing were made. It also happened quite frequently that the method for prevention of carburation did not always work satisfactorily, and while white paint indicated well enough where soft metal was expected, very often hard metal was actually found. Hence it was patent from the first that some process was needed to rectify errors of this kind. Experiments were made with the oxy-hydrogen blowpipe, or the electric arc, to anneal such spots as were required to be drilled, and numerous mechanical devices for drilling, with drills of every design and method of tempering, were tried, until it seemed that the case was without a remedy.

It was at this stage that the problem was referred to the Thomson Electric Welding Company of Lynn, and experiments were immediately undertaken to solve it. The process and apparatus necessary to carry it out, all resulting from the experiments undertaken, will be described presently.

---

* *The Sibley Journal of Engineering.*

* A paper presented at the 100th Meeting of the American Institute of Electrical Engineers, New York and Chicago, October 23, 1895.

The second method, which is used in England, has the advantage over the first that there is no difficulty in carrying it out provided there are no alterations made and no errors committed. The present method of construction seems to be to make, beforehand, a complete *model* of the vessel to be built; then make accurate drawings and full-size patterns of every plate, giving the exact location of every hole. These are then bored, tapped and countersunk to a depth of approximately ⅜'' and of a much larger diameter, filled with clay, and then the plate as a whole is heated and hardened with water. (See Fig. 1.)

This method works apparently all right, although in spite of drawings and models errors are made. There is no doubt, however, that it is a slow and very costly method of working, and would hardly ever be resorted to in the United States.

From the above it seems clear that there has existed a need for a process by means of which isolated spots, regardless of location, might be annealed so as to permit drilling and tapping.

If by sending a current of large volume through any spot thus to be treated the spot is brought to a temperature of approximately 1000° F., there can be no doubt that the temper has been withdrawn. Experiments carried out to that effect at once showed, however, that upon taking off the heating current the heat was so rapidly conducted away by the surrounding metal masses as to cause the heated spot to become chilled just as effectually as if it had been plunged into cold water. No method of outside protection of the heated spot would prevent this, and the *gradual* cooling of the spot had to be attained by different means, namely, a gradual and slow withdrawing of the heating current. The method of introducing the annealing current is best shown in Fig. 2.

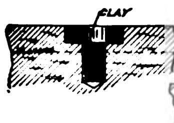

FIG. 1.

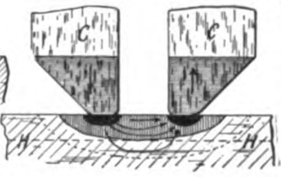

FIG. 2.

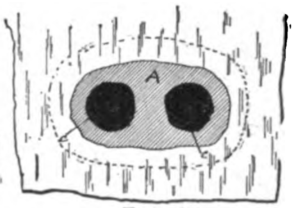

FIG. 3.

C C are two copper contacts cooled by water circulating inside. The current enters the plate by one end and leaves it by the other. Right under the contact, the metal comes to a bright cherry heat (shown in black), while the portion intervening and partly surrounding the contacts acquires a temperature of just a visible red. Line H H indicates where the influence of the Harvey treatment stops.

The shaded portion in Figs. 2 and 3 shows the zone softened and ready to be machined, while the dotted line shows how far the heat radiation would cause the metal to turn blue. When cooled, the annealed portion shows a chocolate color, while the place where the contacts have been resting is scaled and hard, and cannot be touched by a tool to a depth of about ¼''. These places can again be annealed later on, if required.

The apparatus necessary to carry out this process consists of the generator, the annealer proper (transformer) and the regulating apparatus.

The generator is commonly a separately excited alternator of variable potential, of a maximum of 300 volts and 100 amperes. The frequency, preferably, should be low, 50 cycles per second being used. When more than one annealer is to be run simultaneously from one generator, constant E. M. F. of the latter should be used, and each annealer regulated separately by a reactive coil. The annealer proper is a transformer similar to the well-known welding transformers. As the apparatus is to be operated outdoors, on board of vessels during construction, it is important that the same may be handled with immunity from electric shocks, even when operated in mist and rain.

To meet these conditions a copper-clad type of transformer is used, one in which the secondary is composed of two copper castings each having a rectangular groove, which two halves, when bolted together, form a closed rectangular frame in which the primary is held enclosed. The hollow space intervening between primary and secondary is moreover filled with a heavy oil, which acts both as the insulator and conductor of heat from primary to secondary. The secondary, by completely surrounding the primary, affords an excellent mechanical protection, and prevents electric as well as magnetic leakage. The primary is a copper ribbon insulated with asbestos, and the ratio of conversion is 100 to 1. The transformer has two trunnions fastened to its sides, in a line a little above the center of gravity, which trunnions swing in bearings, part of a yoke which straddles the whole. The yoke in its turn has a hook which may be secured to the latter at any place of the arch, thus allowing the transformer to be suspended, like a compass in gimbals, in any position desired.

It goes without saying that the copper castings which compose the secondary are cut through at one place in the circuit. On either side of the cut, two short platforms form the base for copper contacts of various shapes and sizes, by means of which the currents are made to enter and leave the plate to be annealed. These copper contacts are of forged copper, hollowed out to receive water circulation for cooling purposes, and terminate in narrow tips rounded at the end.

The weight of the whole annealer, being approximately 1,000 pounds, is sufficient to give proper contact pressure for all work on a horizontal plate. When inclined surfaces, vertical or otherwise, are to be worked upon, the transformer is suspended so that its weight shall not interfere with the contact pressure, which is obtained for work by bracing the contacts directly with wooden wedges against any object near by. On the outside of a hull, it is proposed to use a pair of electro-magnets, which are made to hold themselves against the iron hull, and form a support for the annealer.

The remarkable thing is the great amount of current that is being carried by the copper contacts into the plate. The contact surface is seldom more than about ½'' square, and yet 10,000 amperes are made to flow through it continually. This is equivalent to 40,000 amperes per square inch, a density which is only possible on account of the thorough cooling by the water circulation.

The regulating apparatus is in most cases simply a rheostat in series with the field of the generator. When more annealers than one are run simultaneously from one generator, as mentioned before, a reactive coil is interposed between the two, and this latter has been made automatic; that is to say, provided with a dash-pot, which permits the current to be reduced uniformly and at any given rate it is set for.

This reactive coil, Fig. 4, is composed of a solenoid coil of cable, well insulated, having a movable laminated iron core which is raised out of the coil by means of a leather strap and winch. The core is composed of thin iron strips placed side by side around a circle and projecting radially from the same, and being held on top and bottom by a slate disk, in a manner similar to the securing of the copper segments of a commutator. No insulation of the core is necessary, and good ventilation is obtained. The core once raised out of the coil tends to return by gravity and the attraction of the solenoid, but is checked in its descent by a pair of dash-pots, one on each side of coil. These latter communicate with each other, top and bottom, and have one of the pistons provided with a valve which opens when the core is raised, and closes when the core descends. The dash-pot cylinders are filled with a light mineral oil, which does not freeze nor clog under any ordinary conditions of temperature. An adjustable by-pass valve allows the oil to flow from the tube to the top side opposite. By opening or closing this valve more or less, any rate of descent, and consequently diminution of current, can be uniformly obtained, without requiring any skill on the part of the operator.

The annealing operation is carried out as follows: The transformer is placed in position the contacts touching the plate either side of the place marked to be annealed, and the primary current brought up by means of a rheostat to from 75 amperes to 90 amperes for about two minutes, according to the size of spot to be annealed, which will bring the metal to a dull red heat, a temperature at which a pine stick catches fire when held in contact with the plate. If no reactive coil is used, the current is now diminished by turning the rheostat one point every minute. If the reactive coil is used, the core is now raised by winch, the coil put in circuit by opening a short-circuiting switch, and then is allowed to descend on its own account. The operation generally takes *seven minutes*, all told. No difficulty has been experienced from the beginning. The annealing of individual spots was, however, only the stepping-stone to a more important work of a similar nature, work which was about to be given up, owing to what was considered insurmountable difficulties.

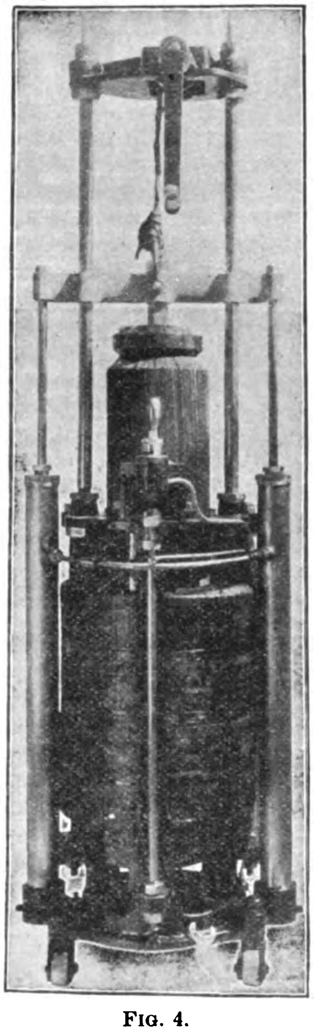

FIG. 4.

In the construction of a modern man-of-war, there are many armor plates which act as shields to the guns, and have to be perforated to allow the gun muzzle to pass through and to be either raised or lowered. Some of these shields are circular or oval with narrow edges around the ports. In the case of

Harveyed plate, to perforate these shields after carburation and before being water-hardened was the only possible way, since previous experiments had shown that prevention of carburation could not be relied on, and no process was known to anneal the plate locally after hardening. The hardening of a plate once perforated showed itself to be, however, almost impossible; in fact, a matter of chance. In most cases the plate cracked in two, as shown in Fig. 9, or the whole plate became distorted in such a way that it could not be used. As individual spots for holes could be annealed, there could be no doubt that a series of annealed spots could be likewise obtained by the electric process, following a line along which a cutting tool was expected to be run. The first attempt, therefore, and made in England, was to anneal a number of spots in proximity to each other in such a way that the annealed zones should overlap each other.

As described above, it is very important that the temperature of any individual part should be gradually and slowly withdrawn; and while for individual spots the only possible way was to do this by gradually diminishing the current, it was obvious that when a line was to be annealed, instead of annealing a number of spots side by side, the same effect of withdrawing the heat gradually from one portion could be obtained by moving the apparatus itself relatively to the plate to be treated. The rate of this movement, of course, depended upon the rate at which the temperature should be allowed to fall in any particular spot to prevent chilling. The apparatus was therefore arranged to be moved along a line to be annealed, the motion being obtained by an ordinary screw and nut held in a bracket, the nut being turned at a predetermined rate controlled by a watch. It was found that a speed of about ¼″ per minute was sufficiently slow to ensure thorough annealing.

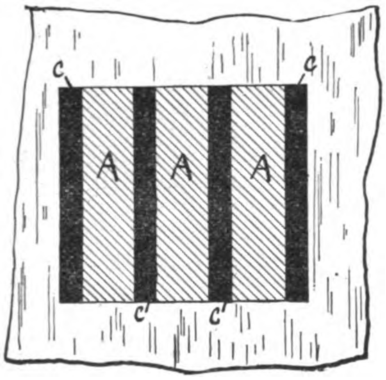

FIG. 5.

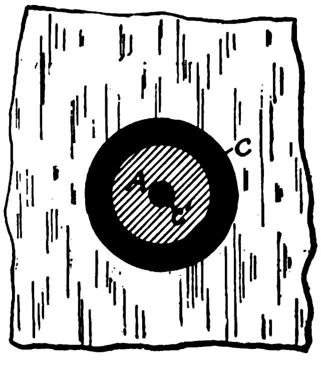

FIG. 6.

The copper contacts were of the simplest kind, as described above, bedding themselves partially in the surface, and when being dragged along by the screw and nut raised in front of themselves a burr or chip similar to a planing tool. After a whole day's continuous use the copper contacts were found intact, while a number of chips from the steel surface were lying about. We thus had the peculiar phenomenon of a hard steel chip cut with a copper tool.

Upon the completion of the work, it was found that a strip about 2¼″ wide throughout the length over which the machine had been moved could be operated upon by drills or a shaper, in a manner as easily as if it had never been hardened before.

In the work just described, the apparatus was moved about, but in regular practice it would be better to construct a machine consisting of a large bed, on which the plate to be treated may be fastened and moved in any direction automatically at a predetermined speed, while the annealer proper is suspended in a given position above plate, as shown in Fig. 10. The annealing operation occupies but a small percentage of the time required for the cutting.

It is unnecessary to state that when the apparatus is used for continuous annealing, the primary current is kept at a nearly constant value, the diminishing of heat at any individual spot being obtained solely by the moving of the apparatus from it. As mentioned before, the places where the contacts are passing over the plate, being brought to a higher temperature than any other, remain hard. Experience has demonstrated, however, that they may be re-annealed later on by treating the spots in the same way as any other hard spot on the plate. By this means we are therefore able to anneal any shaped portions, not merely lines. This is best seen in Fig. 5, in which a series of strips are annealed side by side (shown in shaded lines A). The hard-faced surface is then removed on such places by a planer and drill; the machine is then run a second time over the annealed strips, resting it this time on the bottom of the groove and on the softer metal, thus annealing the ridges C left between the annealed strips, on which ridges the contacts were running previously. When all these strips are annealed they may be removed by machine tools without any further difficulty. In a similar manner a large round place may be annealed, as shown by Fig. 6. The transformer is set on the plate, one contact resting on C′, the other at any other place in circle C; the apparatus is then slowly revolved around contact C′ as a center, until the second contact has completed the circle C. The shaded portion A represents now the annealed surface, which is removed by a cutting tool. The contacts are then made to rest on either side of the center C′, and the latter is annealed and removed in its turn.

The apparatus may also be used for the reversal of the annealing process; that is to say, for creating isolated hard spots in soft tool steel by sending a current through the spot to be hardened until it reaches a bright cherry heat, and then suddenly removing the current or machine.

Various other applications will suggest themselves in the operation of this process, already adopted by the United States Government. It may be used in the construction of burglar-proof safes, for dies and punches, for projectiles, and other articles of a similar nature.

Y. M. C. A. Business Institute.—Popular Lectures.

The Twenty-third Street Branch of the Young Men's Christian Association of this city is very fortunate in securing as Instructor of Electrical Engineering in their Educational Department Frederick M. Pedersen, E.E., Assistant Engineer of the Crocker-Wheeler Electric Company. A course of fifty lectures will be given on Wednesday and Saturday evenings throughout the winter. The lectures will be grouped under four general divisions as follows:

1. Introduction. Fundamental Units.
2. Sources of Electricity.
3. Electrical Measurements.
4. Chief Commercial Applications of Electricity.

All young men interested in such a course may obtain full information by applying in person or by letter to the Educational Director, No. 52 East 23d street, New York City.

Three electric freight engines are in the course of construction at the Baldwin Locomotive Works, under the direction of engineers of the Westinghouse Electric and Manufacturing Company. Two will be used for switching purposes, and the other is to be placed on exhibition.

The Microphone Question.

We are in receipt of the following two communications from "Hello," which although almost too long for publication we give in full, requesting, however, that our correspondent, from whom we are always glad to hear, will endeavor to be more brief.

To the Editor of ELECTRICITY.

Sir: Begging pardon for my seeming positiveness in my last communication, October 9, and showing such lamentable ignorance (any ignorance short of infinite wisdom is lamentable) of the subject of acoustics, I will try to be more moderate.

I enter this discussion realizing full well the superior advantage an editor has in an argument of this nature. However, I feel that the editor of ELECTRICITY will not take advantage of his position to extinguish his opponent. Further, I desire more light upon this subject, and I presume there are others in the same boat. If I am wrong no one will be more willing to accept the truth as it may be shown. Though I have studied these subjects for years, yet the more I study the less I think I know.

You ask: "On what does 'Hello' base his statements that improvements in the microphone have been in the line of Reis not the Berliner (method)?" All the difference I can see between the Reis and Berliner inventions is in the "opposing" electrodes (I use Berliner's expression), that is, the electrode held against the vibrating plate (1). In the Berliner the opposing electrode is "rigidly-held" while that of Reis is flexible. Not one of the many microphones of the present day has a rigidly held opposing electrode, so far as I have been able to discover. Even the Hunnings type has in reality flexible opposing electrodes.

To prove that I am not in the wrong in stating that tones cannot be produced by making and breaking the circuit would take up too much of your space for me to have the face to ask. I reiterate here that tones cannot be produced by a make and break circuit, that is, by a Reis microphone. In my former communication I did not so qualify my statement, supposing since we were discussing microphones that it would be taken for granted that I meant that tones cannot be produced by a Reis microphone by making and breaking the circuit. (2). Let me state right here that Reis's theory of how tones were produced by his microphone is not correct.

I am not way off when I say that experience has proven that in no other way can sound waves be transmitted by the agency of a battery 'phone other than that of varying the pressure between the electrodes. I was discussing what the Supreme Court said about battery 'phones transmitting sound waves by impinging sound waves against a diaphragm. Any fool knows that a vibrator or buzzer is made by a make and break contact. Reis's telephone was not either of these (3).

"Bell specified several methods, one of which was by varying the depth of immersion of one of the electrodes in the liquid." Is not this one method by which the electrodes are in constant contact? Bell did not mention constant contact in his claim. In this you are right, but the constant contact is there all the same and goes with the patent which is now public property. Bell had a constant contact method prior to Berliner, and to Bell, if either, belonged the broad claim of constant contact. Gradually increasing and diminishing the resistance is one and the same thing as constant contact, because if the contact be not constant the contact is a make and break and consequently the increase and decrease is instantaneous, not gradual, as required by Bell's 4th claim. Bell's sinusoidal curves cannot be made by a make and break contact, for during the interval of open contact the line ceases to be a curve and becomes a right line. "Berliner claims to have discovered that this method (constant contact) was effective and patented it." He may have discovered the theory, but he certainly was not the first to produce the art. The discovery of a theory is not patentable, but a discovery of an art is. Art is not theory, nor is theory art.

I might rest my argument right here, but let us look at this from another standpoint. If to Berliner belongs the broad claim of a constant contact, and had Bell attempted to use his liquid electrode method as he described and claimed in his '76 patent, Berliner could have stopped him from using it upon the plea that Bell's electrodes were in constant contact. Right here a decision of the Supreme Court is apropos. "A broad claim so expansive as to exclude all previous or future inventions for the same purpose is invalid," 1 Wall, 531.

To show that Bell's knowledge and foresight were such as to forestall any such claim as made by Berliner, I copy from his '76 patent, page 1, beginning at line 26: "The advantages I claim to derive from the use of an undulatory current in the place of a merely intermittent one are . . . second, that a closed circuit and single main battery may be used . . . . fifth, and that as the circuit is never broken a spark-arrester becomes unnecessary." (A spark arrester becomes necessary when an intermittent current is used.) Bell expressly states that a make and break circuit produces an intermittent current. Bell's whole invention is based on an undulatory current whose continuity is never broken be it an induced current or a battery current—whether it be a magneto 'phone or a battery 'phone. The circuit being never broken, the electrodes are always in constant contact. HELLO.

Chicago, October 17.

To the Editor of ELECTRICITY.

Sir: I notice in your remarks in reply to a correspondent of yours, October 16th issue, under the caption of "The Telephone Situation," in which you assume that the intention of the inventor limits the scope of his invention; that the theory of the inventor limits his invention to his idea. Neither the law nor the courts will bear you out. The United States Court in speaking of a certain claim says: "The claim is not as broad as the invention." Applying the same to Reis's, his idea, his intention, his theory was not as broad as his invention. (4) Reis's invention belongs to the public no matter what his theory or idea was. It is laid down by the courts that "there can be no patent for a mere principle. The discoverer of a natural force or scientific fact cannot have a patent for that." According to your article, Berliner discovered a scientific fact, a theory, a principle, and is entitled to a patent thereon. The above quoted decision does not sustain you in this assertion. You say, "his (Reis's) instrument probably did, at times, transmit electrical undulations similar to those necessary for articulate speech." This is all the admission I want. The public owns his invention in all its entirety, no matter what was in his mind. His was not a lost art. All that he would have been entitled to had he taken out letters patent for his invention belongs to the public. It makes no difference what his views were, or what his intentions were, or a lack of knowledge of the scientific fact connected therewith. They would not affect his claim had he patented the art of transmission of articulate speech. This point has been decided times without number. Let us give your idea a practical application. (5) The public are prohibited from using a microphone constructed after the pattern of a Reis instrument because of Berliner's patent. How absurd. You see where your arguments will lead you. Your premises are entirely wrong.

(6) But no matter what your, Mr. Berliner's or my ideas may be, the question is how will the Supreme Court view it? All the members who decided in favor of Bell as against Reis, Drawbaugh and others are now dead—the Chief Justice who delivered the opinion died within four days after reading the opinion of the court. The Justices who sat in those cases now living are Justices Field and Harlan. Mr. Justice Bradley, now dead, in reading the dissenting opinion said: "Mr. Justice Field, Mr. Justice Harlan and myself are not able to concur with the other members of the court sitting in those cases, in the result which has been reached by them, without expressing an opinion on other issues; the point on which we dissent relates to the defence made on the alleged invention of Daniel Drawbaugh, and applies to all cases in which that invention is set up. We think that Drawbaugh anticipated the invention of Mr. Bell, who, at most, is not claimed to have invented the speaking telephone prior to June 16, 1875." If these Justices thought at that time that Drawbaugh anticipated Bell, they most assuredly think that Reis anticipates Berliner. What new light has since been thrown upon the subject to change their opinion? None at all. We have reason to believe that Mr. Justice Brewer concurs with them in that opinion, and at least one other Justice, basing our belief on the tenor of some of their decisions in telephone cases. This leaves the bench nearly evenly divided. Taking even chances on the remaining Justices, there will be at least six against Berliner to at most three for him.

I am now discussing the broadness of Berliner's claims, not the legality of his patent. I do not think his patent will be annulled. It is a good patent so far as it goes, but like all other specific patents, limited to "as shown and described."

On the other subject referred to, of the Watson patent, permit me to call your attention to the British patent No. 1958, dated May 12, 1880, sealed Nov. 12, 1880, expired May 12, 1894, taken out by George Lee Andrus, of Boston, and Thomas Augustus Watson, of Everett, Mass., containing 32 claims in number, all of which are now public property in the United States. From its specifications I extract: "Its essential features are a switching device which normally connects 'line in' with 'line out' by the weight of the telephone when the latter is on its support, and when the telephone is removed from its support automatically connects 'line in' to earth through the telephone, and is capable of being moved to a position so that 'line in' will be connected to earth through the telephone when the latter is removed from its support; a device which holds the switching device in its position when the telephone is not on its support, but releases the switching device by the action of the weight of the telephone when the latter is placed on its support, and a device which acts to return the switching device to its normal position when released."

The gravity switch of Rooseveldt will not expire until next May, yet all the other elements contained in claim 1 of the Watson patent No. 270,522 are included in the above-mentioned British patent. It will be seen that the British patent was issued before Watson's American patent. HELLO.

Chicago, October 19.

Replying to the above according to bracketed numbers:

(1) The generic difference between the Reis and Berliner methods is that in the former it was intended that the contact should *not* be maintained, and in the latter that it *should* be maintained.

As a matter of principle it does not matter whether the variation in pressure between the electrodes is permitted by the elasticity of the substance of the electrodes entirely or by that and an elastic mounting combined.

The soul of the Blake invention, for instance, consisted in the inertia of the weighted anvil. The soul of the Reis transmitter consisted in the almost entire absence of the inertia in one of the electrodes which enabled it to break contact upon the slightest vibration of the diaphragm.

Practically it does matter, because an elastic mounting of the electrode enables it to follow up the vibrations of the diaphragm through a wider range of vibrations without breaking contact, but the aim of the elastic mounting is to *prevent* breaking contact.

(2) There would doubtless be no difference of opinion between our correspondent and ourselves if we gave the same definition to the word "*tone.*" Musical sounds differ from each other in respect to *intensity*, *pitch* or *tone* and *character* or timbre.

Intensity, pitch or tone can be produced by a make and break circuit, as was employed by Reis. Character or timbre, which depends upon the *form* of the sound waves—upon the *number* and *intensity* of the various *tones* which make up the compound note—cannot be thus reproduced.

(3) Our correspondent's position on this question seems to us too absurd to admit of argument.

(4) Hello's contention that an idea is not patentable is, of course, correct. The mere accomplishing of results is also not patentable, but a new way of accomplishing results is patentable. It does not matter, as he says, whether the inventor's theory of how he accomplishes his results is right or wrong, but it does matter whether his method is the same as or different from existing methods. Supposing that it were true that articulate speech could be transmitted by means of interrupted currents as well as by undulatory currents, A patents a device which transmits speech by interrupted currents and B patents a device which depends for its action upon undulatory currents. Both, we will say, are equally effective. The two patents are thrown into interference. Will any one deny that it would be a good defence for either party to show that the results, although identical, were accomplished in radically different ways?

(5) The public is not prohibited from using a microphone constructed after the pattern of a Reis instrument because of Berliner's patent. There can be no conflict between the two methods unless it is admitted that Reis and Berliner discovered the same method of producing the same results. The evidence seems conclusive to us that Reis's invention and Berliner's or Bell's disclosed entirely different methods, and that Reis's instrument was carefully constructed with the *intention* that it should only act in a given way—that that *way* of action was what constituted his invention, and if he had patented it he would be protected only in so far as it did act in the way intended.

(6) We cannot forestall the opinion of the Supreme Court. Our opinion is, of course, of comparatively little importance, because whatever the opinion of the Supreme Court may be it will be the *law*. But in weighing the evidence as it appears before us we think it exceedingly improbable that the Supreme Court will hold that Reis anticipated Bell and therefore Berliner.

The Philadelphia Consolidation.

Arrangements have been made for a ninety-nine-year lease of the Philadelphia Edison Electric Light Company to the Pennsylvania Light, Heat and Power Company. The latter corporation will guarantee a dividend upon the $2,000,000 stock of the Edison Company at the rate of 8 per cent. per annum, which is the dividend now paid. After two years 9 per cent. dividends are guaranteed. Edison stock has already been issued to the amount of $1,847,222. It is also expected that all the other lighting companies in the city will be absorbed by this new corporation, which is capitalized at $10,000,000. The companies with their present capitalizations are as follows:

Company.	Capital.
Edison	$1,847,222
Brush	1,000,000
Suburban	300,000
Manufacturers	203,560
Powelton	450,000
Diamond	250,000
Columbia	66,000
Total	$4,116,782

The active promoter of the scheme has been Mr. W. W. Gibbs, of the Electric Storage Battery Company, and his associates include Mr. Martin Moloney of the Siemens & Halske Company, W. L. Elkins, Edwin S. Cramp, District Attorney Geo. S. Graham, Samuel R. Shipley, George R. Philler, Hamilton Disston, Rudolph Blankenburg, William H. Rhawn, Edward J. Matthews, Sydney F. Tyler, Charles T. Yerkes, J. J. Sullivan, E. D. Toland, Edward C. Lee and Clement A. Griscom.

The advantages urged for the combine are concentration of authority and the lopping off of unnecessary expenses.

GENERAL NEWS.

What is Going on in the Electrical World.

Creede, Col.—The electric light plant was destroyed in the late disastrous fire.

Phœnix, Ariz.—The Gardiner electric light works have been purchased by the Phœnix Light and Fuel Company.

Harlin, Tex.—The council has accepted the proposition of R. M. Odell & Co. to put in a waterworks and electric system.

Northampton, Mass.—A strong move is being made looking to the building of an electric road from Northampton to Hatfield.

Buffalo, N. Y.—The Aldermen have put off the further consideration of the Niagara Power franchise until November 13.

East Haddam, Conn.—A movement is on foot to establish an electric car line between East Haddam and Moodus, a distance of four miles.

Indianapolis, Ind.—The Citizens' Street Railroad Company is about to add to its plant an establishment for the manufacture of cars.

Saratoga, N. Y.—The board of street commissioners have decided to abolish naphtha lamps and use electricity altogether in lighting the streets.

Hollister, Cal.—The Hollister Water Company are about to put in an electric generating plant on Poscadero Creek, about twelve miles from Hollister.

Little Falls, N. Y.—President Tylee of the Little Falls and Richfield Springs Electric Railroad has accepted the franchise granted by the city council.

Albany, N. Y.—The Railroad Commissioners have approved of the use of electricity as a motive power on the New York, Elmsford & White Plains Street Railroad.

Lansingburg, N. Y.—The Western Electric Company of Chicago have purchased property here for $10,500 on which to establish the plant for the new electric light system.

Jeffersonville, Ind.—It is stated that a Southern syndicate has purchased the property of the Ohio Falls Street Car Company and will convert the railway into an electric line.

Dundee, Mich.—There is every prospect now that the electric street car line connecting Dundee and Monroe will be built. The line will probably cross the Raisin river at Raisinville.

Palmyra, N. Y.—There is talk here of building an electric road for freight and passengers between Palmyra and Marion. The electric light company is in favor of establishing such a line.

Durand, Mich.—The question of bonding this town for $10,000 to put in an electric light plant has been submitted to a vote of the citizens with the usual result—a majority vote in the affirmative.

Jamestown, N. Y.—This city has decided to go into the lighting business on a larger scale than heretofore, and to that end new machines and additional apparatus will be ordered for the municipal plant.

Kansas City, Kan.—Officers were elected recently by the Kansas City and Leavenworth Electric Railway Company as follows: President, Horace Keefer; vice-president, Edward Carroll; secretary, J. C. Stone, Jr.

Lynn, Mass.—The threatened strike at the General Electric works here has been carried out, the moulders having quit work in a body. It is reported that a strike of the moulders at the Schenectady works also is imminent.

Westfield, Mass.—Pomeroy & VanDeusen have had a new electric light plant added to the equipment of their whip factory, which is now lighted by electricity. The proprietors find this a great improvement over the old system of lighting.

Dexter, Mo.—At the election held here a few days ago it was voted to give a ten-year electric light franchise to Grant Gillespie, of Dexter, and E. L. Hawks, of Puxico. They are to furnish the city with forty 32 c. p. incandescent lights.

Chicago.—Preliminary steps have been taken towards extensive improvements in the West Side parks and their connecting boulevards. A $50,000 electric light plant for the lighting of the parks is among the improvements suggested.

Shamokin, Pa.—Work has been commenced on the new trolley line between Sunbury and Seling's Grove, a distance of ten miles. Major J. H. Hamilton, of Shamokin, is the projector of the enterprise, which is backed by Philadelphia capitalists.

Independence, Ia.—The city plant has just been completed here at a total cost of $25,286. All construction has been of the best. The capacity is 3,500 lights, and the large alternator is of the latest type made by the Standard Electric Company of Chicago.

Hartford, Ky.—Col. A. J. Casey, of Owensboro, who is interested in the proposed electric railway between Hartford and Beaver Dam, via Hamilton, says the company is only waiting for the report of the surveyors before proceeding further in the undertaking.

Vicksburg, Miss.—Chester A. McFarland, superintendent of the Vicksburg Transit and Electric Light Company, states that the actual construction of the railway, power house and plant will be commenced within thirty days and pushed to an early completion.

Boston, Mass.—After the 1st of November the law compelling electric railroad companies in this State to heat their cars by electricity goes into effect.—The Edison Electric Illuminating Company of Boston has declared a quarterly dividend of 1¾ per cent., payable on and after October 26.

Egg Harbor City, N. J.—A company to be known as the Philadelphia Electric Light and Water Company has been organized here with the following incorporators: Henry Kuehne, president; Christian Muller, secretary; Charles Class, treasurer, and George C. Cressy, all of Philadelphia.

Le Mars, Iowa.—Creditors representing $24,700 of the indebtedness against the Le Mars Electric Light and Water Company, have applied for the appointment of a receiver for the concern on the ground that the present management is inexperienced and is not conducting it for the good of the stockholders.

Philadelphia.—The Pennsylvania Heat, Light and Power Company has made arrangements to lease the Edison Electric Light Company of this city for a term of 99 years, the Heat, Light and Power Company agreeing to pay an 8 per cent. dividend on the capital stock of the company for two years and 9 per cent. thereafter.

Norristown, Pa.—The Schuylkill Valley Traction Company, owned by the Shepp brothers of Philadelphia, has sold all its lines in Norristown to a Philadelphia syndicate, the price named being $900,000. The purchasers, it is understood, will make extensive improvements and will also extend the line to other suburban districts and towns.

Fort Wayne, Ind.—The board of public works has granted a franchise to C. Everett to bring his electric street car line from Columbia City and Lake Everett into the city and on Harrison street to the Union Depot. The concession is an important one and assures the building of the line.

Frankfort, Ind.—The electric light plant in this city has been sold by the Citizens' Electric Light Company to the Indiana Natural Gas Company. The plant will remain under the local management. Incandescent lights will probably be added and street lighting put in in the near future.

Emporia, Kan.—J. O. Patterson, a wealthy Chicago capitalist, has made application to the city council here for a franchise for an electric street car line. It is to run east and west, north and south to all parts of the city, and work is guaranteed to be begun within one year and the line to be completed and running within two years.

New Haven, Conn.—The Manufacturers' Street Railroad Company, of which George S. Barnum is president, as under consideration an electric railway plan for connecting the manufacturing plants in the Grapevine Point district with the Consolidated road. It is proposed to use a motor car for hauling the freight cars, the line being intended principally for freighting purposes.

Niagara Falls.—The Carborundum Company received its first power from the Niagara Falls Power Company on the 19th inst., when 1,000 horse-power, transmitted over the copper cables from the great power house, was applied to the manufacture of the new material—carborundum, a cheap and effective substitute for diamond powder and emory. Everything worked satisfactorily.

Chattanooga, Tenn.—The Chattanooga Electric Street Railway, which has been in the hands of the court for some time, is to be sold on December 20 next, and it is understood here that the General Electric Company will be one of the bidders, and that the intention is to consolidate the railway with the electric light company, the latter of which is a G. E. concern. The railway plant is valued at $1,000,000.

St. Louis.—The number of passengers carried by the various street railroads in this city during the third quarter of 1895 was as follows: Cass Avenue and Fair Grounds, 2,469,637; Citizens', 1,825,037; Jefferson Avenue, 317,471; Lindell, 5,489,968; Missouri, 3,810,118; People's, 1,024,575; St. Louis, 3,012,457; St. Louis and Suburban, 2,096,614; Southern Electric, 1,210,403; Union Depot, 6,034,209; total, 27,290,489.

Hagerstown, Md.—The Crawford Bicycle Works of Hagerstown have just completed a horseless buggy, built for the great race on the road between Chicago and Milwaukee which takes place next month. The buggy, which is very light and elegant in structure, will be propelled by electric motors with storage batteries. In the construction hollow steel tubes were used with the design to combine the greatest strength with the least weight. The vehicle has been tried and works successfully.

Duluth, Minn.—A number of Eastern capitalists have effected the consolidation of the Minnesota Canal Company, the Altramonte Canal Company and the Jay Cooke interests, and intend going largely into the business of smelting the low grade iron ore from the Mesaba and Vermillion ranges by means of electricity. On the property that has come into their possession by the consolidation there is water power sufficient to operate the electrical machinery needed.

Hempstead, L. I., N. Y.—The Hempstead Electric Light and Power Company, represented by Arturo Garcia & Co., of New York, have applied to the trustees of Rockville Center for a franchise for lighting privileges. They have also applied to the trustees of Freeport village for the same privileges, and will petition the Hempstead town board for a franchise for the town outside of incorporated villages. They wish to erect a central plant and supply the villages of Lynbrook, Rockville Center, Milburn and Freeport with light and power.

Millbury, Mass.—The stockholders of the Blackstone Valley Electric Railroad have elected the following directors: F. A. Lapham, S. E. Hull, Charles Buck, James H. Ferguson, L. H. Clarke and Herbert A. Ryan, of Millbury; S. M. Snow, of Providence; L. E. Chase, of Wilkinsonville, and E. E. Howe, of Fisherville. The directors elected the following officers: F. A. Lapham, president; Herbert A. Ryan, treasurer; L. H. Clarke, clerk; executive committee: Messrs. Howe, Hull and Ryan; auditing committee: Messrs. Ferguson, Snow and Clarke. The contract for building the road has been awarded to the Worcester Engineering Company.

Milwaukee, Wis.—The "Sentinel" states that the construction of an electric line to Waukesha is beginning to assume shape. It is learned that the Thayer Electric Company has agreed to construct and equip the whole line for $185,000. The line is to form its connections with the Milwaukee & Wauwatosa Motor Railway Company, whose line is to be turned into an electric road. A loop is to be built in Wauwatosa to the county institutions and buildings, and the road is expected to be fully built and equipped for $350,000, which the projectors expect to raise by the issuance and sale of twenty year bonds.—The Badger Illuminating Company will get the contract for street lighting in Milwaukee for the term beginning January 1, there being no competition.

Pittsburg, Pa.—The Ohio Valley Electric Railway Company, just incorporated, proposes to build an electric road to connect with the Pleasant Valley road at Bellevue, and extend the tracks through West Bellevue, Avalon, Ben Avon, Emsworth, Clifton, Dixmont, Glenfield, Agnew, Haysville, Osborne, Sewickley, Quaker Valley, Edgeworth, Shields, Leetsdale, Fair Oaks, Economy, Legionville, Logans, Linmore, Baden, Remington and Conway to Freedom.

Hoboken, N. J.—The common council has granted a franchise to the Hoboken Railroad, Warehouse and Steamship Connecting Company to operate an electric freight railway within the limits of the city. The object of the company is to run a freight line on upper Hudson street and along the river front, so as to give direct communication between the various steamship lines, the warehouses along the river front and the principal railroads.

Fall River, Mass.—The Globe Street Railway has been granted permission to run its cars over Slade's Ferry bridge. The bridge is 1,000 feet long and the right to use it enables the railway company to bring in traffic from Providence, R. I., on the west and from Taunton on the north, and, by connection with the Gee Whiz road it can send a passenger from Taunton through Dighton, Somerset and Fall River, Westport and Dartmouth, through New Bedford to Fairhaven on electric cars.

Salt Lake City, Utah.—The directors of the Salt Lake and Ogden Gas & Electric Light Company have accepted the resignation of the three London directors and filled their places by electing George M. Scott, L. S. Hills and Thomas G. Webber, all residents. The English directors were alarmed at the antagonism of the Salt Lake public toward the company and tendered their resignations, hoping by making it a home concern to put a check to the growing popularity of the new Citizens' Electric Company.

Newark, N. J.—In the course of a few months Newark and Passaic will be connected by a trolley line. To reach the latter city from Newark heretofore it was necessary to go either to New York or Paterson and then take the steam railroads. The new road is known as the Newark & Passaic Traction Company's.—The Consolidated Traction Company has made an arrangement by which the United States Express Company will do business over its various lines in special cars built for the purpose, and six of the cars are now being built in Philadelphia by the J. G. Brill Company for the experiment. They will be roomy box-cars, equipped with a a trolley, and it is proposed to trail a passenger car behind each of them. By means of these cars the express company will be able to do business in every town entered by one of the trolley lines, and it is hoped will pick up considerable business which is now done by individuals who drive express wagons.

Tonawanda, N. Y.—The promised test of electricity as a motive power on the canals was made here on Saturday. A large number of spectators were present and ex-Governor Flower delivered an oration in which he predicted a great future for the canal people when electricity proves its success as a towing power. The system tried was the trolley, by means of a motor car to which a hawser from the boats was attached. Over the experimental mile the system worked successfully. The power was transmitted over a wire from the works of the Niagara Power Company.—It has been announced here that capitalists are about to resume operations and complete an electric railroad from North Tonawanda to Sanborn and Pekin. The route was surveyed and some grading done about two years ago, when funds gave out and the project was dropped. It has now been taken in hand again and will be constructed at once. The line will be about eight miles long.

New Orleans.—After a delay of several months, owing to various reasons, the Villere street cars (electric) have commenced running. The line runs through one of the oldest districts of the city and when the cars were started they created a commotion. There were all sorts of people out to see them, including ancient Creoles, who seldom go away from home; black negroes by hundreds, who live along Villere street and in the intersecting streets; Turks, Italians, black, brown, yellow and all sorts of looking people. They showed wonderful interest in the cars, and one of the officials said that some of them had been sitting in one position watching them since they started in the forenoon and if they had moved at all it was not apparent.—The directors of the Chalmette Railroad Company have accepted the survey of a route for their proposed electric road in the suburbs. The capital stock of the company has been placed at $100,000. The officers and directors are: President, H. T. Beauregard; vice-president, R. V. Ducros; secretary, James Alexander; and Messrs. Albert and J. Estopinal, E. E. Nunez, Sebastian Roy, Christian D. Armstrong, M. T. Ducros and Judge R. T. Beauregard.

St. Paul, Minn.—With the advent of spring, says the "Dispatch," the last cable line will disappear from the St. Paul street car system, and a long-drawn breath of relief will go up from a large territory whose people have been compelled to submit to the trials and tribulations of the erratic and slow-going grip cars. At the time stated the company will replace the Fourth street and Selby avenue cars with an electric line, in furtherance of plans long under contemplation. The difficulty attending the steep grades on the Third street line will be avoided by the adoption of a device which consists of a weight car running in an underground conduit that connects with the surface cars and acts as a balance.—The city and county of Ashland, it is said, propose to give $200,000 to aid the scheme of building an electric road between this city and Ashland. The "Pioneer Press" says the purpose is to make Ashland with its splendid harbor, the entrepot upon Lake Superior of the great traffic of the two cities instead of Duluth. The advantages claimed for it over the Duluth route is that the railroad from Ashland to St. Paul would be only twenty-eight miles longer than the shortest line to Duluth, while it would save ninety miles of navigation, back and forth, or 180 miles in all, and afford an unequaled harborage.

PERSONAL.

Among our out-of-town visitors last week were Mr. J. R. Rhotehamel, president of the Columbia Lamp Company, Charles E. Gregory, of Chicago, and Geo. D. Rosenthal, of St. Louis.

It is reported from Chicago that Mr. O. W. Meysenberg has retired from the Siemens & Halske Company in order to devote all his energies to the affairs of the Wells & French Company.

Messrs. F. L. Babcock, of Cuyahoga Falls, David Starr, of Montreal and Charles Burns, of Rochester, were among the out-of-town hustlers in the city this week.

COMMERCIAL PARAGRAPHS.

We have received from Mr. Chas. Wirt, corner Ludlow and 31st streets, Philadelphia, Pa., a copy of catalogue of the Wirt Brush, which contains practical information interesting to engineers, drawn from an extended experience *and intimate* acquaintance with the practical provisions under which dynamos are worked.

Fred. M. Locke, Victor, N. Y., manufacturer of the well-known Indestructible High Potential line material, has just closed three large contracts for his Porcelain Insulators and Steel Pins to be used on long-distance transmission *lines.*

The superior qualities of the Partridge Motor Brush have been known so long to the street railway trade that an *elaborate* exhibit at the Montreal Convention was not really necessary. Mr. J. S. Speer, secretary of the Partridge Carbon Company, was there however, and the results that have followed the Convention in the shape of *increased* orders clearly show what a good man can do with a good thing and still have a good time.

Lamps may come and lamps may go, but the old Sawyer-Man lamp retains all its claims to popular favor which made it such an important factor years ago. It is to-day as good as ever, and that is saying alll that is necessary.

New Fort Wayne Book.

One of the most elaborate trade publications recently issued by any manufacturer of electrical apparatus is the "Complete Catalogue of the Wood Systems of Electrical Machinery and Apparatus for Light and Power" now being distributed by the Fort Wayne Electric Corporation. This book consists of 132 pages. to the embellishment of which the arts of the engraver and printer have been applied with most pleasing results. The descriptive matter is brief, but it is supplemented by a liberal use of illustrations reproduced from photographs.

The details of the Wood apparatus are shown and described with clearness and conciseness, so that every reader, however much he may lack in practical knowledge, will have an intelligent comprehension of the subject after a study of this Catalogue.

Western Electric's New Factory.

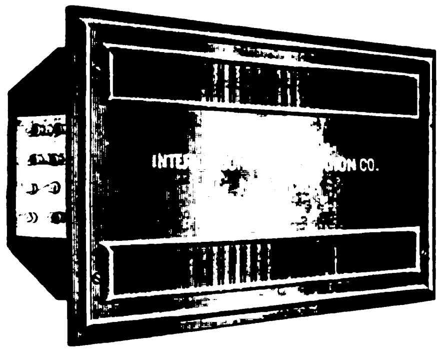
The Western Electric Company is makinganother extensive addition to its Chicago factory. The new building is at West Congress and Jefferson streets, in the rear of the present factory. When this is completed the works of the Western Electric Company will cover 104,000 square feet of space.

The new factory building fronts on Jefferson street and is 180 feet long by 50 feet wide and will be eight stories high. It is fire-proof, of steel construction, built to accommodate a traveling crane with a span of 25 feet, which will run the entire length of the building and takes up the basement and first story. This will be used for handling the heavy castings used in the new types of dynamos and motors. It is expected the building will be finished by January 1, 1896.

A New Electric Car Heater.

The Interior Conduit and Insulation Company of New York have introduced this season an Electric Car Heater which embodies great improvements in this class of apparatus.

A much higher efficiency has been obtained in these heaters than in other machines which have heretofore made their appearance, and this economy of operation is by far the most important factor which is considered by any railway ompany. All the electric energy absorbed by any electric heater is converted into heat units, and it has in consequence been assumed by many that electric heaters are of necessity of equal efficiency, but this is not the case. It is not sufficient merely to create heat, but also to utilize it to he best advantage, and in order to do this it is imperative hat the heat should be distributed and circulated where it needed, and as fast as it is generated. In other heaters, large proportion of the heat produced has been non- fective for any useful purpose owing to lack of proper stribution, as most of the air current passes around the ils leaving the heat dormant, and the case of such heats absorbs a large quantity of heat, so much so that in some stances fire has been caused, endangering the lives of passngers. Such machines require from six to twelve amres at five hundred volts to sufficiently warm the car.



New Electric Car Heater.

In the heater manufactured by the Interior Conduit and sulation Company, a continual circulation of air is mainined. All the air passes through the coils, and all the at generated is carried off and distributed into the body the car, the case of the heater remaining perfectly cool. here is absolutely no waste, and consequently a much gher degree of efficiency is obtained than has hitherto en practicable. These heaters are thoroughly well made, at in appearance, easily installed, and are amply guaranted.

"Roll-Drop" in Pen and Ink.

The Forest City Electric Company, Cleveland, Ohio, have ued a very handsome booklet devoted to their already ll-known "Roll-Drop" Commutator Bars. Considerable ce is devoted to data concerning the numerous forms d sizes of Commutator Bars now in commercial use rticularly those employed on railway generators and motors. The methods of manufacture of "Roll-Drop" Bars are described in a brief and catchy manner, and aptly illustrated with clever pen sketches. The book is for distribution and should be in the hands of every commutator user.

Four New Turbines for Niagara.

The Niagara Falls Hydraulic Power and Manufacturing Company have recently contracted with James Leffel & Company, of Springfield, Ohio, for four of their Improved Double Discharge Horizontal Shaft Water Wheels, to be of eight thousand horse power capacity under a maximum head pressure of 218 feet, which is far the highest head under which turbines of large capacity have ever been applied in this country or elsewhere. These wheels will drive eight electrical generators, which will be connected direct to the horizontal turbine shafts without gears or belting, the wheels and generators all running in vertical planes. This is the second large order for turbines built by James Leffel & Company for Niagara Falls, there being already several of this make of wheel, each of 1,200 horse power, in daily operation in the Cliff Paper Company mills, located at the cliffs, near the tunnel. This water wheel company is also building four of their Cascade wheels for one company, to be operated under 730 feet head; part of the power to be electrically transmitted by connecting the wheel shaft directly to the generators. The Cascade wheel is, however, essentially and entirely different in construction and operation from the turbine, being in principle an impulse and reaction wheel. This Cascade wheel plant will have an aggregate capacity of six hundred horse power.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

(Issued by the Washington Carbon Company.)

NOVEMBER, 1895.

Date.	Light.	Date.	Exting.

BUSINESS HINTS.

Allegheny, Pa.—Charles Lockhart has begun the building of a new business block, 6 stories, on Penn ave., to cost $50,000; Architect W. S. Frazer.

Baltimore, Md.—The plans for a ten story apartment house, to be erected at northeast corner of Cathedral st. and Mt. Vernon Place, have been completed.

Brooklyn, N. Y.—Moller & Bro. & Co., will erect 2 four story apartment houses on north side of South 9th st., east of Bedford ave., to cost $27,000.

Buffalo, N. Y —Architect H. H. Little is preparing plans for the new six story building of the Buffalo Drug, Paint and Glass Co., to be erected on Swan st., near Ellicott, to cost $300,000 ... The 20th Century Club house will be erected on Delaware ave., just below Temple Beth Zion; Architects Groon & Wickes.

Macon, Ga.—Charles B. Moling, of Columbus, O., who recently purchased the Paterson plantation near Macon, is interested in the erection of a modern hotel at this place, to cost $250,000.

Newport, R. I.—Robert Goelet, 9 West 17th st., New York City, is said to be planning to erect the finest villa in Newport, on the Cliffs.

New York City.—The American Society of Civil Engineers have purchased a plot on south side of 57th st., between 7th ave. and Broadway, and will erect a club house on the site....George J. Schreiner and George Fennell, of 101 West 121st st., will erect 4 five story brick flats and stores, northwest cor. of 108th st., and Madison ave., to cost $79,000.

Ottawa, Ill.—The Western Cottage Piano and Organ Company will erect a $30,000 factory, after plans prepared by W. A. Youmans & Bros., 706 Tacoma Building; the factory will be fitted with a dynamo, electric fans, etc.

Philadelphia, Pa.—Plans have been drawn by Bailey & Truscott for the proposed new building for Cyrus H. K. Curtis, to be erected at 6th and Walnut sts; the building will be nine or ten stories high.

Portland, Me.—The Hooper Building, cor. of Pearl and Congress sts., will be converted into a variety theatre.

Washington, D. C.—Mrs. General D. D. Colton, formerly of San Francisco, Cal., has had plans made for a handsome and expensive home on Connecticut ave. between R and S sts. Northwest, from designs drawn by C. B. Keferstein; it will be lighted by electricity and gas and heated by steam.

Whatcom, Wash.—The Normal School trustees have accepted the plans prepared by Skillings & Conner, of Seattle, for gymnasium, assembly hall, etc.; the building will be provided with electric clocks and other electrical equipments.

ELECTRICAL PATENT RECORD.

Letters Patent Issued October 22, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

548,371. Electric Locomotive. Walter H. Knight, New York, N. Y. Filed June 15, 1888.

548,389. Three-Wire Electric Railway. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed Aug. 8, 1895.

548,481. Underground Conduit for Electric Railroads. Richard Uren, Hancock, Mich. Filed May 10, 1894.

548,504. Combined Electric and Cable Railway. Gardner E. Beach and Morris J. Kern, San Francisco, Cal. Filed Aug. 1, 1892.

548,514. Underground Conduit System. Hiram C. Burk, Cleveland, Ohio. Filed Feb. 28, 1893.

548,599. Electric Street-Car Controller. Gustaf Valley, Cleveland, Ohio, assignor to the Steel Motor Company, same place. Filed Dec. 5, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

548,369. Electric Desk-Light. Walter R. Kinsman, Arlington, N. J., assignor to Thomas I. McLeod, New York, N. Y. Filed Oct. 14, 1893.

548,413. Electric-Arc Lamp. Thomas E. Adams, Cleveland, Ohio, assignor to the Adams-Bagnall Electric Company, same place. Filed July 8, 1895.

548,414. Electric-Arc Lamp. Thomas E. Adams, Cleveland, Ohio, assignor to the Adams-Bagnall Electric Company, same place. Filed July 10, 1895

548,574. Phosphorescent Electric Lamp. Daniel McF. Moore, New York, N. Y., assignor to the Moore Electrical Company, same place. Filed Jan. 3, 1895.

548,575. Phosphorescent-Electric-Light Condenser and Accumulator. Daniel McF. Moore, New York, N. Y.; assignor to the Moore Electrical Company, same place. Filed Jan. 24, 1895.

548,576. Phosphorescent Electric Lighting by Interruptions. Daniel Mc F. Moore, New York, N. Y., assignor to the Moore Electrical Company, same plaee. Filed Jan. 24, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

548,217. Method of and Apparatus for Rectifying Alternating Currents. Jules E. Neher, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Aug. 7, 1893.

548,230. Method of and Means for Temperature Adjustment for Inductance-Coils. Oliver B. Shallenberger Rochester, Pa. Filed April 15, 1895.

548,266. Automatic Switch for Electric Transformers. Anthony G. New, London, and Arthur J. Mayne, Woking, England, and Richard N. Lucas, Galway, Ireland. Filed June 25, 1894.

548,280. Electric Stop Mechanism. William M. Wood and James C. Miller, Elmira, N. Y. Filed June 7, 1894.

548,383. Magnetic Separator. James D. McKinnon, Portland, Oreg. Filed April 16, 1895.

548,388. Regulating Electric Motors. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed July 22, 1895.

548,400. Regulator for Alternating Currents. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 18, 1895.

548,401. Electric Motor. Imle E. Storey, Hornellsville, N. Y., assignor to the Storey Electric Drill and Power Company, of Colorado. Filed Jan. 28, 1893.

548,402. Electric Motor. Imle E. Storey, Hornellsville, N. Y., assignor to the Storey Electric Drill and Power Company of Colorado. Filed Jan. 28, 1893.

548,406. Dynamo-Electric Machine. Elihu Thomson Swampscott, Mass., assignor to the General Electric Company of New York. Filed March 29, 1895.

548,448. Controller for Electric Motors. Daniel J. McLane and George W. McClintock, Quincy, Mass. Filed May 25, 1895.

548,511. Method of Converting or Transforming Periodic Electric Currents to Obtain Constant Effective Intensity or Voltage. Paul Boucherot, Paris, France. Filed Dec. 10, 1892.

548,589. Electric Stop-Motion for Engines. Louis St. Peter, Springfield, Mass., assignor of two-thirds to John D. Millea and Thomas D. Millea, same place. Filed March 1, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

548,22[illegible]. Telephone-Receiver Support. Isidor J. Kusel. St. Lous, Mo. Filed Feb. 18, 1895.

548,227. Telephone-Exchange Apparatus. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 5, 1892.

548,228. Apparatus for Telephone-Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 28, 1895.

548,229. Keyboard Apparatus for Telephone-Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 7, 1893.

MISCELLANEOUS.

548,176. Magnetic Ore-Separator. Charles G. Buchanan, Brooklyn, N. Y. Filed Feb. 13, 1895.

548,265. Hydrostatic Electric Amalgamator. James D. McKinnon, Portland, Oreg. Filed Dec. 14, 1894.

548,282. Electromechanical Lock. William W. Alexander, Kansas City, Mo., assignor to the Gill-Alexander Electric Manufacturing Company, same place. Filed Nov. 15, 1889.

548,320. Manufacture of Stereotype-Plates. Victor Lowen Dahl, Stockholm, Sweden. Filed Oct. 11, 1894.

548,331. Magnetic Brake Oakley S. Walker, Worcester, Mass. Filed Feb. 20, 1895.

548,396. Electric Cigar-Lighter. Friedrich W. Schindler-Jenny, Kennelbach, Austria Hungary. Filed Feb. 19 1894.

548,415 Dry Battery. Frank M. Archer, New York, N. Y., assignor to Siegfried Silberberg, same place. Filed Dec. 15, 1890.

548,419. Electric Metering Apparatus. William S. Barstow, Brooklyn, N. Y. Filed April 6, 1895.

548,435. Electric Block-Signaling Instrument for Railways. Arthur C. Fraser, Brooklyn, N. Y. Filed Feb. 26, 1891. Renewed March 26, 1895.

548,467. Electric Meter. William H. Scott, Norwich, England, assignor to Laurence Scott & Co., Limited, same place. Filed Nov. 4, 1892.

548,469. Automatic Block System. Judson Shoecraft Harveyville, Kans., assignor of one-half to Orison C. Miller, Wabaunsee County, Kans. Filed March 27 1895.

548,509. Electromagnetic Brake. John L. Black, St. Louis Mo., assignor to the St. Louis Electric Brake Company East St. Louis, Ill. Filed May 9, 1894.

548,510. Electromagnetic Brake. John L. Black, St. Louis Mo., assignor to the St. Louis Electric Brake Company same place. Filed April 13, 1895.

THE TELEPHONE WORLD.

THE STANDARD AT RICHMOND, VA.

Some Light Thrown on the Methods of "The Boys in the Real Pot."

At no place has so spirited a contest for a telephone franchise taken place as at Richmond, Va. Some weeks ago applications for a franchise were made by the Richmond Standard Telephone Company and the Home Telephone Company. The former is one of the many sub-organizations of the Standard Telephone Company of Arizona, 253 Broadway, New York, and elsewhere. The Home Company is composed of Richmond and Baltimore capitalists, the Board of Directors being J. N. Cullingworth, J. D. Patton, S. W. Travers, P. Whitlock, E. A. Catlin, Junius A. Morris, J. D. Crump, J. J. Montague, F. B. Hubbell, James Russell and W. J. Atkinson.

To the City Council the Standard representatives made plausible, though extravagant, statements as to the accomplishments of the Standard Company and the capabilities of their "only perfect" telephone. They promised to establish one of their numerous factories in Richmond if they were given the franchise. The Home Telephone Company stated that they would use the well known "Mason" telephone, manufactured in Richmond by the Mason Telephone Company, and already in use in a large number of exchanges. The City Council appointed a committee consisting of W. E. Cutshaw, City Engineer, and W. H. Thompson, Superintendent of Fire Alarm, to make a test of the instruments of the competing companies. As a result of the test the committee reported that they "are led to believe the Standard to be the better 'phone." The following letter gives some interesting facts concerning the test made by this committee:

To the Editor of ELECTRICITY.

DEAR SIR: I have had an opportunity to become fully conversant with the methods which the Standard Telephone Company employ, as laid down in their circular "To the Boys in the Real Pot" In this city, I submitted 'phones of my manufacture constructed for ordinary exchange service, as well as for long distance service, to the committee, who tried them in competition with one of the 'phones which the Standard Company claims to be manufactured under their patents. Of these patents, however, they refuse to give any information. They refused to allow any one to see the inside of their transmitter excepting the two men who were appointed on the committee. These men were not experts in telephone matters, and did not know a long-distance Bell telephone from any other ordinary transmitter. The examination of the instruments was made in a star chamber session, with no one present excepting the representative, of the Standard Company and the two experts who composed the committee.

The writer accused the representatives of the Standard Company of having on exhibition a regular long-distance American Bell telephone, and they, being aware that he was right, refused to allow the internal construction of the instrument to be seen by myself or any other expert who was conversant with such matters. Before the committee made its decision, I took into the room a regular long distance Bell instrument and showed the committee the internal arrangements of the same. In the formal report of the committee they recognized the fact that the instrument which the Standard Company had before them "approaches more nearly 'phones now in use" by the American Bell Telephone Company, as they say, than the 'phone offered by the writer. The committee made their report knowing that I had 'phones in use all over the country. I read testimonials to them from people who are using my 'phones and who speak in the highest way of them, while the Standard Company had no testimonials whatever to offer and could not name a single place where their 'phones were in use in any kind of service, excepting on exhibition lines and under their own care.

The action of the Standard people in refusing to allow any disinterested expert, or a man of national reputation and above suspicion, to examine into their 'phone, puts them, in the mind of any fair man, in a very questionable light. I am ready at any time to submit the instruments and devices on which I hold patents to any test which they will submit their 'phones to, and not only to do that, but to allow any one to examine into their merits, feeling confident that they will stand any test. I am inclined to believe that certain people have profited by the hints contained in the letter of the Standard people "To the Boys in the Real Pot."

I appreciate very much the stand you are taking. I speak for myself individually, because I am directly interested in the devices which I am putting on the market. Wishing you success, I remain yours truly,

G. S. MAXWELL.

Richmond, Va., October 18, 1895.

After the committee had made its report Mr. Maxwell, who is general manager and electrician of the Mason Telephone Company, published a card in the local papers of Richmond offering a reward of $100 provided he could not prove to any committee of disinterested experts that the so-called Standard telephone "is either a Bell long-distance telephone or a rank infringement of the Watson, Rooseveldt and other patents controlled by the Bell Telephone Company." He offered $10 reward for the number of any patent owned by the Standard Company, and $10 reward for proof that the Standard Company have a telephone exchange in operation anywhere in the world. The challenge has not been accepted by the Standard Company, but John C. Robertson, president, sent a circular letter to all the members of the City Council, making, among others, the following statements:

. . . The Standard Telephone Company has never issued any such circular as that quoted by our opponents from ELECTRICITY, a journal of unsavory reputation which is not recognized in the electrical profession; nor has it made any suggestion of corrupt dealings with councils.

The Standard Telephone Company does not use or propose to use the Bell telephones or any infringements on their patents, but owns its own patents, lists and numbers of which have frequently been proclaimed and published.

The Standard Telephone Company has its own factory now in active operation in New York, and is establishing several now in the North.

The Standard Telephone Company will, if we are granted a franchise here, establish a factory in Richmond for the supply of at least six Southern States.

I have already published the names of a dozen or more gentlemen of national reputation and great wealth, whose connection with the active management of the Standard Company should be a sufficient refutation of the calumnies so industriously circulated.

Finally, I hope and believe that the Richmond Standard Telephone Company will receive the city's franchise for the following reasons, all of which are proven facts:

1. It has the best telephone for local service.
2. It has the best and only long-distance 'phone.
3. It is backed by the strongest company, and the only one able to cope with the Bell monopoly.
4. It will employ the largest number of skilled laborers.
5. It will bring here *and keep here* the most money.

The report of the expert committee above referred to does not settle the question of franchise. The report has yet to go to the City Council.

A Railway Telephone.

Superintendent E. B. Baker of the Southern New England Telephone Company has constructed a device for telephoning from moving trains. One part of the apparatus consists of what is called a "hanging set," to be carried on every baggage car and caboose. If a train comes to a standstill through accident or otherwise the hanging set, consisting of spliced rods with a cross-arm at the top, is dropped on the wires at the pole line alongside the track, thereby establishing telephonic connection with the despatcher's office.

"Doing It Well."

To the Editor of ELECTRICITY.

DEAR SIR: Your article on "Speculative Telephone Enterprises," in last week's issue, has attracted the attention it deserves in Richmond at least. The events there, and letters received from telephone companies elsewhere, it seems to me, tend to confirm the position you take in your article, that the Standard Telephone Company is one of the worst swindles of the century, and that you deserve the thanks of every business man in the country, especially those engaged in the telephone business, for your fearless exposure of their methods. You are doing a magnificent work and doing it well. Respectfully yours,

W. J. ATKINSON.

Baltimore, Md., October 22, 1895.

The New York and New Jersey Telephone Company have acquired the right of way along the shore front from Point Pleasant to Atlantic Highlands, N. J., for a new telephone line, with three additional exchanges at convenient points along the coast. Beside touching all the sea coast towns, this line also will tap Keansbury, Port Monmouth, Redbank, Keyport, South Amboy and Perth Amboy, N. J., and go across the Kills by cable to Staten Island and thence into New York.

The Claiborne Telephone Company has been organized at Port Gibson, Miss., with Jacob Bernheimer, president; Chas. A. French, vice-president; Dr. W. Reduse, secretary, and William Cahn, treasurer. The object of the company is to connect all the towns of the county with Port Gibson, the county seat.

The Automatic Telephone and Electric Company of Chicago has brought suit for $50,000 damages against H. S. Bower, of Bloomington, Ill. Bower was instrumental in organizing the Home Telephone Company in Bloomington. The plaintiff claims that Bower contracted for its automatic telephone switchboard, and instead of taking this device installed the old-fashioned board.

A meeting of delegates of the several commercial organizations of Buffalo was held on the 21st inst., at which it was decided that a letter should be sent to each candidate for the Assembly and the Senate asking if he were in favor of a bill similar to the Gerst-Persons telephone bill which was submitted to the Legislature last year.

The Hyde Park District Telephone Company has commenced laying conduits for its telephone service in the village of Hyde Park, Chicago. The company is an independent concern, and is backed by capitalists from Springfield, Ill.

Money has been subscribed and a company organized for the construction of a telephone line from Eastland, Tex., to Breckinridge, via Gunsight. Work will begin immediately.

Frank S. Vincent, representing the Chase Telephone Company, has secured a fifteen-year franchise in Petoskey, Mich.

The Luzerne County Telephone Company is being organized to operate in all of the cities and towns of Luzerne County, Pa. Sol Hirsch, of Wilkes-Barre, is promoting the enterprise, which is said to be backed by New York capital.

The Elko Telephone Company, Elko, Ga., have connected Elko with Perry and Fort Valley.

The American Telephone and Telegraph Company has asked for permission to enter Richmond, Va., with its long-distance lines.

New Companies Incorporated.

The Altoona Phœnix Telephone Company of Altoona, Pa., recently incorporated, will operate a telephone plant in the counties of Blair, Huntingdon, Cambria, Clearfield and Bedford, Pa. The capital stock of the company is ·15,000. The officers are: H. Price Graffius, president; A. V. Dively, treasurer; John M. Hamer, general manager, and Willard P. Beardsley, secretary. Directors: H. Price Graffius; A. V. Dively; John Flanigan, Hon. J. D. Hicks and Wm. A. Ambrose, all of Altoona, Pa.

Simplex Interior Telephone Company, Cincinnati, O. Capital stock, $5,000. Incorporators: Walter L. Bradshaw John Seymour, Emile Koel, Robert G. Stevenson and James McClain.

The Vacaville and Winters Telephone Company, Vacaville, Cal. Capital stock, $5,000. Directors: E. R. Thurber T. K. Buck, William H. Buck, F. B. McKevitt, Vacaville; Henry Bruick, Winters.

The Lincoln and Knox Telegraph and Telephone Company, Waldoboro, Me.—to own, construct, maintain and operate lines of telephone or telegraph. Capital stock, $3,000. Officers; George Bliss, president; Lincoln N. Kennedy, treasurer.

The Home Telephone Company, Jersey City, N.J.—to erect and operate telephone lines in all the cities and towns of Hudson county, New Jersey. Capital stock, $300,000. Incorporators: Ernest J. Ford, P. Justus Atkinson and George N. Atkinson.

The Automatic Telephone Exchange, Detroit, Mich.—to manufacture and sell an automatic telephone exchange. The company has a nominal capital of $1,000,000, represented mainly by the value put upon its patents. The officers and stockholders are: Charles A. Gates, of Saginaw, chairman; William Rebec, of Saginaw, vice-chairman; Charles P. Cavin, of Saginaw, treasurer; Arthur B. Harford, of Detroit, secretary and general manager; Malcolm McGregor, of Detroit, treasurer.

INCORPORATIONS.

The Munson Electric Conduit Company, Davenport, Iowa—to manufacture, buy and sell and do a general business in goods and appliances and construct electric railways. Capital stock, $10,000,000. Promoters: John H. Munson, James E. Merritt, Wm. F. Robert.

The Evanston Electric Railway Company, Chicago, Ill—to conduct, lease or otherwise acquire horse, dummy and electric street railways; maintain and operate same. Capital stock, $200,000. Promoters: Andrew Crawford, Thos C. Milsted, Park E. Simmons.

The Victor Electric Company, Chicago, Ill.—to manufacture and deal in electrical and mechanical machinery and devices and to do all kinds of electrical work. Capital stock, $2,400. Promoters: C. F. Samms, J. B. Wantz, E. P. Vickers.

The Big Four Electric Company, Chicago, Ill.—to manufacture, buy and sell, lease or otherwise deal in electrical apparatus, devices and machinery, and light, heat and power. Capital stock, $200,000. Promoters: Henry D Ames, Wm. H. Brown, Louis K. Gillson.

The Ohio Valley Electric Railway Company, Pittsburg, Pa.—to build a railway in Allegheny County, Pa. Capital stock, $25,000. Promoters: Wm. T. Lindsay, Henry E Lineaweaver, Pittsburg; Edgar C. Gerwig, Allegheny.

The St. Mary Mining Company, Spokane, Wash.—to do a mining and real estate business; erect and operate electric light and power plants. Capital stock, $500,000. Promoters: C S. Voorhees, J. L. Willson, R. H. Voorhees, J. M Burke, T. E. Jefferson, H. L. Willson.

The Lima and Piqua Electric Street Railroad Company, St. Mary's, Ohio—to build and operate a street railroad between Piqua and Lima, O., to be operated by steam, horse, electric or other motive power, and to furnish light, heat and power. Capital stock, $9,000. Promoters: B. C. Faurot, D. W. Jay, D. Armstrong, Wm. H. Hartman, S. W McFarland, Edward Burns.

The Union Power Company, Cleveland, Ohio—to generate and distribute from one or more centers electric or other power for motive, electro-chemical, welding, heating and other purposes. Capital stock, $50,000, Promoters H. N. Chamberlain, J. Henry White, F. C. Phillips, Geo. C Wing, Morris S. Towson.

The Chicago Water Heater Company, Chicago, Ill.—to manufacture and sell heaters, ranges, stoves and any and all kinds of machinery, utensils and apparatus for heating buildings, cars and other structures by means of water, steam, air, electricity and other methods. Capital stock $10,000. Promoters: B. W. Sherman, Samuel E. Hibben, John L. Jackson.

The Lucas Electric Construction Company, Baltimore, Md.—to deal in all kinds of electrical supplies. Capital stock, $2,000. Incorporators: J. Clarence Lucas, Ridgeway Moseman, Chas. E. Burgar, Wm. D. Wilson, Jr., and Wm. M. Burgar.

Gray's Electric Railway Supply Company, Saco, Me.—to manufacture, rails, cars, apparatus for electric and other railways, etc. President, Robert Johnson; treasurer, R. Powers, both of Boston, Mass.

The Dansville Gas and Electric Light Company, Dansville, N. Y. Capital stock, $25,000. Directors: W. W. Cramer, W. T. Spinning, Charles H. Rowe and others of Dansville.

Wicke & Reinhardt Car Fender Company, Brooklyn, N.Y.—to manufacture car fenders. Capital stock, $10,000. Directors: Philip Reinhardt, O. A. Wicke, George E. Koch, F. W Grau, and R. Koch of Brooklyn.

The National Coal Mining Company, Portland, Ore.—to do a general mining business, acquire and conduct hotels, do a general improvement business, construct and equip railroads, telegraph, telephone and electric lines, etc. Capital stock, $220,000. Incorporators: J. B. Parker, F. M Batchelor, J. S. Stephenson, G. Balsamy, R. A. Reid and T. A. Edwards.

Hot Springs, Va.—President Ingalls of the Big Four and Chesapeake & Ohio Railroads has received plans for a $100,000 hotel to be built at Hot Springs.

Jersey City, N. J.—Edward Schroeder will build two handsome five story flats, southeast corner of Jersey ave and 9th st ... Ex-County Clerk Dennis McLaughlin is about to expend $40,500 in the erection of four five story brick flats, two of which will face West Hamilton Place, near 9th st

The Sac City Electric Company, Sac City, Iowa—to erect, establish and maintain a plant to furnish customers light, heat and power. Capital stock, $15,000. Promoters: L. C Early, Asa Platt, D. E. Hallett, E. W. Bailey, J. E. Robbins W. Cheney, J. Y. Campfield, D. I. Dixon, C. W. Marey, Geo A. Martin, Geo. A. Miller, J. W. Wilson, Phil. Schaller.

EDITORIAL NOTES.

When the "Kiting" Epoch Will End. If further confirmation of the statements made in these columns touching the disastrous results of over-capitalization of electric railways were needed, none could be stronger than the declarations made by Col. H. G. Prout, editor of the *Railroad Gazette*, in an address which is reported elsewhere in this issue.

Col. Prout is a well posted and observant student of progress in the transportation world. Conservative, as most steam railroad men are, he is not oblivious to the fact, nor does he hesitate to admit it, that the electric motor has made a formidable invasion into the field hitherto exclusively occupied by the locomotive. Like all other well-informed engineers, Col. Prout recognizes the limitations in the application of electricity to lines of railroad now operated by steam, yet he is aware that the time has fully come when practical railroad men must needs give careful consideration to the problem of improved suburban and interurban service.

Some of Col. Prout's suggestions as to the best methods to be employed by railroads in order to retain or to increase their local traffic within suburban zones, are eminently practical, and we doubt not that the enterprising managers of roads which serve large centers of population will be quick to adopt them.

In this connection it is encouraging to note that railway and electrical interests are co-operating more heartily than ever before in an effort to reach a solution of the rapid transit problem. This bodes no ill to the electric motor.

It is not from a professional engineering standpoint alone that Col. Prout's view of the situation is clear. His opinions of the commercial side are as sound as they are vigorously expressed. He says:

> There is, however, a set of conditions at work which will change the situation of the present electric railroads a good deal before long. Up to the present time it has been, and still is, easy to finance them, because rail mills and electrical manufacturers are glad to help float the bonds of new electric railroad projects; the public is credulous and investors look for great profits. We are, therefore, in the midst of the "kiting" epoch of electric railroads, when bonds which are sold to-day pay the interest on the bonds sold last month or last year. But, naturally, this situation must come to an end before long.

The end will not come so long as the electric railroad "promoter" is permitted to ply his iniquitous trade; it will not come so long as roads costing less than $15,000 per mile are capitalized at $250,000 or at even $95,000 per mile; it will not come so long as bonds are issued to pay for the worthless stock of consolidated companies, or to pay interest on bonds already issued, or to pay dividends on watered stock.

It *will come* when the electric railroad business is as carefully, as honestly, and as conservatively managed as any other legitimate business.

Then, but not till then.

* * *

Safety in Electrical Wiring. In the electrical lexicon of Captain William Brophy there is no such word as "shoddy." He has always maintained, with an earnestness born of a firm conviction, that the highest factor of safety in the electrical wiring of buildings can be obtained only by the use of the best material, installed by honest, capable workmen. Captain Brophy's long and varied experience in the field of electrical inspection, coupled with the thorough investigation of the many problems which have come to his official and individual notice, eminently qualify him to speak with authority. In his remarks upon the "Defects in Electrical Wiring," published elsewhere in this issue, there is perhaps little that is new, unless, indeed, it be new or strange to insist that good work *must* be done in order to insure the nearest approach to perfect safety.

That the application of electricity to lighting and power purposes has been somewhat restricted is due, in no small measure, to the use of faulty material, carelessly installed. The degree of excellence which is now admitted to be essential in all material used in electrical installations has been attained only after years of experiment and improvement. There was, therefore, a reasonable excuse to be offered for the employment of such material as underwriters' wire for interior work, as was common six or eight years ago. But the absence of interior conduit, high grade insulated wires, and other appliances as now perfected, can never be urged as a justification for stringing 110 volt wires to a damp ceiling by bell tacks, or attaching them to gas fixtures without cut-out or insulating devices, or making a service tap with both sides of a circuit run through one hole in a window casing, or any other of the practices which unskilled workmen employ even at this day.

Happily for the increasing growth of the electrical industry, and the more certain stability of the trade, the improvements in devices and material and the growing demand of architects, engineers and owners for the best, tend more and more to drive the shoddy goods, the shoddy contractor and the shoddy workman out of business. Captain Brophy notes this encouraging sign of the times, and while he feels warranted in expressing the "firm belief that the transmission of electric energy and its conversion into light, heat, sound and articulate speech, or its reconversion into motive power, can be accomplished with nearly perfect safety," he is convinced that this condition can be approximated only by the use of the best material, honestly installed under skilled direction and according to intelligent plans.

Such a consummation will demand of the manufacturer his best product, of the architect and engineer accurate knowledge, and of the contractor something more than a desire for big profits.

Fortunately these qualifications already exist, but unfortunately they are too rarely combined.

* * *

"What's In It For Me?"

Under this heading there was published in ELECTRICITY for October 16 an article devoted specially to the subject of payment of commissions by manufacturing companies to purchasing agents—in plain English bribery. The article, to put it mildly, attracted considerable attention. We showed as conclusively as was possible in the space used the evil effects of the system, by specific examples; first, that the employer of the purchasing agent was robbed by the practice, and, second, that manufacturers who refused to pay commissions suffered an injustice at the hands of the purchasing agent and his co-conspirators. In the entire article there is not one word which we wish to retract. ELECTRICITY stands first, last and all the time for purity in business methods.

Among the companies charged with having paid bribes to L. H. McIntyre of the People's Traction Company, Philadelphia, was the Peckham Motor Truck and Wheel Company of this city. It was also charged that, under the same influences, Brill trucks, purchased by the board of directors in spite of McIntyre's protest, had been discarded after a few months of service, at great loss to the railway company and injury to the business of the Brill Company.

It was also stated, *upon information furnished to* ELECTRICITY *by a director of the People's Traction Company*, that in this period the Brill trucks had cost nothing for repairs, and that the Peckham trucks had cost a good deal for repairs.

In an advertisement in the current issue of the *Street Railway Journal* the following letters are printed:

> THE PECKHAM MOTOR TRUCK AND WHEEL COMPANY,
> New York, October 23, 1895.
>
> GENTLEMEN: Referring to the recent article in a so-called electrical journal, distributed at the recent Convention at Montreal, which referred to our trucks in use on the People's Passenger Railway of Philadelphia, I beg to call your attention to the enclosed letter just received from the President of the People's Passenger Railway Company, referring to this article, and which explains itself. This letter is our reply to the article referred to. Very truly yours,
>
> E. PECKHAM, President.

> PEOPLE'S PASSENGER RAILWAY COMPANY,
> Philadelphia, October 22, 1895.
> Peckham Motor Truck & Wheel Company, New York.
>
> DEAR SIRS: We have seen the notice in ELECTRICITY relative to your sales to this company, and our action in regard to the Brill trucks. The statement is made in ELECTRICITY that "At the end of ten (10) months, not one dollar had been spent for repairs on the Brill trucks, and the Peckham trucks had cost this company nearly their original purchase price in rebuilding.' The situation is exactly the reverse. That is to say, the Peckham trucks cost us comparatively nothing, while the Brill trucks proved much more expensive in maintenance. We write you this in justice to the construction of your work and our experience with the trucks under severe conditions. We think it is but justice to you to make this statement. Yours very truly,
>
> (Signed) WILLIAM H. SHELMERDINE, President.

Notwithstanding all this, we maintain our original assertion, and will take pleasure in making the history of the whole deal, with side lights on other deals, a matter of legal record.

It is proper that the following letter from the J. G. Brill Co. be given equal prominence with those of Messrs. Peckham and Shelmerdine, and to state that the latter was not *president* of the People's Traction Co. when this purchase of trucks was made.

> PHILADELPHIA, November 1, 1895.
> EDITOR OF ELECTRICITY,
> 6 Park Place, New York City.
>
> DEAR SIR: In the advertisements in the *Street Railway Journal* for November there is a page from the Peckham Motor Truck and Wheel Company which contains a letter purporting to have been written by Mr. Shelmerdine, president of the People's Passenger Railway Company, which flatly contradicts the statement in your article in issue of October 16th as to the relative performance of the Brill trucks and the Peckham trucks on the road of that company. This letter does not contain a true statement of the facts, and its writer has evidently been deceived. Mr. Shelmerdine was not in that position when the matter referred to happened, and has evidently had his information from the assistants and appointees of McIntyre, who are still employed by the Railway Company. **If the Peckham Company can get a letter of a similar purport or anything nearly approaching it from the predecessor of Mr. Shelmerdine who was in office and cognizant of all the facts at that time, we will be glad to give a thousand dollars to any worthy object named by Mr. Peckham.** The facts are that an order was given by the People's Company to ourselves and the Peckham Company for 125 trucks each. The model submitted by Peckham was the one on which his first few trucks were made, and this would not hold up the ends of the open car bodies, and a different truck was substituted at a higher price. The second type of Peckham truck was also found incapable of doing this work, and two changes in the trusses were found necessary before they were accepted; nor do they now properly support the open car ends, as is patent to any observer. The Brill trucks worked steadily and admirably, and were duly accepted and paid for in full by the railway company, and they continued to do the work until the consulting engineer of the Peckham Company, McIntyre, had worked the matter so as to have the Brill trucks discarded by the People's Traction Company. The subsequent career of McIntyre affords a shrewd indication of the probability of the honesty of this arrangement. The Peckham Company has been unfortunate in not having a consulting engineer in the service of other roads, notably the Pittsburgh Traction Company.
>
> We can moreover state this fact, that 21 of the Brill trucks which were condemned by the late general manager, McIntyre, were bought by the Pennsylvania Railroad Company for their Atlantic City road, where they have been in successful operation during all of the past summer on that company's most admirable electric railway. Yours very truly,
>
> J. G. BRILL CO.

The statements made by ELECTRICITY in regard to this truck question were correct.

Plenty of similar examples of McIntyre's conduct might have been cited; for instance, his discarding Lewis & Fowler registers, and replacing them with Meaker registers within six months after taking control at Philadelphia. At that time the Lewis & Fowler register was standard; three times as many of them were in use as of any other type. The Meaker register at that time certainly had no points of superiority. The reason for the change was the usual McIntyre reason.

And now we have a few words to address to Mr. Peckham:

Is the charge that trucks made by your company happened, in one instance, to be improperly made, more damaging to your reputation than the charges as to your relations with Mr. McIntyre? Is it less honorable for you to bear the responsibility of mistakes made by your mechanics than to rest under the charge that while L. H. McIntyre was a salaried employee of the People's Traction Co., vested with the authority of purchasing all apparatus, he, as "consulting engineer," received large sums of money from your company contemporaneous with this purchase of trucks from your company?

You have attempted, Mr. Peckham, to dodge the main question at issue.

The subject of our article was, "What's in it for me?" The meaning of this question was thoroughly elucidated. The questions involved in the truck matter were minor ones.

Being an honest man, familiar with the English language, also familiar with McIntyre, his methods, and the methods of others of the same class, you are specially fitted to write an answer to our arguments on this subject.

Any reasonable amount of space, say two pages, is at your disposal for a letter of this kind, and there will be no charge.

Directors of the railway companies of the country know that you generally make very fair trucks. But they don't know whether your company is a safe one to deal with until you have explained in full your relations with L. H. McIntyre.

* * *

Canal Traction and Newspaper Duty.

Something over four pages of the *Electrical Engineer*, and one page of the *Electrical World*, were given up last week to an illustrated description of an experiment in electric traction on the Erie Canal. The "system" consists of an electric motor and carriage suspended from a cable on the heel path of the canal, drawing one or more canal boats.

The comments of our contemporaries on this matter show that notwithstanding all their loss of prestige from indiscriminate puffery of enterprises of a like character during the past fifteen years, the lessons of experience have been wasted upon them, and they are still ready to lend their names to any scheme brought forward which promises them financial return, or which helps to fill space with pretty pictures. No matter how unstable or culpable the scheme; these journals can always be relied on to help it along and co-operate in the deception of the public.

The only common sense views expressed on this canal towage enterprise in the electrical press, outside of our own columns, have been found in the *Western Electrician*, as follows:

> There has been no data presented showing the efficiency of the electrical apparatus, nor is there any other means at hand of making a comparison with the older methods which it is hoped to supplant. Of course the economy and efficiency of the proposed system will have much to do with its general adoption, and until further particulars on these points are to be had there is no use considering the scheme as a practical measure.

No data on the question of cost of this power to the company proposing to supply it have been given out. None of the representatives of the technical press present appeared to have any interest in making tests to see how much power was required. It was enough for them to see the wheels turn round. The wheels turned, *ergo* the entire scheme is already a success. The *Electrical Engineer* said editorially:

> Hearty congratulations are to be extended Messrs. Lamb and Hawley, as inventor and promoter respectively of the ingenious method *adopted successfully* last week for operating the Erie Canal by electricity. It will be remembered that Mr. Hawley made a previous trial with the ordinary trolley system; but the ideal plan of hauling from the bank has been adopted and we believe great results for good will ensue. The inexhaustible energy of Niagara will not only be applied to the canal, and following its lines penetrate into the interior of the State, but other canals now grassgrown or green with the slime of years will be reclaimed. We may see even a period of canal "grayhounds" furnishing cheap and very comfortable transportation for passengers; but the freight part of the question will of course be first dealt with.

Mr. Lamb invented (?) his system for application in a logging camp where a solid roadway was next to impossible—a very proper reason for putting the motor in the air; and the only proper reason.

Along the Erie Canal from Buffalo to Albany there is one of the finest roadways in the world—already prepared fit for a steam or electric railway at the cost of millions to the State. Is not this the proper place for whatever kind of traction engine is used? The *inevitable* sag of the cable is enough of itself to double the power required to move a canal boat.

Some days before the latest test was made Mr. Frank W. Hawley called upon us to invite us to be present on the occasion. Incidentally he complained that we had pronounced against his scheme and himself, and had thereby seriously injured him. We told him that his personality had not been a factor with us at all, but that *we regarded* the plans as published entirely unfeasible and sure to end in failure. We regarded the whole scheme as an attempt to gull the public for stockjobbing purposes, and told him that while no attempt to discredit the electrical industry could find space *in* our columns except in the way of exposure, any legitimate scheme that would benefit the industry could have all the space that was desired, and without cost. We did not, however, believe that Mr. Hawley's scheme belonged to the latter class.

He protested so strongly and argued so well for the honesty of his purpose that we were half inclined to believe that we had misjudged the man if not the scheme, and had decided to withhold further judgment pending developments. On October 21 a preliminary trial was made of Mr. Hawley's scheme, and, although it proved a failure in this instance it is not the failure that we wish to advert to at this time, but Mr. Hawley himself.

One of the New York daily papers on the following day published the following :

> Mr. Hawley says that if the plan is approved by the State he is prepared to furnish electric motive power for 3,000 canal boats now moved by horses. Regarding the transmission of electric power over long distances, Mr. Hawley said that it was as easy to propel a car up the Capitol Hill at Albany with power generated at Niagara Falls as it was to operate an incandescent lamp at Goat Island in the Niagara River.
>
> "Ships in New York harbor will be loaded and unloaded before long with derricks operated by electricity generated at Niagara Falls," he said.
>
> It is claimed for this system that it will give any speed desirable, and will not injure the banks of the canal. The power will be furnished to canal boat owners at $20 per horse power per year. The locks and bridges can be operated by electricity, and the canal can be illuminated at night from the same wires that carry the power.

These claims are so absurd that if Mr. Hawley is really guilty of having made them he has thereby enrolled his name among the list of charlatans which includes the names of the manufacturers of the Electric Belt, the Electropoise, the Earth Magneto and Dr. Beckwith's Thermo-Ozone Battery.

We do not care whether Mr. Hawley's scheme has merit or not (we are sure that it has not), it must receive the condemnation of every honest man simply because charlatan methods, as above quoted, are employed to bring it before the public.

The triumphs of electricity require no fiction to make them appear remarkable. When we see a man gilding refined gold or painting the lily, we are very apt to conclude either that the man is a fool or that the gold or lily is bogus.

We do not think Mr. Hawley is a fool.

Four days after the second trial of this "ingenious method successfully adopted" there was a mass meeting at Cooper Union attended by over 3,000 people in the interest of the proposed appropriation of $9,000,000 for improving the efficiency of our canal system. If the economy and consequent desirability of hanging a motor carriage in the air have been so clearly proved, why was it that none of the dozen or so speakers—the men of all others best posted on the needs of the canals—did not present an argument for the "system."

An electric railway on the towpath for towing canal boats would no doubt be a long step in advance of present methods. A steam road for the purpose would long since have been built there had it not been for the successful opposition of railway interests.

But after a close study of the canal problem, extending over several years, we have no hesitation in declaring it as a proven fact that what the canals need is *more water*, a wider and deeper channel. Until this is provided the problem will not be solved either by electricity or any other method of applying power.

When the water has been provided, electric towing engines, supplied with power at intervals of twelve or fifteen miles, will do the rest.

* * *

THE circumstances of Franklin L. Pope's death recall the testimony given by him at the time efforts were being made to set aside the electrocution law in New York State. In July, 1889, counsel for William Kemmler, applied for a writ of habeas corpus on the ground that the State Constitution forbids the execution of a criminal by cruel and unusual means. Tracey C. Becker, of Buffalo, was the referee before whom testimony was taken. Among the many experts examined none gave more complete or more impartial testimony than Mr. Pope.

Bourke Cockran began the direct examination of Mr. Pope with a series of questions to show that there did not then exist, and probably there wouldn't be devised, any means of measuring accurately the resistance of the human body, and that the death of a man by electricity depends upon several contributing causes. Mr. Pope stated, as the result of experiments made by himself, that the resistance of his own body, as measured by a Wheatstone bridge, varied from 6,300 ohms with a current of one volt E. M. F. to 3,500 ohms with a current of 100 volts. This variation, he said, "is due to the chemical actions upon the fluids of the body." Answering the question, "Can electrical science measure the resistance of a living organism?" he said : "Well, you would get a result each time, but you can't tell whether it would be accurate."

Other questions propounded and their answers were:

Q. Do you know whether death by electricity is painful or not?

A. I believe it is very painful.

Q. Is it recorded anywhere in science what voltage would be required to kill a human being ?

A. No. Wires for lighting are always charged to a certain extent. Sometimes the current, when a person comes in contact with it, kills and sometimes it does not.

Q. Then there are contributing causes?

A. Yes, sir.

Q. Could you, as an expert, describe a current which in every case and with every person would absolutely cause death?

A. No, I could not.

Under the Searchlight.

Views and Opinions on Timely Topics.

IF the General Electric Company have, as reported, paid $500,000, or any other considerable sum, for the Love conduit patents, they certainly have more money than brains. What New York City is waiting for is a successful conduit system not costing a prohibitive price for construction. What the trade wants and needs, and must have if it is ever to be upon a basis of profit earning, is the eradication of what may be termed the patent disease. The large electrical companies, after wasting millions upon millions in ready-made patents and patent litigation, are still spending the money of their stockholders for worthless patents and using their patent claims for stock-jobbing purposes to the neglect of their natural business—the manufacture and sale of apparatus. And we cannot express our sense of regret when it became apparent that another electric company, from whom was expected nothing but conservatism and aid in purifying the trade, had become a victim of the same disease which has been the main cause of the unsatisfactory conditions existing in the electrical trade of America to-day. We advise every company in this business to let trades, deals and patent manipulations severely alone and saw wood.

Mr. Westinghouse's Views.

Mr. Westinghouse is reported as follows in conversation with President Roberts and other officials of the Pennsylvania Railroad :

> The Pennsylvania Railroad to-day, it is said, consumes about 5,000,000 tons of coal per annum on its lines east of Pittsburg, taking approximately 20 loaded trains each day for its transportation and consequently the return of 20 empty trains, and requiring for the service of the company alone fully 3,000 cars and a proportionate number of locomotives.
>
> If this power was to be generated by gas locomotives only about one-eighth, or 600,000 tons of coal per year would be required, effecting a saving of over 4,000,000 tons of coal, now costing the railway about $5,000,000, a saving which would justify a large enough capital expenditure to cover the complete equipment of the railway.
>
> To carry out an arrangement of the trains Mr. Westinghouse said that stations having electric generating plants, with gas engines and producers, could be located at intervals of from ten to twelve miles so that there would always be two or three stations furnishing current for any particular part of the line.

We desire to call the attention of all transmission cranks and visionaries to the intervals between stations suggested above.

EXCITEMENT IN A QUIET TOWN.

(From the Philadelphia Inquirer, Oct. 31.)

> The Philadelphia stock market had the liveliest shake-up yesterday it has experienced since the Reading Railroad collapsed, nearly three years ago. The "Philadelphia Kaffirs," as they have been called, went all to pieces, one stock breaking $17 a share in two hours' time.
>
> Symptoms of weakness in this group appeared on Monday night, when the United Gas Improvement directors suggested a stock dividend of only 15 per cent., instead of 20, as had been considered probable. The next day United Gas, Welsbach Light, Electric Storage and Pennsylvania Light, Heat and Power, which constituted this group of stocks, were all lower. Electric Storage, which sold at 73½ on Monday morning and 70 on Monday night, broke to 65 on Tuesday, but the speculative community all imagined the directors would support the stock and hence were not particularly alarmed. Yesterday morning, when the stock sold up to 66¼, they felt quite easy. They imagined the insiders were ready with supporting orders and would prevent a serious decline.
>
> But the bank officials of the city were not as well satisfied on this point. Some of them had made loans to stock brokers, taking as collateral in part Electric Storage stock. They did not like the decline in the price, and yesterday morning suggested to some of the brokers that the loans be reduced in size or additional collateral be put up. That was enough. The brokers at once attempted to sell the stock out and found the insiders were not there with supporting orders. Then the market went all to pieces.
>
> A few shares were sold from 65 down to 60 and then there was a brief wait for the inside support to come out. It did not come. The stock dropped at once from 60 to 58. Still no support. Then came a break to 55 and then a downward plunge to 48. Between 60 and 48 only 2,500 shares were sold. But at that price outside buyers came in and put the stock up to 55. This was taken at first for inside support, but it was a mistake. There was no such thing, and the stock broke again to 47. In the last hour, however, it rallied. While this was going on the preferred stock, Welsbach Light, United Gas, and Penn Light, Heat and Power were all going through the same experience.
>
> The Street simply boiled with excitement. Clerks were running about with notes to people who had the stock to put up more margin. Many were unable to respond and their brokers at once sold them out. In every office crowds gathered about the ticker and every decline was shouted out. On the floor of the Exchange the scene resembled a fight in a madhouse. Brokers were howling and jumping about in a crazy manner. All were glad when the close came. But there were many white faces in the crowds of people that surged out of the brokers' offices when the clock struck 3.

* * *

What President Gibbs Says.

W. W. Gibbs, president of the Electric Storage Battery Company, says that "the decline in the securities of the company is unwarranted. The business of the company is growing rapidly, current receipts are constantly increasing and numerous extremely important installations are in process of consummation. No business is upon a more substantial basis to-day than the storage battery business. While litigation has delayed the exploitation of that industry in this country until six months ago, when we obtained control of all the patents, the enormous business and large profits secured by the storage battery companies in Germany, France and England give an earnest of what is awaiting us here. We have installed a large number of extremely important plants; our factory is working full time and a very large extension to it is now in progress."

* * *

THE list of electrical newspaper men who have shown their wisdom and stability during the last year or two includes Messrs. Kreidler, Keily, F. L. Perry, Nelson W. Perry, Wetzler and Montgomery. The only hesitant remaining, so far as we know, is Mr. W. D. Weaver of the *Electrical World*. We trust

Mr. Weaver may soon be brought to a realizing sense of his unfortunate position and find a wife. Perhaps not the only, but certainly the biggest, cranks in the world are old bachelors and old maids—and the latter are not to be blamed because they would not be so if every man did his duty. The community now waits for Mr. William Delinquent Weaver.

* * *

The Barnes Boys.

(From the Buffalo Express.)

Several newspapers have been mixing the Barnes boys up. The Thurlow Weed Barnes who has bolted the nomination of Frank D. Pavey for the Senate is not the owner of the Albany *Journal*, but that young gentleman's elder brother, and like him, a member of the Republican State Committee. While William Barnes, Jr., lives in and nominally bosses Albany, Thurlow Weed Barnes represents one of the New York districts. William Barnes has been longer in politics, and is therefore better known than his big brother.

For the information of those who have not seen both, it may be said that Thurlow looks like Willie, but is twice as large and built like a prize-fighter. Thurlow is on Easy street, financially, by dint of a judicious marriage with a daughter of John A. Morris, the lottery king. He used to be a member of a publishing house in Boston, but has returned to New York and engaged in politics. Heretofore he has been chiefly known to fame on account of a cable despatch he is said to have sent to the Prince of Wales announcing the death of Thurlow Weed. This historic message read simply: "Grandpa is dead."

The peculiar reputation of the Barnes brothers rests on the fact that they say things that older politicians only allow themselves to think.

* * *

Is Mr. Morgan Tired?

(From the Boston News-Bureau.)

Brokers who have been watching the selling of the market very closely this week say there have been unmistakable signs of large selling orders coming from Morgan interests, and that the break in Reading and General Electric can be traced rather directly to this source.

* * *

MR. W. J. HAMMER is now making a trip through the West as a plain everyday arc lamp salesman. We suppose he will, of course, call on Mr. Andrew Hickenlooper when in Cincinnati.

* * *

The Way It is Done in Chicago.

[COPY.]

Chicago, Ill., October 24, 1895.

Sealed proposals will be received until November 2, 1895, for furnishing the city of Chicago with 19,648 feet, more or less of Day's Kerite, single conductor, electric light cables, as per specifications on file in the office of the Superintendent of City Telegraph. Proposals must be made out on blanks furnished by the latter official and addressed to Comptroller, City Hall, Chicago, Ill., and endorsed "proposals for Day's Electric Light Cables." Each proposal must be accompanied by check for $200.

O. D. WETHERELL, Comptroller.

Echoes from the West.

(From the St. Louis Chronicle.)

SWINDLED.

ST. LOUIS CAPITALISTS SAID TO HAVE BEEN VICTIMIZED.

It is rumored that ex-Judge George A. Madill, Wm. H. Thompson and a dozen more prominent capitalists have been victimized by the Standard Telephone Company.

John W. Candler, a Boston banker, came here several months ago to organize the company and got fifteen men to put in $1,000 each. ELECTRICITY, a New York class paper of high standing, says the whole thing is a bare-faced swindle.

* * *

HERBERT E. RIDER, inventor of the Earth-Magneto fake, is a prolific genius. Not content with having discovered a method that will permanently cure all forms of nervous diseases, gout, dyspepsia, constipation, rheumatism, neuralgia, sciatica, insomnia or sleeplessness, melancholia, paralysis, lumbago, pain in the back or limbs, and kidney, bladder or liver complaints, headaches, nervousness, female complaints, wasting diseases, he is tackling problems of greater magnitude.

The most recent product of his gigantic brain is a plan for running mighty dynamos by power that can be taken from the rise and fall of the ocean's tide and the turbulence of its waves. He says that some noted engineers are considering his plan, and they pronounce it highly practicable. Instead of utilizing the back-and-forth motion of the tide and waves, he gets his power from the vertical motion.

"I can get enough power from the waves along Coney Island to heat and light the whole of New York City," is the inventor's modest estimate of the possibilities of his latest discovery.

THE CORBETT-FITZ FIGHT A GO.

(Special despatch to ELECTRICITY.)

HOT SPRINGS, Ark., Nov. 5.—The Corbett-Fitzsimmons contest is to be pulled off after all. New articles of agreement were drawn up and signed today, by the terms of which the contestants agree to do battle in the most approved style of modern pugilism. Two phonographs are to be placed in the diagonally opposite corners of a 24-foot ring. Into the receivers of these instruments the principals are to talk for six consecutive hours, the battle to be awarded to the contestant who shall speak the greatest number of words within the time limit.

The phonograph people have sent telegraphic orders for a car load of cylinders.

The betting is active, with odds about even.

The Standard Telephone Co.

Questionable Methods and Conduct.

On October 16, there was printed in ELECTRICITY a photographic fac-simile of a circular prepared and issued by the Standard Telephone Company, of New York. Gen. James S. Clarkson made a somewhat equivocal denial of the authenticity of this circular, but no other denial from any of the heads of the concern has so far appeared. No answers have been received to the following letters mailed to Messrs. Clarkson and Barnes nearly two weeks ago:

[COPY].

"ELECTRICITY,"
6 Park Place, New York.
October 25, 1895.

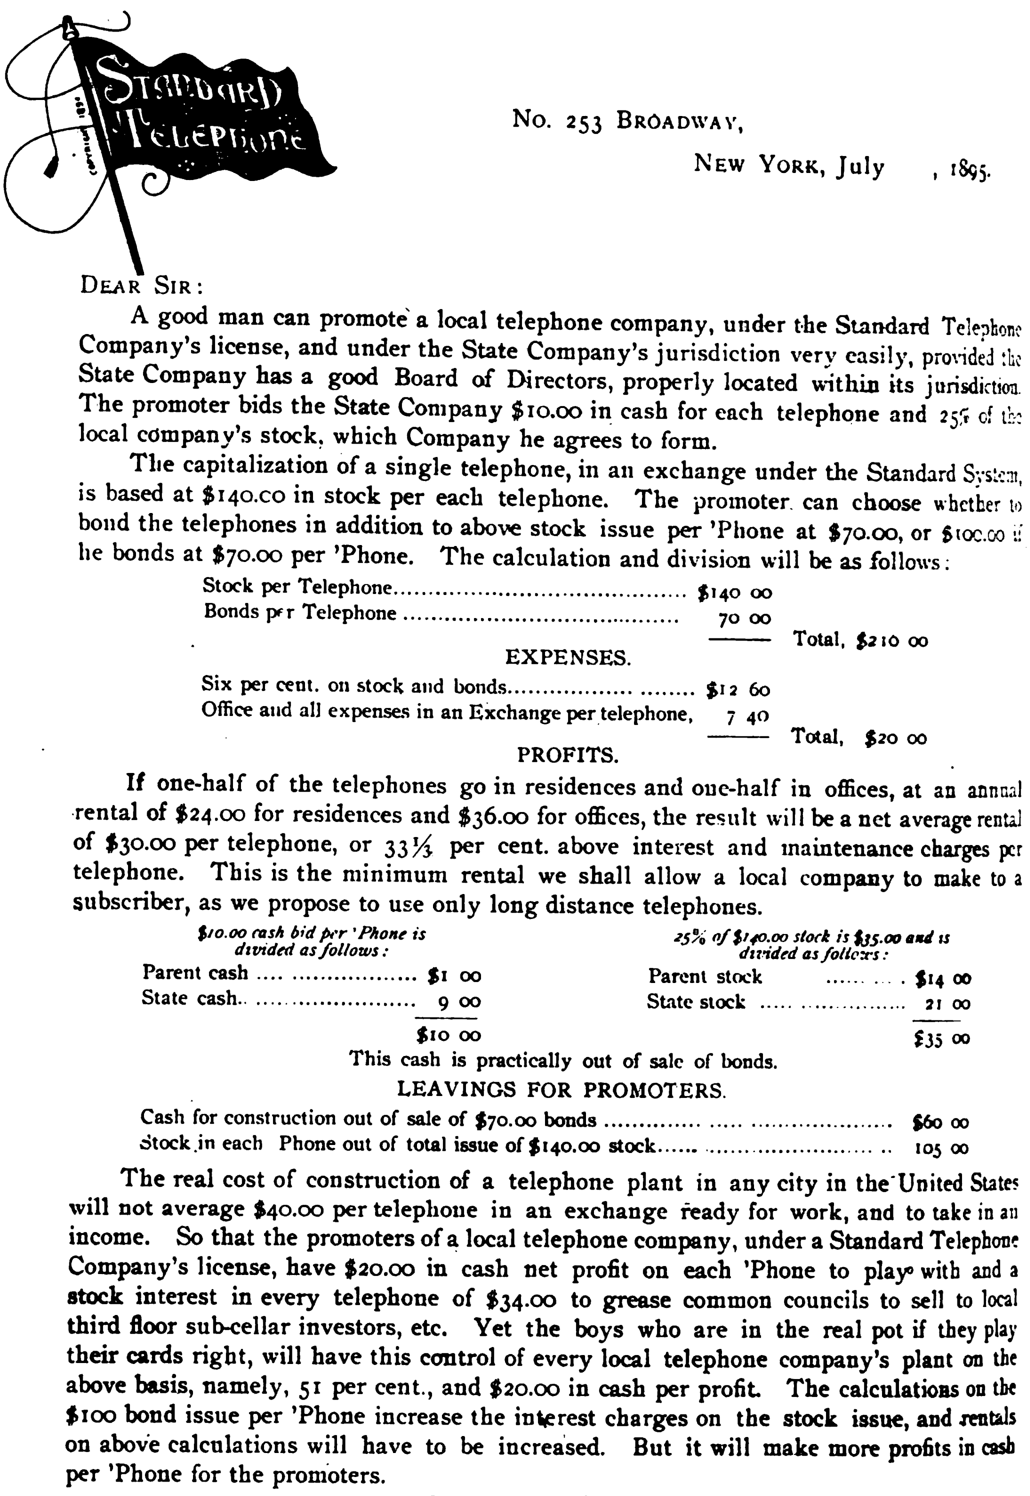
HON. J. S. CLARKSON,
Fifth Ave. Hotel, New York.

DEAR SIR: I notice in a recent interview attributed to you, in the *New York Herald*, a denial of the authenticity of a Standard Telephone circular recently published in this paper, and would esteem it a favor if you will make such denial over your own signature, and forward to me.

Yours very truly,

(Signed) B. E. GREENE, Publisher.

(Dictated.)



STANDARD TELEPHONE

No. 253 BROADWAY,
NEW YORK, July , 1895.

DEAR SIR:

A good man can promote a local telephone company, under the Standard Telephone Company's license, and under the State Company's jurisdiction very easily, provided the State Company has a good Board of Directors, properly located within its jurisdiction. The promoter bids the State Company $10.00 in cash for each telephone and 25% of the local company's stock, which Company he agrees to form.

The capitalization of a single telephone, in an exchange under the Standard System, is based at $140.00 in stock per each telephone. The promoter can choose whether to bond the telephones in addition to above stock issue per 'Phone at $70.00, or $100.00 if he bonds at $70.00 per 'Phone. The calculation and division will be as follows:

Stock per Telephone	$140 00	
Bonds per Telephone	70 00	
		Total, $210 00

EXPENSES.

Six per cent. on stock and bonds	$12 60	
Office and all expenses in an Exchange per telephone,	7 40	
		Total, $20 00

PROFITS.

If one-half of the telephones go in residences and one-half in offices, at an annual rental of $24.00 for residences and $36.00 for offices, the result will be a net average rental of $30.00 per telephone, or 33⅓ per cent. above interest and maintenance charges per telephone. This is the minimum rental we shall allow a local company to make to a subscriber, as we propose to use only long distance telephones.

$10.00 cash bid per 'Phone is divided as follows:

Parent cash	$1 00
State cash	9 00
	$10 00

25% of $140.00 stock is $35.00 and is divided as follows:

Parent stock	$14 00
State stock	21 00
	$35 00

This cash is practically out of sale of bonds.

LEAVINGS FOR PROMOTERS.

Cash for construction out of sale of $70.00 bonds	$60 00
Stock in each Phone out of total issue of $140.00 stock	105 00

The real cost of construction of a telephone plant in any city in the United States will not average $40.00 per telephone in an exchange ready for work, and to take in an income. So that the promoters of a local telephone company, under a Standard Telephone Company's license, have $20.00 in cash net profit on each 'Phone to play with and a stock interest in every telephone of $34.00 to grease common councils to sell to local third floor sub-cellar investors, etc. Yet the boys who are in the real pot if they play their cards right, will have this control of every local telephone company's plant on the above basis, namely, 51 per cent., and $20.00 in cash per profit. The calculations on the $100 bond issue per 'Phone increase the interest charges on the stock issue, and rentals on above calculations will have to be increased. But it will make more profits in cash per 'Phone for the promoters.

Yours very truly,

[COPY].

"ELECTRICITY,"
6 Park Place, New York. October 25, 1895.
THURLOW WEED BARNES, ESQ.,
President Standard Telephone Co., New York.

DEAR SIR: I notice that in interviews with various people connected with your company, the authenticity of one of your telephone circulars, recently published in this paper, is denied, and I beg to advise you that you are at liberty to use whatever space in our columns is necessary to deny that the circular in question was prepared and issued by the Standard Telephone Company of New York.

Yours very truly,
(Dictated.) (Signed) B. E. GREENE, Publisher.

We have deemed the matter of sufficient importance to the telephone public to reproduce the circular again this week. It appears on the preceding page.

It was prepared in and issued from the New York office of the Standard Telephone Company early in July.

On July 27 an original copy of it, properly dated and signed by an officer of the company, was sent to the *New York Herald* by a gentleman who had received it in his mail. It was sent for publication as news matter, and just why the *Herald* did not use it we do not know. It is scarcely possible that they would suppress it for pay.

We print below another circular issued by this remarkable concern. It contains no reference to greasing common councils, yet it is as clear proof of the flimsy character of the Standard Telephone Company's plan as could be desired. The claims made are ridiculous and could not be made by any man familiar with the telephone business unless he planned a stockjobbing scheme to secure the money of men wholly ignorant of telephone possibilities:

(CONFIDENTIAL.)

OFFICE STANDARD TELEPHONE COMPANY,
253 Broadway, New York,
Postal Telegraph Building.
ALLEN T. NYE, General Manager.

PROSPECTUS of Parent and State Standard Telephone Companies as to the capitalization of a single telephone in an exchange, complete and ready for work:

(1) That a uniform capitalization of $140 per telephone shall be compulsory throughout our systems, with the privilege to promoters of local companies to issue bonds on each plant to the amount of $70 per telephone, which, by the written consent of the Parent and State Telephone Companies, may, under certain conditions, be increased to $100 per 'phone for constructing the necessary plant and exchange system.

(2) The bonds issued by each local company must be retired and cancelled within twenty years from the surplus earnings of the plant and cancelled within less time if it be possible to place the bonds for a less period at an equally advantageous rate of interest.

(3) The promoter of local companies must accompany his written proposal for the concession of territory with an agreement to pay $10 in cash per telephone, and to deliver twenty-five per cent. of the $140 in stock issued against each telephone in his district to the Parent and State Companies. The cash and stock thus paid being divided as follows:

$1 to the Parent Co.,	$14 in stock to Parent Co.,
9 to the State Co.,	21 in stock to State Co.,

Total, $10 in cash per 'phone. To., $35 in stock for license.

(4) Promoters of local companies will be required to give the general managers of the Parent and State Companies satisfactory proof that they possess the necessary financial ability, and are men of sufficient responsibility and character to secure charters and subscribers in the territory in which they desire to establish exchanges, as well as credit and rating for any bonds that may be placed on the market by them for constructing their proposed plants.

(5) The money realized from the sale of the seventy dollars in bonds issued against each telephone is to be used in the construction of the local telephone system, the detailed disbursement of the money thus secured being estimated as follows:

Purchase of telephone	$20
Construction of lines, allowing one mile of No. 12 copper wire per 'phone	20
Construction and installation of exchange per 'phone	20
License—cash bid as above	10
Total	$70

The cost of construction here set forth is very liberally estimated for any city in the United States, while in many it will be far less.

On the completion of the local telephone system, the fixed charges per 'phone and annual cost of maintenance will be as follows:

Interest on bonded indebtedness of $70 per 'phone at 6 per cent. per annum	$4.20
Cost of maintenance and operating per annum per 'phone	16.60
Total for operating and fixed charges per annum.	$20.80

Taking the average annual rental of each telephone at $30, which is the lowest rental that the Parent and State Companies will consent to for a long distance telephone, and the cost of the operating and fixed charges as above, the following comparison is presented:

Gross annual income per telephone	$30.00
Fixed charges and operating expenses per annum	20.80
Net income per 'phone per annum	$9.20

The real profits realized by the promotion company building the local system will be, at least $20 in cash out of the estimated construction cost of $60 per telephone, less license fee; and, after the bonds of $70 per telephone have been cancelled by the surplus earnings of the plant, the promotion company will absolutely own seventy-five per cent of the local company's stock, or $105 of stock of each telephone in its district, with all the immense earning capacity of the plant at above low rentals, and this promotion company in the construction of its plant will deal directly with the electrical construction companies on a business basis—lowest bidder first class work securing the contract.

On the completion and installation of each exchange, for each one hundred telephones thereafter installed and in operation, the local company will be required to make an additional issue of $140 in stocks and $70 in bonds against each telephone, twenty-five per cent. of which stock and $10 cash per 'phone is to be paid to the Parent and State Companies, and the remaining seventy-five per cent. of stock, with the money realized from the sale of the bonds, to be used by or held in the treasury of the local company as an additional construction and improvement fund, or subject to same conditions as an original organizatson of the plant.

PROPOSAL NO. 2.

When a bond issue of $100 per telephone is permitted, the minimum rental per long distance telephone will be $36 per annum, the conditions governing the issuance of the bonds being the same as where the issue of bonds is $70 per telephone.

In exchanges established under an issue of $100 in bonds per telephone, the annual fixed charges, cost of maintenance and operating will be as follows:

Interest on $100 in bonds at 6 per cent. per annum	$6.00
Cost of maintenance and operation	16.60
Total	$22.60

On this basis the net income of such exchanges will be as follows:

Gross annual income per telephone	$36.00
Fixed charges and operating expenses per annum	22.60
Net income per 'phone per annum	$13.40

The issue of bonds to the extent of $100 per telephone will be sanctioned only where extraordinary circumstances may warrant it, and only on the written authorization of the Parent and State Companies.

The same conditions covering the concession of territory and the issuing of license to local companies will be pursued in the establishment of both classes of exchanges, as well as in the provisions regulating the increased issue of stock and bonds to provide for the extension and enlarging of exchanges by the installation of additional telephones.

It will not cost $16.60 to operate a telephone in any exchange in America outside of New York and Brooklyn, and $16.60 is away above the cost in New York and Brooklyn, and on the above low costs of rental per 'phone there is 6 per cent. interest on the stock and bonds issued against a telephone and a surplus to retire the bonds when they mature.

Respectfully,
ALLEN T. NYE, General Manager.

There has been nothing in the career of this company to inspire confidence—except the names of eminent men connected with it. Names, however, are an insufficient basis to warrant any company in selling State rights for something which they cannot deliver, and unless all signs fail the courts will soon be called upon to decide whether or not those who have paid in $1,000 apiece in the organization of State companies have lost their money legally or otherwise. That it is lost there is little doubt.

In connection with this circular to the "Boys who are in the Pot," it is proper to reproduce the names of the officers and directors of the parent Standard Telephone Company. As given in a recent reading notice in the New York *World*, they are as follows:

THURLOW WEED BARNES, president.
MANNING C. PALMER, Syracuse, treasurer.
ALLEN T. NYE, New York, general manager.

DIRECTORS.

CARL F. BOKER, New York.
JOHN A. BRILL, Philadelphia.
HON. WILLIAM J. CAMPBELL, Chicago.
HON. JOHN W. CANDLER, Boston.
GEN. JAMES S. CLARKSON, Iowa.
GEORGE CROCKER, California.
A. L. CONGER, Ohio.
ALBERT M. DAY, Chicago.
SENATOR JOHN P. JONES, Nevada.
HENRY MERZ, New York.
FELIX RACKEMANN, Boston.
HON. JOHN S. RUNNELLS, Chicago.
COL. JACOB RUPPERT, New York.
CLARLES T. STRAUSS, New York.
LOUIS WINDMULLER, New York.

How would these gentlemen like to write their autographic signatures under the proposition of which we print a photographic fac-simile? None has done so, so far as we know, except one. Yet, is their position much better than it would be had each and everyone of them signed it? Corrupt promoters throughout the country are still trying to raise money for Standard Telephone rights, and the names printed above are their chief stock in trade. It is not the name of Allen T. Nye which has secured subscriptions of over $300,000 for these rights. It is the names of those whom he was shrewd enough to get into his scheme. And until every one of them denounces in positive language the methods so far followed by the Standard Company, and disclaims any knowledge of what has been going on on the inside, they can justly be held responsible for the conduct of the company's affairs. Indeed, if they are to save their reputations they must go further, and renounce all future connection with the enterprise or give personal guarantees that the representations made by the official promoters of the scheme will be made good. No other course is left open to them, and explanations are in order.

When the plans of the Standard Telephone Company were first made public, there was a capitalization of no less than $260,000,000 for the parent and district companies. Why was it that none of the honorable gentlemen who lent their names stopped to consider the inconsistency of this part of the plan? If this amount represented actual money, then no *new* company was needed. With $260,000,000 the entire capital stock and bonds of the Western Union Telegraph Company, the Postal Telegraph Company, and the Bell Telephone Company could have been purchased, and the most comprehensive and profitable monopoly the world has ever seen established at once.

But of course no such amount of money was ever dreamed of. There has been nothing but paper exposed to view, except the $300,000 or so of outsiders' money paid in in the organization of the district companies. And paper entered largely into this arrangement. In fact, the whole enterprise has been so exclusively on paper that we fail to see how the gentlemen who paid in $1,000 apiece for State or district rights can come in for much public sympathy in the loss of their money. The proposition laid before them by the original promoters lacked all the elements of sound business.

For the $1,000 paid in for an interest in the district companies, each one received from $25,000 to $50,000 of stock in the parent company. Does any business man know of a case where stock distributed in such a prodigal manner has ever had any real value? We do not.

In the *World* reading notice referred to the following appeared:

> An announcement of some of the purposes of the company, coupled with an alleged list of prominent gentlemen interested in it, that appeared in Chicago about six months ago, was not only unauthorized but was published against the wishes of the managers. While some of the statements that were then made

were substantially correct at the time, they were still very much exaggerated. . . . An investigation traced the disclosure to the person who gave out the information, and he was dismissed from the local branch. The information was sold to a stock-jobbing firm and was undoubtedly furnished for an illegitimate purpose. Attacks on the Standard Telephone Company which have appeared are said by its managers to have an equally illegitimate object.

We do not wonder that it was the intention to conduct this campaign with as much privacy as possible. It must have been well known to the original promoters that it would not stand publicity and dissection in the press of the country.

Officers of the Standard Company have lately charged that the exposures made in ELECTRICITY of its plans and methods are directly in the interest of the Bell Company. They are; but through no choice of ours. ELECTRICITY'S opinions of the Bell Telephone Company are on record, as are also our continued labors in behalf of a solid and legitimate independent telephone movement. No explanation of our course is necessary. It speaks for itself.

But every exhibition of rascality in independent telephone circles is welcomed in the Bell camp with as much joy as a patent decision in their favor. Nothing could have given them greater delight than our exposure of the Standard Company's methods. A few more episodes of a similar nature, and no telephone scheme, no matter how much merit it possesses, can command any capital whatever. This the Bell Company knows. Hence their satisfaction. ELECTRICITY is therefore compelled by a sense of duty to work temporarily in the interest of a company which it never endorsed, and whose methods it never approved of. But this work is only temporary.

The Standard Telephone Company will soon be disposed of, or the best opinion in the telephone world is all wrong. When this is done others will hesitate a long time, we think, before undertaking a similar project.

A scandal raised by any one company cannot kill so strong a movement as the independent telephone movement of 1895. And when the paper companies, the speculators and adventurers have all been driven out, the air will be clearer, capital will feel more confidence, and the legitimate companies in the field will go forward to solid successes.

As to the past record of the Standard Telephone Company it is a matter of history. There has been nothing but continued deceit and misrepresentation.

Long distance lines were promised first. Local capitalists were promised this as an inducement to go ahead and organize local exchanges. The method of organizing district companies has been explained. When it came to local exchanges the plan was practically the same—the promoters were again to receive the larger part of the money, and the exchange was actually to be built from the proceeds of the sale of bonds. Bonds on what? Prospective property, franchises and subscriptions for the service of the exchange secured in advance! Bonds of this nature are not easily disposed of, and as a consequence no local exchanges have been started.

The $1,000 men from various States who have expressed anxiety as to what they are getting for their money are told to wait. Wait for what? The best posted men in this city are unable to answer the question. Standard officials decline to explain what they mean. They look wise and say again, "Wait and see what we are going to give you."

The facts as we believe them to be are that the company has nothing to wait for except dissolution. There has been nothing of late to change our opinion. The reading notice in the *World* contained nothing but buncombe and false statements. Of the latter the following is a sample:

"About this Berliner question, the plain truth is that this patent was unjustly obtained by Emile Berliner for that which was in fact the invention of James W. McDonough, of Chicago, who was using reasonable diligence in adopting and perfecting the same; and all the McDonough patents are now owned and for some time have been under the control of the Standard Telephone Company, the president of the Standard being also president of the McDonough, and the other McDonough directors are either directors in the Standard or are clerks in the employment of the Standard Company. For this and for other reasons the Standard does not worry itself about the Berliner litigation."

The Standard Telephone Company does not own the McDonough patents.

A bill of sale of these patents is now and has been in the possession of another telephone company in this city.

Other patents claimed are those of A. W. Rose. Mr. Rose is a patient and industrious worker in the employ of the Standard Company. His patents are not mysterious at all. Copies of them all are now in our office. There is nothing in them to warrant the formation of any company to exploit them in competition with what is already in *practical use* in the field of telephony.

The only telephone man of any ability ever connected with the enterprise was H. H. Eldred, who long since ceased to work in harmony with the company.

Official claims as to the switchboard were printed by us last week. They are too silly to be worthy of comment, and are to be placed on a par with Mr. Allen T. Nye's claim, a few weeks ago, that he could put a diamond drill at work at the foot of Broad street and have a telephone subway fit to lay wires in to the Sub-Treasury building, at Broad and Wall streets, in twenty-four hours.

Over $300,000 of money has been paid into the Standard Telephone Company's treasury by presumably honest investors who supposed they would get something for their money. The money is nearly all now in possession of the company or of the four men who composed the original syndicate, Thurlow Weed Barnes, Allen T. Nye, Charles T. Strauss and J. O'Neill. Not one promise made by the promoters has been kept. Little wonder that a procession of the humbugged has besieged the offices of the company in the Postal Building since ELECTRICITY'S exposure was published.

We print, as of passing interest, some of the comments of investors in the district organizations—the $1,000 men.

Major Samuel Klotz, of the New Jersey company, says:

"If I were a councilman in any town I should certainly refuse to grant a franchise to any company that I knew to be the author of such a circular. It is infamous. The idea of a legitimate business concern suggesting the 'greasing of Common Councils' by the 'boys who are in the real pot.' . . .

"We have requested several times to be shown the patents which the Standard Company owns, but have always been put off with one excuse or another by Mr. Nye, the general manager. It has been claimed in certain quarters that no patents existed and that the Standard telephone was a reproduction of the Bell long-distance 'phone. What we want now is to see the patents, to have the parent company build trunk lines as agreed and to have them produce a telephone equal to the Bell and not a fac-simile of it. If we can't have this we want our money back.

"By the list of directors of our company you will see that we have some of the most prominent men in the State, among them Leon Abbett, Gen. William S. Stryker, Gottfried Krueger, P. Sanford Ross and Judge Garretson. We shall not act hastily, but we mean to know just where we stand without further delay."

The New Jersey people have determined to get what they paid for or get their money back—if they can. Judge Abraham Q. Garretson, of Jersey City, a Pennsylvania Railroad attorney, has been appointed a committee of one to investigate and report.

Mr. W. H. Truesdale, of Chicago, says of the circular and other matters:

"The circular is Greek to me. I never saw it before and did not know such a document was in existence. It has a bad look and I can scarcely comprehend its significance. I supposed the company was a legitimate enterprise, and this is the first intimation that I have had to the contrary. . . . . I am astonished at the issuance of such a document. If I had any information to give you I should be glad to give it. I should be glad if I could get some light on the matter myself."

Mr. Robert W. Hunt, of Chicago, is quoted as follows:

"I cannot believe that Mr. Clarkson or any of the leading spirits of the enterprise had anything to do with the issuance of the circular. The document, I say unqualifiedly, is to be denounced. If it was issued with the full knowledge and consent of the men at the head of the enterprise, I admit that it is to be taken as an evidence of dishonesty. I have had faith in the company, however, and still have. I believe the circular emanated from promoters who were bunglers in the art of writing. No business man would issue such a document, and hence I think that the men at the back of the company did not sanction its issuance."

We wonder if Mr. Hunt wants the public to suppose that the greasing of common councils is legitimate but that the plan to do so should not be announced in advance. Other comment from him is in order, and if he will write to us over his own signature he will certainly be correctly reported.

So far as ELECTRICITY has been able to ascertain, and its investigation has been thorough and its information is believed to be authentic, the only telephone exchange plant in the actual equipment of which the Standard Telephone Company has been even remotely interested is the plant of the Citizens' Standard Telephone Company at Kingston, N. Y. The representatives of the Standard Company have stated at Richmond, Va., and elsewhere, when seeking to secure franchises or to make stock sales, that the Kingston exchange is equipped with Standard apparatus and that the local Kingston company is a part of the comprehensive National system of the Standard Company, and that a controlling interest in it is owned by the parent company.

The Citizens' Standard Telephone Company of Kingston was organized in July with a capital stock of $150,000, to do business in the counties of Ulster, Orange, and Greene. The plant of the West Shore Telephone Company, operating at Kingston and adjacent points, was purchased by the Citizens' Company, which assumed all the indebtedness of the West Shore Company.

A large amount of money was spent by the Citizens' Company in rebuilding the lines and extending the service of the Kingston exchange. A contract was made with the Standard Telephone Company for 300 instruments. These instruments were made by the Phœnix Interior Telephone Company of New York, and fitted with "Rose" transmitters at the "electrical department" of the Standard Company, at No. 6 Murray street, New York. One hundred and twelve of these were delivered to the Citizens' Company and installed, payment being made in cash the same as for other supplies purchased elsewhere. The delay in completing the order, and other differences which arose, caused the Citizens' Company to give formal notice to the Standard Company, on October 19, of a cancellation of the order for instruments.

The above described is the only relation which has at any time existed between the Citizens' and Standard Companies. Mr. John H. Farrell, of Albany, one of the most prominent business men of the city, who is a director of the Citizens' Company, stated to a representative of ELECTRICITY a few days ago that—

"The Standard Telephone Company has not, nor has it ever had, one dollar's worth of interest in the Citizens' Standard Telephone Company of Kingston."

The Home Standard Telephone Company of Albany is another organization in which the owners of the Kingston plant are interested. A franchise has been secured and the construction of the plant will be commenced next spring. Like the Kingston Company, the Albany Company has no relation, except that of name, to the Standard Telephone Company of New York.

We demand of the Board of Directors of the Standard Telephone Company of New York an official statement, signed by every member thereof, showing, in clear language, the actual status of the company at present as regards the construction of lines and delivery of the service promised to investors.

This not speedily forthcoming, the entire scheme must be denounced as a fraud and a swindle, no matter whose names have been secured for use in connection therewith.

On whose individual shoulders this charge must rest we leave to the officers of the company themselves to make plain with the progress of events.

DEFECTS OF ELECTRICAL WIRING.

At the Convention of the National Association of Commissioners and Inspectors of Buildings, held in Baltimore, Md., on the 17th ult. Captain William Brophy, chief electrician of the Boston Wire Department, read a paper in which he pointed out many serious defects in the distribution of electrical energy for lighting and power purposes. Much of the paper was devoted to a description of the methods of supplying and distributing this energy. Speaking of the distribution by means of the low-tension underground system he said:

> When, by reason of an accidental reduction of the resistance of the conductors under the surface of the streets, this power, in the form of heat, is concentrated at one point, the copper compound and iron pipe are first reduced to a molten mass; then the paving stones are melted like lumps of fat in a frying pan. A sufficient amount of heat can be produced to cause granite or other stone, supporting posts and pillars to crumble, to heat and melt iron and steel columns, beams and girders, depriving them of all power to support the weight imposed on them, and to quickly ignite the wooden portion of any structure.

Of the alternating current system of distribution, Captain Brophy stated that the division of the energy into a great many small units limits the amount of energy that can be converted into heat in any building; but enough can be produced to cause serious damage if let loose in the right place. In view of the dangers ever present in either system of distribution, Captain Brophy asks:

> What is provided, or used, for keeping this subtle power or fluid, as it is sometimes called, within bounds? Plainly speaking, nothing more or less than cotton or rubber hose, plain or rubber lined, or impregnated with some preservative, non-combustible or insulating compound. The copper conductor in the center of the hose corresponds to the orifice, and the cotton or rubber to the walls of this hose pipe. What would be thought of a man who would propose to use such flexible pipes as this for the distribution of water, steam or gas in any of the buildings you are called on to inspect and approve? Surely you would not look with favor on such a proposition, especially if such pipes were to be placed in the space between floors, ceilings or partitions, where an inspection of their condition would be impossible. Yet hundreds of miles of electric wires are so placed, with nothing but this perishable covering to prevent this subtle fluid from escaping. A large number of these wires are laid on furring, laths and plaster, or are fastened on the side of floor joists and studding, under wooden cleats, the wires separated only 2½ inches from each other. Dry wood is a fairly good insulator, but let it become wet, by reason of the bursting of a water pipe, the overflowing of a sink, set bowl or water closet, and it becomes a conductor; and the same can be said of much of the insulating covering of the wires. Little by little the current finds its way from wire to wire across the surface of the wood, slowly carbonizing it until it bursts into flame. This is one of the cases where the element that is depended on to extinguish fires kindles them, when it is in connection with another element, in this instance, electricity.
>
> It might with propriety be asked why it is that such fragile substances are relied on to hold in check, and for a long term of years, this tremendous force that is capable of performing such great service or doing such an immense amount of damage. The simple answer must be, because nothing better has yet been discovered.

Captain Brophy then states that truth compels him to assert that very little wire can be credited with being reasonably safe when the insulating material has deteriorated. When the wires are laid in channels cut in the brick work, or laid under tiled floors, or imbedded in cement, notice is quickly given of the breaking down of insulation by the refusal of the lights to burn or motors to run. These wires can be removed and replaced by others only by tearing up floors and breaking down partitions and ceilings. The blame for this undesirable state of affairs is due, Captain Brophy thinks, to several causes and several classes of men. In dealing with the causes, he described the manner of wiring buildings for bells, etc., previous to the advent of electric light, and remarked that "improvements have been made in methods and materials since those days, and those engaged in electric construction are ready to provide the best of both when owners, architects and builders have learned that the very best is the cheapest."

> . . . . Those who erect buildings know little or nothing of the quality of electric light construction or material, and, if left to themselves would accept the lowest bid for such work, but when they employ an architect to plan and supervise the erection of buildings, and determine the cost and quality of work and material, they naturally suppose him to be not only competent to make plans and specifications, but to pass on the character of the work during its progress, and when completed as well. I venture to assert that but few of them think it necessary to make any provisions in their plans for electric wires or fixtures, and fewer still know what constitutes a first, second or third class electric plant or outfit.
>
> It is rarely that the contractor finds on his plan the location of the wires and their dimensions, location of lights, fixtures and electroliers, and specifications giving the quality of insulation and character of work, size and conductivity of the installation and the all-important percentage of loss in the wires, and the style and character of the necessary fixtures, number and candle power of lamps, etc., provided by the architect. If the architect has not acquired the practical and theoretical knowledge necessary to enable him to deal with this problem, he should employ some one competent to do so.
>
> In buildings where the wire must be concealed, but for which there are no convenient cavities, a system of conduits is imperatively necessary if the lighting system is to maintain a semblance of reliability, to say nothing of the question of safety. These conduits may be of iron or of other metal, insulated or not. They can be made also of glazed tile or slate that is free from iron or other mineral substances.
>
> The system of interior conduits or the method of fixing the wires to practically indestructible insulators may be adopted in buildings that are not considered fireproof, and ample provision should be made for the conduits when the plans are drawn, and each junction and fuse box located on them. . . . The practice of passing the wires that supply a lamp or a group of lamps through a hole made in the laths and plaster is one that should be discontinued.

Referring to the "reprehensible practices indulged in by those in electric light installations, and approved by architects and others," Captain Brophy said:

> Owing to the lack of faith of electric companies and their managers in their ability to maintain a continuous service, and to the fact that many of the smaller plants did not operate more than a small portion of the twenty-four hours of the day, as well as for other reasons, the combination fixture on which could be placed electric lights and gas burners was introduced. For good and sufficient causes, the continued use of such fixtures should no longer be encouraged. . . . They form a combination that should cause cold shivers to run down the backs of owners of buildings and the fire insurance underwriters, did they know with what ease and grace this twain can kindle the flame that converts the property of the one and the profits of the other into smoke.
>
> No class of men can do more to render this new and powerful servant, now enlisted in the service of man, safe and docile than the competent architects; and they will, no doubt, do their share in that direction when they see the great necessity that exists for their hearty co-operation with those who believe that the dangers attending the distribution of the electric current for all purposes can be entirely removed.
>
> Commissioners and inspectors of buildings should have a general knowledge of electricity, particularly when it is converted into light and re-converted into power. It would be better still if one of the corps of assistants were a practical electrical engineer, thoroughly conversant with the subject in all its phases, and whose judgment could be relied upon and respected.
>
> In cities that have recognized the great necessity of a strict supervision over electric construction, by establishing electrical bureaus or departments, such as those of Chicago, Pittsburg, Philadelphia and some other cities, or the admirably conducted wire department of the city of Boston, this addition to the bureau of inspection of buildings might not be necessary.
>
> I must once more express my firm belief that the transmission of electric energy and its conversion into light, heat, sound and articulate speech, or its re-conversion into motive power, can be accomplished with nearly perfect safety.

A good substitute for gutta-percha is said to be prepared as follows: Tar, one part; paraffin, 10 parts; dissolve together at 120°, and then add caoutchouc, two parts. Keep at this temperature until a homogeneous mass results.—*Electrical Engineer* (London).

ELECTRICITY ON STEAM RAILROADS.

At the twenty-fifth annual meeting of the American Society of Railroad Superintendents, held at the Hotel Brunswick, New York City, on the 14th of October, Col. H. G. Prout, editor of the *Railroad Gazette*, delivered a very interesting address on "The Use of Electricity as a Motive Power on Railroads Now Operated by Steam." The scheme of his talk was to lay down some of the governing principles which would determine where electricity could and where it could not be used; the deduction being that for main line work, as ordinarily understood, it is not to be used; for city work it must be used, while for suburban work and interurban work, it is yet debatable whether electricity or steam may be used. He then gave some idea of the seriousness of electrical competition as already developed, and the gravity of the situation which now confronts the railroad companies in the matter of suburban and interurban traffic, a large share of which must inevitably go to the electric railroads in spite of anything that the steam railroads can do.

It was suggested, however, that there are steps which can be taken by some of the railroads which may prevent the loss of business to competing electric roads. Some railroads, for instance, may be able to equip two tracks for electric operation within their suburban zones on which very frequent and light trains can be run, stopping often. Semi-express trains to serve the more distant suburban points could perhaps be interpolated on these tracks. There are other railroads which may be able to acquire new lines and equip them for electric operation. A great many others can hope to postpone for a little while loss of traffic by giving better suburban service and perhaps lower rates. On some roads accommodations could be made more comfortable for passengers by furnishing better lights, better heating, better cars generally, better facilities at terminal stations, more trains and a quicker schedule. One way of accelerating the speed of suburban trains which make frequent stops would be to insist on greater promptness on the part of trainmen and passengers in getting away from local stations. This is largely a matter of education on both sides—education of trainmen and education of passengers. But after all is done there is a considerable volume of suburban and interurban business that cannot be saved.

There is, however, a set of conditions at work which will change the situation of the present electric railroads a good deal before very long. Up to the present time it has been and still is easy to finance them, because rail mills and electrical manufacturers are glad to help float the bonds of new electric railroad projects; the public is credulous and investors look for great profits. We are, therefore, in the midst of the "kiting" epoch of electric railroads, when bonds which are sold to-day pay the interest on the bonds sold last month or last year. But, naturally, this situation must come to an end before long. It will be hastened by the realization, now at hand, of the fact that more substantial construction must be used than was common in the earlier tracks, that maintenance charges are heavier than has ever been anticipated, that the accident expenses are more than promoters and investors ever counted on, and finally, in some States, by the fact that right of way must be paid for. Furthermore, the States are beginning to exercise control over the building of new electrical railroads. All of these conditions are conspiring to put electrical railroad building on a rational basis and to approximate it more and more to the conditions of steam railroad building.

A gold medal or a premium of 150 florins is being offered by the Dutch Society of Science at Haarlem for a paper on the equilibrium phenomena of one or more alloys of two or three metals ranging from the melting point of the metal most difficult to fuse to the lowest temperature at which the alloy will continue to remain in a liquid state.

THE VARIATION IN THE ELECTRICAL RESISTANCE OF BISMUTH WHEN COOLED TO THE TEMPERATURE OF SOLID AIR.*

BY JAMES DEWAR, M. A., LL.D., F.R.S., AND J. A. FLEMING, M.A., D.SC., F.R.S.

In the course of investigations on the electrical resistance of pure metals and alloys at low temperatures made during the years 1892 and 1893, the results of which were communicated to the *Philosophical Magazine*,† extensive examination was made by us of the variation in specific electrical resistance exhibited by most of the ordinary metals when cooled to temperatures approaching the absolute zero. In the course of this research the abnormal behavior of bismuth with regard to its variation of specific resistance with temperature was noted and in a further research on the thermo-electric powers of metals and alloys at low temperatures, the results of which were communicated to the *Philosophical Magazine* recently,‡ it was noticed that the curves representing the thermo-electric power of bismuth, both for pure and for commercial specimens, presented a discontinuity at temperatures lying between about —70° and —100°. We were therefore recently led to make a more careful examination of the variation of electrical resistance of bismuth when cooled down to the temperature of solid air, some of the results of which are of sufficient interest to communicate, although the investigation is still in progress, and much remains to be done to complete it. A sample of very pure bismuth was kindly prepared for us by Mr. Geo. Matthey, by the reduction of the oxide, an analysis of which showed very small traces of iron as the only impurity. This bismuth, which was the same as that used by us in our thermo-electric experiments, was pressed into wire by a steel press. two sizes of wire being prepared, one having a diameter of about 0.067 centimeter, and the other a diameter of 0.049 centimeter. Lengths of these wires were mounted up in an appropriate form for taking the electrical resistance when measured in liquid or in solid air, or at any other temperature up to +100° C.

Amongst other specimens a wire was pressed from some commercial bismuth, supposed to be fairly pure, which will be distinguished by being called Griffin's bismuth; the diameter of this last wire was about .066 centimeter. The diameters of these wires were carefully measured with a microscope-micrometer in about twenty different places, the lengths of the wire used being about 30 or 60 centimeters. The sample of pure bismuth prepared for us by Mr. George Matthey will be distinguished by speaking of it as Matthey's bismuth, the thicker of the two wires being called A and the thinner B. The dimensions and mean diameters of the pressed wires, which were used just as they came from the press, were as follows:

Sample.	Length. centim.	Mean diameter. centim.
Matthey's bismuth (pure), A......	61.25	0.06713
Matthey's bismuth (pure), B......	32.70	0.04926
Griffin's bismuth.................	52.90	0.06625

In addition to these samples of pressed wires, other specimens were prepared by drawing melted bismuth up into fine glass tubes and making a suitable connection with the bismuth for the purpose of an electrical resistance measurement by means of tinned copper wires melted into the ends of the bismuth specimen. These samples of bismuth then had their electrical resistance measured with a Wheatstone bridge in the usual way, the temperature of the specimen being taken at the same time by means of a platinum thermometer, consisting of a platinum wire closely in contact with the specimen of bismuth. All the temperatures which are given in the following paragraphs have been converted into platinum temperatures, taken in terms of our standard platinum thermometer P_1, the electrical constants of which were given by us in the paper on the thermo-electric powers of metals (see *Phil. Mag.*, July, 1895). Temperatures so measured are distinguished by the letter P_1 placed after the number denoting the temperature. The electrical resistance of the bismuth specimens, all proper corrections being made for the resistance of the connecting wires, was taken at a large number of temperatures lying between the boiling-point of water (100° C.) down to the temperature of solid air, which, in terms of our standard platinum thermometer P_1 is about —233° P_1 to —235° P_1. From the known dimensions of the bismuth wires the volume specific resistance of the metal was calculated at these different temperatures, and the reduced observations for the three specimens above mentioned are given in the accompanying tables.

Commercial Bismuth (Griffin's).

Pure Bismuth (B) (Matthey's).

Volume specific resistance in C.G.S. units.	Temperature in platinum degrees.	Volume specific resistance in C.G.S. units.	Temperature in platinum degrees
	°		°
175,100	+ 49.2	150,600	— 87.9
174,850	+ 48.0	151,300	— 100.5
165,100	+ 18.8	151,300	— 103.9
163,050	+ 11.3	152,000	— 114.8
161,550	+ 3.6	152,850	— 118.8
161,250	+ 1.3	154,950	— 132.2
158,400	— 11.5	155,900	— 136.1
157,900	— 18.3	159,450	— 148.1
153,750	— 36.5	161,200	— 152.2
153,300	— 40.0	166,300	— 168.0
152,350	— 51.6	169,850	— 174.9
152,050	— 55.3	179,550	— 193.4
151,000	— 66.8	181,000	— 196.2
150,850	— 71.0	181,000	— 196.8
150,500	— 83.3	......	......

The above numerical results are set out in the form of three curves (see Plate V). It will be seen that the specific electrical resistance of all the bismuth specimens taken from 100° C. downwards gradually diminishes to a point which in the case of the specimen of pure bismuth "A" was about 50° P_1, and in the case of the specimen "B" about —83° P_1. After these temperatures had been reached, further cooling *increased* instead of diminishing the electrical resistance of the A and B bismuth, until at the lowest temperature reached by the employment of large quantities of solid air, the electrical resistance of the specimen "A" had become increased by nearly 80 per cent. of its minimum resistance, and at the same time the mean temperature coefficient had become very large. and of course negative. It may be noted that the melting point of solid air as determined by our standard platinum thermometer. is —232°.2 P_1, liquefaction taking place under a pressure of 14 millim. of mercury. The boiling point of liquid air under a pressure of 746 millim. is —209°.75 P_1. The same general facts were observed in the case of the specimen of pure bismuth "B," only in this instance the temperature was not taken below about —200° P_1. As regards the commercial bismuth (Griffin's) the curves show that after reaching a minimum point, which for that specimen appears to occur at about 0° C., there is another point of inflection in the resistance curve in the neighborhood of —200° P_1 after which the resistance again diminishes. In the case of each of these specimens the resistance measurements were repeated many times, and in both directions, to obtain an assurance that the relation of resistance and temperature was perfectly definite, and that proof might be obtained that all the three specimens of pressed bismuth wire as well as the bismuth melted in the tubes, did not undergo any permanent change in their condition by the action of the low temperature, but that there was a definite relation between temperature and electrical resistance in the manner shown in the curves.

PRESENT STATUS OF THE AIR-BRAKE.*

BY E. J. WESSELS.

Last October the speaker had the honor to lay before the members of the American Street Railway Association in Atlanta a paper on the subject of "Power-Brakes vs. Hand-Brakes." In that paper reference was made to the advantages of a good air-brake and the desirability of its adoption on roads with congested traffic. high speed or severe grades, and especially where trailers were used.

At that time the street railway air-brake was in swaddling clothes. Some, not positively indifferent on the subject, proved hostile. To contend against this opposition has not been easy.

In considering the present status of the air-brake it is pleasing to notice that the indifference which existed even in influential quarters has largely disappeared. Months ago a prominent railway president asserted that he would not put an air-brake on his road, because if he did there would be nothing for his motormen to do. Since then he changed his mind, and recently contracted to have every car on his road equipped with air-brakes.

Most managers now concede that the old form of hand-brake will no longer answer for heavy, double-truck, high-speed cars. There has been a remarkable change of views since we last met.

There are instances on record where certain roads have contracted for more reliable braking apparatus at a cost which a year ago they regarded prohibitory.

An air-brake which has merely been tested in the *shops* is of doubtful utility. It cannot be depended upon for the rough usage it will encounter in service. No air-brake is fit to be mounted on a car which has not gone through the most crucial tests based on records of similar brakes operated on cars for many months.

---

*Abstract of paper read before the American Street Railway Association. Montreal, October 15, 1895.

To design an air-brake which shall be mechanical, *durable* and economical is one of the most difficult problems a manufacturer can face.

The street car air-brake has much to contend with.

Firstly—The unfamiliarity of the average motorman with the proper use of air is greatly against it.

Secondly—The compressor is begrudged space on the car axle. although generous space is freely given to electric motors irrespective of dimensions. This makes it difficult to have proper bearing surfaces.

Thirdly—The neglect of proper inspection is greatly against the air-brake. Even motors do not receive the attention they should, as many a scrap heap testifies. The air-brake hardly receives any.

Fourthly—Insufficient lubrication. The same man who lubricates his motors passes by the air-brake without using his oil can. Probably he might neglect to oil the motors, but knows that failure to do so would be speedily detected and render him liable to discipline. The air-brake has not reached that point in street railway operation where neglect to lubricate it produces like results. The most perfect apparatus ever designed if neglected cannot do its work properly, and no automatic oiling machinery or mechanism under a car can possibly replace human vigilance.

A year ago the air-brake was not found on many roads. On the few roads where it was being used satisfactory results were obtained, and in the "Street Railway Journal" for March last, in the article entitled "The Street Railway System of Buffalo, N. Y.," a report of the successful operation of air-brakes there will be found. It showed that by using air-brakes there had been a great saving in wheels. As a matter of fact, there should not be any flat-wheels if air-brakes are properly used, for by their aid pressure can be regulated to a nicety.

An examination of the Patent Office records discloses the fact that scores of patents have been granted for mechanical brakes for steam cars, but one would have to travel far to find a solitary mechanical brake in service on steam roads. If they have proved unfitted for steam practice, and the air-brake has been adopted, it is fair to assume that mechanical brakes may not be all that is required for braking electric and cable cars.

The street car air-brake has been adopted by the Australian Government; it has been specified by borough engineers in Great Britain; it is being installed in different places on the Continent. It is, therefore, somewhat discouraging to find that while the street car air-brake receives very careful attention abroad, it is denied that attention here. It is unfortunate that our managers entrust it to uninstructed men who have had no experience in its use.

The air-brake for steam roads has undergone an evolution beginning in 1869. Even its most ardent supporters will not claim that the system as applied to-day is absolutely perfect; but it is commercial and unquestionably has saved hundreds of lives in the past twenty-seven years.

If it has taken that long to bring the present steam car air-brake to a measurable degree of perfection, what may we not hope to see accomplished by the street railway air-brake in a very much shorter time.

The duties required of a street railway air-brake are more severe than those damanded of a steam car air-brake. Even the engineers of the Empire State Express do not face the risks to which the motorman of a fast suburban electric train is constantly exposed. There being no definite time when the train passes crossroads, the motorman of the electric train is menaced by farm wagons and other vehicles, deaf people, bicycle riders and others, who would not attempt to cross the track if the Empire State or other express was due.

The air-brake is the only brake which has an emergency stop that can be instantly applied by the easy turning of a handle. In order to have even an approach to an emergency stop, it is generally necessary with hand-brakes to gear them to a point which they would never reach were the semblance of such a stop not required. This excessive gearing means rapid wearing of parts and needless tiring of muscles.

It is not claimed that the street railway air-brake has reached perfection. It is believed it never will reach that point unless through the co-operation of the railway managers. But even though it is not claimed that the present street railway air-brake is all that it should be, we must admit it has made remarkable strides, that satisfactory results have been produced, and that it is commercial. It will not be possible to overcome all the objections to an air-brake unless managers rally around the men who are striving to reach perfection.

The cry about the trolley slaughter has subsided. Six months ago it had reached large proportions, but the riding public is beginning to realize that even if managers are anxious to minimize accidents they cannot reach the safety point unless a superior class of apparatus is within their reach.

Since we last met, fenders have been made compulsory in several cities. Those who believe most in fenders will not deny that a reliable brake is an absolute necessity. It may be advisable to have both. That is for you to determine. It is probable that air-brakes would have been made compulsory on street railways long ago had the manufacturers of commercial air-brakes devoted their energies to influencing legislation, instead of concentrating them wholly upon the perfecting of an air-brake. It is, however, extremely probable that before long the air-brake also will be made compulsory, and this is a good argument in favor of testing it in actual service *now*, so that if it becomes compulsory managers will be familiar with its advantages.

The claims of the air-brake over other forms of brakes were fully defined in the Atlanta paper referred to and need not be repeated. At that time the electric brake was actively opposed to the air-brake. The opposition has since faded away. There has not been, nor is there, an electric trailer brake. If we are to have a reliable electric motor-car brake, the brake must apply equally well to trailers. Until the advent of an electric trailer brake, the air-brake must certainly be regarded as its superior for *train* service, especially as the air-brake dispenses entirely with brakemen and gives the motorman absolute control of his train.

The street railway air-brake is in a transition state and is going through some of the processes that characterized electric motors. We would not have the superb motors in service to-day had not manufacturers been able to learn the defects of the pioneer motor through the reports and suggestions of their railway friends.

Fenders, car heaters, lighting systems and other things are now going through these same processes. Hence it is not singular that the air-brake shares the common lot.

The questions to be considered are:

Firstly—Are better brakes than hand-brakes necessary?

Secondly—Will not the demand for better brakes grow even more imperative day by day?

Thirdly—Will not some form of power-brake become compulsory ere long?

Fourthly—How can the valve of any brake (mechanical or otherwise) be judged except by tests in everyday service?

Fifthly—How can anything (brake or otherwise) undergo a fair test unless the men who use it are compelled to observe ordinary diligence?

Sixthly—How can any movable machinery or apparatus be expected to work satisfactorily unless the moving parts are kept properly lubricated?

Lastly—Can you afford to operate without having a reliable braking system for checking speed or making service and emergency stops?

If you desire to test an air-brake it will not be difficult for you to secure one, and if perchance it fails to do all you expect of it, it will be an unwise manufacturer who will not avail himself of any suggestions you may make in the light of your own experience. Let us not forget that your interests and the air-brake manufacturer's are and will always be identical.

STORAGE BATTERIES FOR RAILWAYS.

BY MAURICE BARNETT.

In these days when it is the practice of not a few eminent electrical engineers to damn the storage battery in the field of traction, either by too vehement denunciation or by too "faint praise," the announcement in the *Kolnische Zeitung* that the trolley system which has been in use in Hanover for some time has been discarded, and that the twenty-eight cars operated on that system are to be remodelled and equipped with storage batteries, while not conveying solace to the electrical engineers referred to, will prove very gratifying to those who, even in view of some discouraging failures in accumulator traction, have always had a firm conviction that traction work was a legitimate field for accumulators, and that the test of time would prove that storage batteries would be able to hold their own with other representative electric traction systems.

Since the announcement in the *Kolnische Zeitung*, news has been received here that the "Dresden Tramway Company" and the "Hague Tramway Maatschappy" have likewise decided in favor of accumulator traction. Inasmuch as no less important a company than the Tudor Storage Battery Company is making the installation, it is not at all too optimistic to believe in the ultimate success of the storage battery cars about to be operated in the above named places.

Up to the present time, the engineers of the overhead system have had matters pretty much their own way. Occasionally a statement of results (coming in all probability from interested sources) bearing upon the success obtained with the open conduit has caused a commotion in the trolley ranks; but, save for that, the erection of poles has gone merrily on and the manufacturers of trolley machinery have had no complaints to offer on the ground of lack of orders. The past two months, however, have seen the beginning of a mighty change. To-day the trolley is considered to have been merely coincident with the evolution of the modern passenger railway, and that its usefulness in the future, at least in cities, is not likely to be greatly overestimated. E. H. Johnson, who, with Lieut. F. J. Sprague, was the pioneer in working out the trolley method of electric transportation, writing in the *Electrical Engineer* under date of October 9th, sounds the doom of the overhead line at least in cities and towns. The reason for this belief is to be found in the objection to overhead construction, and secondly in the fact that greater economies are possible in the newly projected closed conduit system by reason of the fact that higher voltage may be maintained than is practicable in trolley systems. This criticism, emanating from one of the parents of the overhead wire system, may be considered to have some weight. Mr. Johnson also proceeds to pay his respects to the open conduit system anent the great ado made by the Metropolitan Traction Company of New York "over the practical success of their $150,000 per mile open conduit system," by saying "it was neither scientific nor business like to place the electrical conductors in a sewer and then expend hundreds of thousands of dollars to secure drainage." This represents the view that is at present held respecting the open conduit electric system. Surely the friends of the electric accumulator can take hope in the discomfiture of their rivals!

Looking impartially at this question, it would seem as if the contest for supremacy in the field of transportation would in the future be between the storage battery and the closed conduit systems. Which side will win cannot be conjectured at the present time. Neither system is in the final form it will assume when the contest for supremacy takes place, and one is therefore precluded from indulging in prognostications regarding the outcome.

The above remarks have been called forth by statements appearing from time to time in some of the newer electrical journals, reflecting upon the judgment of those who are instituting the test with storage battery cars on the Madison Avenue line in New York City. The remarks have all been characterized by a sneering incredulity as to the value of accumulators for traction work. Before the next six months are passed, the critics of the storage battery system may have to reverse their conclusions.

The object of the present paper is to emphasize the great value possessed by storage batteries—not in furnishing direct motive power, but when used in connection with railway power plants.

The first accumulators used in connection with a railway power station were, so far as the writer can ascertain, those employed in the power plant of the railway lying between Zurich and Hirslanden, Switzerland, an account of which was published in the *Elek. Zeitung* of June 28, 1894. According to report, the dynamo delivers current under a constant load, the accumulators being charged or discharged as the load on the line is less or greater than the output of the dynamo. In this plant there were automatic means for cutting in and out of end cells to keep the voltage constant. Results showed that by means of the accumulators a saving was effected of 2.2 pounds of coal per H. P. hour, amounting to nearly a ton per day, or $2,500 a year. The cost of accumulators, installed complete with necessary apparatus, was $7,400. Allowing for interest and depreciation, the battery paid for itself in four years by saving in coal bills alone. The saving was effected by reason of there being no necessity to keep a second boiler and steam engine in reserve, and that by this arrangement the power plant ran at its highest efficiency. It was furthermore developed that the first cost of combined steam power and battery plant was less than cost of total steam power plant would have been for the same work.

How important this installation proved may be judged from the fact that a single type of storage battery is now found in Germany and Austria in 80 per cent. of all central stations, besides being installed in fifteen railway power plants and 5,000 isolated lighting plants.

Two railways in the United Kingdom have recently attracted a great deal of attention; and inasmuch as the batteries used in connection with generators are of the Chloride Accumulator type, manufactured by the Chloride Electrical Storage Syndicate, Limited, the installations have a special interest for American railway managers. These two railways are known as the "Douglas-Laxey Line" and the "Snaefell Mountain Electric Tramway," both in the Isle of Man.

The Douglas-Laxey line was established about a year ago. From the September 19, 1895, issue of *Lightning*, London, it is gathered that when the battery was connected to the line the cars immediately began to run with exceptional smoothness, the accumulators keeping the voltage steady and eliminating all sudden variations due to starting of other cars. How variations will otherwise arise will be understood when it is considered that it requires 150 amperes at 500 volts to carry a loaded car up the 8½ per cent. grade at a nine mile rate.

Encouraged by the success attained by the Douglas-Laxey electric tramway, which after a year of service "had fulfilled in every way the expectation of its promoters," it was not difficult to secure capital to construct an extension of this road up to the summit of Mount Snaefell. The electric equipment of the Snaefell road resembles that of the Douglas-Laxey line, both being designed by no less eminent an engineer than Dr. Edward Hopkinson. The battery consisted of 246 special cells. At 550 volts, the battery furnished 176 amperes for three hours, 112 amperes for six hours, 84 amperes for nine hours and 72 amperes for twelve hours.

By evening up the load on the generators, the battery enabled the plant to work at a high efficiency and rendered the service extremely satisfactory.

A large economy is made possible by a special use of battery at seasons of the year when there is comparatively little traffic. Under the agreement with the authorities, these lines bound themselves to run two cars a day each way every day of the year. Obviously, it would not have paid to keep the power house in operation just for this load. This is where the battery proves so valuable during the winter months. The battery being charged once a week can carry the load for the other six days without necessitating the running of the power plant.

In the United States there are two installations of storage batteries in connection with railway power plants which are of special interest. The first is at Merrill, Wis., where a battery of chloride accumulators was installed to effect a solution of the problem so constantly occurring in the railway world, i.e., how to bring up the capacity of the power plant to meet the requirements of a constantly increasing demand. It was decided to use a battery not alone for increasing the light capacity, but for regulating the voltage on the railway circuit, which—according to the engineer who installed the plant—"was far from satisfactory owing to the great fluctuations in railway demand." As the lighting machine and railway generator were connected to the same shaft, it can be understood that the light furnished was far from satisfactory. Records kept before the battery was installed showed a fluctuation as high as nine volts on each side of the three-wire system. Mr. Herbert Condict, in a paper descriptive of this plant read before the Northwest Association of Electrical Engineers at their last Convention, spoke of the performance of this battery as follows: "The great improvement in running of cars was immediately noticed by all, but it was at night that the contrast was most apparent. The two water wheels were connected together as usual, but the railway generator charged the battery at almost a steady rate instead of with its ever varying demand of from 0 to 120 amperes per car. . . . Instead of a succession of sharp peaks the voltage curve of the lighting circuit became practically a straight line; instead of nine volts variation, there was practically no variation, demonstrating most clearly the capability of the battery to respond to all demands of the railway, no matter how severe."

The second plant mentioned is now being installed at Anaconda, Montana, for the Electric Railway, Light and Power Company of that place. The battery consists of 270 special cells of central station type, of 600 ampere hours capacity, but admitting of very heavy discharges. The object of the battery is to even up the load on generators and maintain constant E.M.F. When the battery goes into operation it will be found to give results no less satisfactory than those obtained with the Merrill plant.

To sum up, it may be said that the storage battery is destined to play a very important part in the future in light, heat and power stations. The reason for this statement is to be found in the ability of a good storage battery to act—

First—As a "reservoir" in which may be stored up the energy representing the difference between the average and the maximum demand on a generating plant.

Second—As a regulator of pressure on circuits subject to fluctuating demands, increasing the efficiency of the service and diminishing the wear and tear on apparatus, and

Third—As a "transformer," to utilize high voltage charging currents and to discharge, when disconnected from generator, at any lower voltage desired.

One fact that has been demonstrated, and which has the most important bearing on the construction of electric railway power plants, or for that matter of most electric light and power stations, is that in any station which has to meet a fluctuating demand for power a plant consisting of part steam power and part storage battery is cheaper in first cost than total steam power plant would be for the same work. The high efficiency and satisfactory performance of such a plant has already been referred to.

Edison Is Out.

Finally Dropped from the Pay Roll of the G. E. Company.

About two weeks ago Mr. Edison was notified by Mr. C. A. Coffin, president of the General Electric Company, that his retainer fee of $400 a week would be discontinued at once, but that if he (Edison) was in need of money, the same sum would be advanced to him every week and charged to his account.

Mr. Edison did not accept the situation cheerfully, but at once called on J. P. Morgan & Co. and expressed himself with some emphasis. It was finally decided, we believe, to place him upon the pay roll of the Edison Illuminating Company of New York for an equivalent amount, for services rendered in years past.

Brooklyn Electrical Society.

The latest appliances for the measurement of electrical resistance was the subject of an interesting lecture delivered by Mr. Otto T. Louis, of the Queen Company, before the Brooklyn Electrical Society on Tuesday evening, October 29, in the Edison Assembly Rooms, Brooklyn.

Mr. Louis described at length all the more important resistance testing instruments in their process of manufacture, also a new form of American standard, which is an improvement on the British Association unit. The lecturer also described and exhibited a new bridge capable of measuring resistances as low as that of ¾" bar copper. At the close of the lecture Mr. Louis made several donations to the Society.

The Henry Electrical Club.

At the weekly meeting of the Henry Electrical Club, held at the American Institute, New York City, on the evening of the 1st inst., Dr. M. I. Pupin, of Columbia College, gave a lecture on "The Alternator." The history of the development of this type of dynamo-electric machine, the theory of its design and its characteristics were considered at some length. The lecture was illustrated by diagrams and was appreciatively received by a larger number of persons than usually attend the meetings of the Club.

General Electric's Financing Policy.

Northwest General Electric—The Scheme, the Companies Financed, the Facts and Figures from the Official Record.

How Bonds are Manufactured for New England Investors.

CHAPTER XVI.

The Austin Electric Company.—II.

The official records of the Austin Electric Company, published in our last issue, it will be remembered, showed a deficit for the year ending March 31, 1893 of $4,733.15, which was constantly increasing up to December 1, 1894, the date of the last report. The plant was under the direct control of the Northwest General Electric Company, was for the most of the time in the hands of an admirable central station manager, and it is certain that the best possible record was made.

It is sufficiently proved, therefore, that there was no earning capacity on which to base a capitalization as was planned by Mr. Byllesby, of $100,000. The debt to the Northwest General Electric Company had increased from $401.30 on March 31, 1893, to $7,586.16 on March 31, 1894.

Now let us see what basis there was in actual plant for the capitalization. We present herewith the official inventory of the company's property, with the most liberal valuation to be placed upon it:

AUSTIN ELECTRIC COMPANY, AUSTIN, MINN.

SCHEDULE OF PROPERTY: APRIL 1, 1893.

(Photographs and Plans on File.)

REAL ESTATE.	
Lot 1, block 33. Brick station, including engine and dynamo room, 39 ft. 2 in. x 46 ft.; boiler room, 39 ft. x 36 ft. 4 in. Frame building (former station), 50 ft. x 20 ft. Frame building, coal shed, 40 ft. x 12 ft. 6 in., 7 ft. x 10 ft. high.	$2,500.00
STEAM PLANT.	
One Ball single cylinder engine, 12 x 12. One Ball tandem compound engine, 9 x 16 x 12. Two H.T. boilers, 60 in. x 17 ft. 3 in., 64 4-in. tubes. One Globe injector. One 100 H.P. heater, Wainwright imp. cop. tubes. One Reynolds heater, 100 H. P. (old). Piping, valves, etc.	$5,235.00
BELTS.	
Two leather belts, 39 ft. long x 7½ in. wide. One " " 51 ft. " x 7½ in. " One " " (old). Two " " "	$236.80
ELECTRIC PLANT.	
One K. 12 arc dynamo, No. 2,289; capacity 30 1,200 C. P. lamps. One L. D. arc dynamo, No. 3,932; capacity 50 1,200 C. P. lamps. One A. 35 alternating dynamo, No. 591, 110 volts; capacity 650 16 C. P. One A. 35 alternating dynamo, No. 500, 100 volts; capacity 650 16 C. P. One D.S. exciter dynamo, No. 2,447, 110 volts, 20 amperes. One D 1½ S exciter dynamo, No. 3,678, 110 volts, 10 amperes. One oak switchboard, 6 ft. 6 in. x 8 ft. 6 in.	$4,982.50
INSTRUMENTS.	
Four Type A lightning arresters. Four Type F lightning arresters. Four feeder blocks, No. 8,170. Two current indicators. Two potential indicators. Two station transformers. Two rheostats, Type 148, No. 12,598 and 13,004. One " " 165, No. 15,912. One " " 141, No. 14,766. One one-circuit ground detector. One Thomson-Rice ammeter. One buckle switch. Two 75 ampere station switches, D.P. D.B. D.T. Six 10 " " " D.P. D.B. D.T. One two-circuit arc plug switchboard.	$790.50
ARC LAMPS.	
52 K. 12 arc lamps. 4 hoods for arc lamps. 82 clear arc globes. 19 opal arc globes.	$1,086.60
POLE LINES (ERECTED).	
139 30 foot poles; 2 50 foot poles; 154 4 pin cross arms; 22 2 pin cross arms; 156 brackets; 589 D. G. insulators; 186 porcelain knobs; 383 1½ in. oak pins; 8,130 ft. No. 4, 6,180 ft. No. 6 and 9,388 ft. No. 8 B. & S. weatherproof wire; 9,210 ft. No. 8 Underwriters' wire; 1,720 ft. No. 12 B. & S. weatherproof wire; 670 ft. No. 10 and 1,280 ft. No. 14 K. K. wire	$1,985.10
TRANSFORMERS (ERECTED).	
23 B 15 (one burned out); 5 B 25; 3 Class A; 4 E 1; 6 E 2; 2 E 8; 1 E 8; 1 F 4,500 watts; 1 F 1,250 watts; 5 F 1,000 watts; 4 F 600 watts; 8 F 300 watts.	[illegible]

Brought forward	$20,112.30
METERS.	
Sixty 10, twenty-four 15, seven 25 and one 50 ampere wattmeters; one 40 and three 20 ampere, Westinghouse.	$1,096.00
TOOLS AND FIXTURES.	
One 8 in. square; 2 pair pliers; 1 pair splicing clamps; 3 screwdrivers; 2 compass saws; 1 *hand* saw; 1 hand axe; 1 pair climbers; 1 gasoline torch; one long handle spoon; 2 long handle shovels; 1 digging bar; 1 pinch bar; 2 raising forks; 1 tree trimmer; 1 chain *tongs;* 150 ft. manilla rope; 1 set double 2 in. pulley blocks; 100 ft. ½ in. rope with come-alongs; 2 sets double 2 in. pulley blocks; 1 set triple pulley blocks; 150 ft. ¾ in. rope; 1 *10-foot* step ladder; 1 8-foot step ladder; 1 pair extension ladders; 1 coal pick; 1 pick-axe; 1 iron wheelbarrow; 3 scoop shovels; 1 flue cleaner; 2 hoes; 1 splice bar; 2 bellows; 1 speed indicator; 4 oilers; 2 ½ gal. measures; 1 oil filter; 10 drip pans; 2 oil cans, 1 and 3 gallons; 1 clock; 1 10-in. grindstone; 1 magneto; 1 stove; 1 75-foot tape line; 4 iron pulleys, 3 12-in. diam., 10-in. face, 1 16-in. diam., 8-in. face; 10 engine wrenches; 25 ft. canvas hose; 1 12-in. combination wrench; 3 monkey wrenches; 1 pipe vise; 1 bench vise; 1 ratchet brace; 2 expansive bitts; 1 reamer (for tapping oil barrels); 1 machinist hammer; 1 20-in. Stillson wrench; 1 adz-eye hammer; 3 files; 2 cold chisels; 1 office desk; 2 office chairs; 1 office stool; 2 common chairs; 1 slate; 1 wardrobe; 1 set shelves; 1 counter scale; 1 platform scale; 1 water meter; 2 piston wrenches.	$326.60
INSIDE WIRING MATERIAL.	
52 K. W. porcelain rosette cut-outs; 45 keyless T.-H. sockets; 31 key T.-H. sockets; 6 keyless wall sockets; 36 D. P. D. B. 20 amp. porcelain cut-outs; 4 D. P. D. B. 10 amp. porcelain cut-outs; 17 S. P. 5 amp. porcelain cut-outs; 1 40 amp. D. P. snap switch; 1 30 amp. lever switch; 11 10 amp. Paiste switches, porcelain base; 5 5 amp. Paiste switches, porcelain base; 5 25 amp. Paiste switches, porcelain base; 1 10 amp. S. P. switch, T.-H., porcelain base; 8 30 amp. D. P. M. L. porcelain cut-outs; 2 lbs. black Grimshaw tape; 1 lb. white Grimshaw tape; 2 lbs. Okonite tape; 21 Ball cord adjusters; 4 8-in., 7 5-in. and 2 7-in. opal shades; 6 snowball opal shades; 7 ruby shades; 31 2¼-in. and 34 3¼-in. shade rings; 28 arc lamp clutches; 4 gross 1½ in. x 8 in., 5 gross 1 in. x 8 in., 2 gross 1¼ in. x 8 in., 1 gross 2½ in. x 16 in., and 4 gross 3 in. x 14 in. flathead brass screws; ½ gross 1 in. x 10 in. R. H. blued screws; 186 small porcelain knobs; 17 attachment plugs; 25 peanut cord shorteners; 108 rubber bushings; 45 break knobs; 45 D. G. insulators; 20 large porcelain knobs; 60 medium porcelain knobs; 177 ceiling buttons; 100 ⅛ in. and 50 ¼ in. patent cleats; 2¼ lbs. wire solder; 12 hard tubing; 58 lbs. No. 14, 4 lbs. No. 12 and 27 lbs. No. 10 K. K. wire; 49 lbs. No. 8 and 82 lbs. No. 6 weatherproof wire; 53 lbs. No. 10, 50 lbs. No. 12 and 61 lbs. No. 14 Underwriters' wire; 124 lbs. old wire; 106 16 c. p. lamps; 24 32 c. p. lamps; 57 lbs. galvanized iron wire, No. 8; 30 1½ in. oak pins; 20 brackets; 45 D. G. insulators; 20 large porcelain knobs	$124.20
STATION SUPPLIES.	
27 gals. kerosene oil; 16 gals. engine oil; 12 gals. cylinder oil; 24 lbs. cup grease; 25 tons Wilmington coal; 4 tons unscreened nut; 42 lbs. colored cotton waste; 26 lbs. white cotton waste; 2,250 carbons.	$147.00
Total	$22.106.10

Again, we submit, we have presented undeniable proof, as in the case of all other Northwest properties analyzed. of the truth of the charges so often made in these columns, that the entire career of the Northwest Thomson-Houston and General Electric Companies, as directed by Mr. C. A. Coffin, and carried into execution by Gilman and Byllesby, was little less than a confidence game—a studied and elaborate attempt to manufacture worthless securities to sell to savings banks, trust companies, and directly to small and comparatively poor investors in the East.

Mr. Coffin's direct connection with all these evil schemes has not been denied. . It cannot be. In the case of the Austin plant no proof is lacking. With the records all before him, with a full knowledge of the disastrous career of the plant from the start, with the official inventory in his own desk showing the total possible cost of the equipment to be not over $23,000, he stated, over his own signature, only a a few months ago, that the plant had cost $53,595.58. Perhaps it did cost the Northwest General Electric Company this amount. If so, at least $30,000 was stolen by those who had in charge the manipulation of the Austin Company's accounts.

General Electric.

(From the Boston News-Bureau.)

General Electric business is now said to be at the rate of about one and a quarter millions per month, though some months have been as high as a million and a half. It is not expected, however, that the General Electric gross business will be over $15,000,000 this year. The company will this year endeavor to write off its entire patent account, and not more than 3 per cent. need be expected as the exhibit of earnings on the common stock.

It is understood that the Northwest General Electric Company, whose preferred stock sold at from $90 to above $100 per share in this market a few years ago, has been closed out and wound up, and the preferred stockholders got from the guarantee of the General Electric Company about $10 per share. The other 90 per cent. they can charge off to profit and loss.

Some of the most sagacious investors in Boston failed to foresee the overturn that has taken place in the great Northwest territory. Electric railways in this district whose bonds were bought by New England investors at about par have not only failed, but the rails have been taken up and sold for scrap iron, returning the bondholders a small percentage on the dollar.

BOOK REVIEWS.

COMPRESSED AIR. Practical Information upon Air Compression and the Transmission and Application of Compressed Air. By FRANK RICHARDS, Mem. A. S. M. E. 8vo, cloth. 195 pages. New York: John Wiley & Sons.

The matter contained in this book, or at least the most of it, appeared from time to time in the columns of the *American Machinist*, and has been gathered together here to meet a supposed want for a condensed and handy statement of the case of compressed air. The want is certainly existent, for the literature of compressed air is almost wholly confined to scattered articles in periodical publications, to a few chapters in the larger works treating of tunneling and mining and to the circulars of manufacturers of air-compressing machinery. The last is perhaps the fullest of all, but, as the author suggests, is open to the implication of partisanship.

In opening this book we were elated with the hope that at last there had been presented a treatise that was full and from a non-partisan standpoint. We also hoped to find the subject handled in an able manner. Our hopes were founded on the interested basis that as compressed air transmission has been the last to give way to the electrical—and in many applications has not yet given way—we wished to see clearly stated its points of vantage so that the discrepancies of the electrical method might become more manifest. We confess that we were sorely disappointed in the first chapter. The author seems to take the stand that economy is not one of the essentials and that convenience alone is the recommendation of the medium about which he writes. It is certainly true that convenience will often overbalance a considerable lack of economy, but we were unprepared for such a candid acknowledgment of the greater cost of compressed air over other methods as the author makes. He says (p. 6): "The application of the air is not mechanically economical, only *ten per cent.* of the power employed being applied to the work of moving the carriers, while ninety per cent. is 'wasted' in accelerating the air, and in its friction." This in regard to pneumatic tube transmission. This means, if we assume an efficiency from the fuel to the engine piston of 10 per cent. an ultimate efficiency of but 1 per cent., and the argument is used to show that actual power economy has little to do with the employment of compressed air. We think that the illustration is an unfortunate one for his audience, who are evidently laymen, for they will conceive that "power economy," as he expresses it, is a secondary consideration, whereas nowadays it is in most applications a prime requisite.

He says: "Compressed air is *unique* [italics ours] among all power transmitters—at least among *long-distance power transmitters* [italics again ours]—in that it is always and instantly ready to do its work to its full capacity, and yet it charges nothing for its services except when it is actually employed." This is a rank misstatement of fact, for any means of storage of energy fulfils equally well this specification. A compressed spring, water pumped up to an elevated reservoir, or any other weight raised against gravity, thermal storage, gas storage, many forms of chemical reactions, etc., etc., which absorb energy in their initial stages are capable of being reversed quite as well as the compression of air. Unfortunately electrical energy is not capable of storage of this kind, and when the so-called storage of electrical energy takes place, it does involve a charge for its services, but this charge is by no means as great as the author seems willing to admit for compressed air in the way of inefficiency. As a further argument for the use of compressed air he says: "These uses of compressed air . . . continually increase, not because the air is more adapted to . . . use than any other, but because the *air* is *there*." If that argument is good, and we don't think it is, the argument for electricity would be better, viz., that the ether which pervades all space and upon which alone it is dependent, is more universally "there" than air.

His heresy, however, is that mere convenience overbalances all other considerations. In speaking of a plan adopted by a master mechanic of a certain railway company for whitewashing by means of compressed air, he concludes thus: "There can be no doubt of the success of this scheme; but if it pays to use a locomotive, a freight car, three brake pumps, two reservoirs, and all the rest of it (system of piping into the building and men to hold the nozzles), for such a job, compressed air surely must be cheap at any price."

In the first place, we think it would be difficult to prove that the method outlined above would be more economical than hand labor, and the author does not attempt to prove it, but says that *if* it pays to employ that method, then "compressed air surely must be cheap at any price." It would be a great concession to admit that such a method would pay, but admitting for the moment that it would pay it is a *non sequitur* that compressed air would be cheap at *any price*.

We are led into this somewhat lengthy review of this book chiefly because of the publishers' name, which usually stands for merit. In this instance we think they have been sadly mistaken, for however able the author in everyday affairs of life, he seems to have mistaken his calling when he felt called upon to write a book in defence of compressed air.

The ill impression which we formed on reading the first chapter followed us throughout the work. In justice to the author, however, we must say that he has collected much information of a valuable character and presented it oftentimes in a very attractive form for the novice. His exposition is entirely elementary and usually diffuse, but that is not a fault (unless carried too far) when catering to the layman. His fault lies chiefly in the doctrine that efficiency is not an essential in present day engineering.

GAS, OIL AND AIR ENGINES; OR INTERNAL COMBUSTION MOTORS WITHOUT BOILER. By BRYAN DONKIN, JR. Cloth, 8vo. 409 pages, 136 illustrations. London: Charles Griffin & Co.

The gas engine, while it has come into considerable use abroad, is but little known in this country, chiefly because of the business stupidity of those into whose hands its manufacture has so unfortunately fallen. The merits of internal combustion engines, however, deserve to be more widely known, and every well conceived effort to place this knowledge before the public is welcome and appreciated.

The present work is, we believe, the fullest treatise yet published, and coming as it does from one who is regarded as an authority on such subjects, is particularly welcome.

We are sorry to see, however, that in many particulars the author has not brought his book up to recent times. For instance, in his description of the Daimler motor, which is now so interesting on account of its recent successful application to automobile vehicles, he is away behind the times. He is evidently not familiar with the present mechanism and has not taken the trouble to obtain recent data. This criticism applies also to many other portions of the book, and we are surprised that a man of Mr. Doukin's standing would be willing to come before the public so illy prepared on so many subjects to do them justice.

The book is divided into three parts, treating respectively of Gas, Air and Oil Engines. Part 1, Gas Engines, is divided into two sections, the first dealing with the early history of these motors, and the second with modern gas engines. The theory of the gas engine is discussed in four chapters. The chemical composition of gas is given one chapter. An appendix is added in five sections in which much valuable data not otherwise readily accessible have been incorporated, and tests on gas, oil and air engines, showing the results accomplished to date, will be found valuable for reference.

Short descriptions, often illustrated, of the various makes of English, French and German engines are given, making this undoubtedly the most complete exposition of the art yet offered.

The various methods of producing fuel gas are also briefly described. We would like to have seen this portion of the work largely amplified, and consider that its brevity in this direction is a great mistake.

The author, however, has been very painstaking, and the merit of what he has given us is what especially emphasizes the want of that which he has omitted or slighted.

LEGAL NOTES.

In the case of the electric railway companies of Harrisburg, Pa., versus the city, in which the companies resisted the payment of taxes on cars not in general use, Judge McPherson has decided that the act of 1889 makes no exception of this kind, and holds that the city is authorized by its provisions to impose the tax of $55 on any car that has been used in the city during the year.

Argument in the case of the New Britain, Conn., electric road was concluded in the Supreme Court on the 25th ult., and the decision of the court is awaited with interest as it involves the question of the right of a town to take a certain per cent. of the receipts of street railroads for the privileges granted. The matter has never been passed on in Connecticut.

The Montreal (Can.) *Gazette* states that the Superior Court has issued an order for the winding up of the affairs of the St. Jean Baptiste Electric Company. Charles Desmarteau has been appointed provisional liquidator and Judge Ouimet will hear further proceedings on the 7th of November.

The General Electric Company has begun suit in Tacoma against Receivers Bird and Mitchell of the Tacoma Railway and Motor Company, to restrain them from paying interest coupons on first mortgage bonds of the company issued April 1, 1890. The Farmers' Loan and Trust Company, Miles C. Moore, the Baker-Boyer National Bank of Walla Walla and the Pacific National Bank of Tacoma are made defendants.

Married.

On Wednesday afternoon, October 30, at Delmonico's, Mr. Joseph Wetzler, editor of the *Electrical Engineer*, and Miss Pauline, daughter of Mr. Jacob Gerson, were married by the Rev. Mr. Silverman. Mr. Wetzler and bride are at present on an extended tour of the various Southern resorts.

Mr. L. J. Montgomery, secretary of Electricity Newspaper Company, and Miss Mary Helen Watt, youngest daughter of Dr. Thomas Watt, of Kintore, New Brunswick, Canada, were married on Thursday, October 31, at the residence of Mr. John Nicol, Jersey City, N. J.

Personal.

Among out-of-town visitors to the metropolis last week were Henry Cram of the Bernstein Company, Boston; B. E. Sunny of Chicago, Dr. Addison of San Francisco, Charles King of the Ohio Brass Company, Mansfield, O., and H. E. T. Pringle of Montreal.

Mr. and Mrs. W. S. Key, of Boston, were guests of friends in Brooklyn last week, stopping off on their return from a Southern trip.

Mr. Eugene McQuat has succeeded Mr. E. E. Cary as superintendent of the Beacon Lamp Company's factory, Boston.

GENERAL NEWS.

What is Going on in the Electrical World.

Park Rapids, Minn.—An electric light plant will be put in here in the spring.

Arcadia, Wis.—The Arcadia Milling Company will put in an electric light plant.

Atlanta, Ind.—It is proposed to organize a local company to light the town with electricity.

Tunkhannock, Pa.—It is planned to construct an electric railroad from Scranton to Tunkhannock.

Allegheny, Pa.—The new electric light plant installed by the Western Electric Company has been completed and the lights turned on.

Little Valley, N. Y.—The taxpayers of the village have voted in favor of an issue of $7,000 bonds for the purpose of putting in electric lights.

Reading, Mass.—The selectmen have decided to grant a franchise to the Woburn & Reading Street Railway Company for an electric road to Woburn.

Preston, Minn.—An election has been held here to ascertain whether an electric light plant and waterworks should be put in. The vote stood 151 in favor to 58 against.

Topeka, Kan.—The council has passed a resolution instructing the city clerk to advertise for bids for machinery to increase the capacity of the city electric light plant.

Bloomfield, N. J.—Work has just been begun on the extensions to the Sprague Electric Elevator Works in Bloomfield, one of which will be 125 x 100 and the other 200 x 64.

Tarrytown, N. Y.—A. J. McKee, of Tarrytown, has filed an application with the board of trustees for the right to construct and maintain an electric railway in the village.

Cincinnati.—The Cincinnati Street Railway Company intends to equip its "owl cars" with electricity and run them at shorter intervals; the cars are at present drawn by horses.

Peterboro, Can.—The first three-phase electric plant erected in Canada is being put in in the town of Trenton. It is proposed to run electric wires to Belleville, Can., twelve miles distant.

Philadelphia.—At the Baldwin Locomotive Works three electric freight engines are being constructed, two of which are to be used for switching purposes and the other is to be placed on exhibition.

Corunna, Mich.—At a special election held here on the 24th ult. the proposition to bond the city in the sum of $30,000 for waterworks and an electric light plant was carried by a large majority.

Jamestown, N. Y.—The council having decided to furnish electricity for commercial lighting, have accepted the estimates of the Standard Electric Company of Chicago for additional machinery for the city plant.

Davenport, Ia.—The gas and light committee of council and the board of public works have been ordered to advertise for proposals for lighting the city by electricity for a term of five years, commencing June, 1896.

Norwalk, Conn.—The Tramway Company of Norwalk, whose charter gives it the privilege of building a trolley line from Norwalk to New Canaan, has made a preliminary survey over the main road between the two points.

Aberdeen, Wash.—The electric light plant has been leased to the firm of Benn & Green of this city for a period of one year with the option of two years. The purchasers promise to extend the lines and give an all-night service.

Albany, N. Y.—The Buffalo Traction Company, whose incorporation papers have been filed here, intends to construct a surface electric railroad sixty-six miles in length, crossing the city and extending into various suburbs of Buffalo.

Rutherford, N. J.—The borough council has revoked the franchise giving the Union Traction Company permission to build an electric road through this town on the ground that the company had not begun construction within six months as required.

Winnipeg, Man.—The Neepawa Electric Light and Power Company, Limited, is applying for a charter of incorporation. The capital stock is $20,000. Directors: J. J. McFadden, J. H. Hamilton, J. H. Dandson, J. H. Howden, G. A. Davidson, all of Neepawa.

Springfield, O.—The county commissioners have granted to the Dayton, Springfield & Urbana Railway Company a franchise to construct an electric line over the National and Valley pikes from the west corporation line of Springfield to the west county line near Medway.

Lansdale, Pa.—The "Republican" says: "There are rumors afloat to the effect that another electric light and power company is about to be formed in Lansdale, with a view of furnishing electric power to operate a trolley line from Lansdale to Doylestown and Norristown."

Mankato, Minn.—C. L. Alleman, manager of the Standard Oil Company's business here, and S. R. Snow, proprietor of the Saulpaugh Hotel, are considering the advisability of operating an electric street railway and lighting system here, and will ask the council for a franchise.

South Haven, Mich.—The business men and fruit growers of this vicinity are agitating the building of an electric road from Saugatuck to Benton Harbor. Many of the fruit growers between here and Saugatuck are anxious for the construction of such a road, and will give the right of way.

New London, Conn.—Interest is revived in the projected electric railway between this city and Norwich, and indications are favorable to the carrying out of the scheme. The selectmen of Waterford and Montville have designated a route for the railway over the highways of their respective towns.

Shaefferstown, Pa.—Local moneyed men have subscribed nearly $45,000 for the extension of the Reading & Womelsdorf Electric Railway to this place. The estimated cost is $80,000, which would include the necessary equipment. The line is in operation to Womelsdorf, fourteen miles west of Reading.

Niagara Falls, N. Y.—W. W. Gibbs, president of the Electric Storage Battery Company of Philadelphia, has been here making investigations with a view, it is stated, to establishing a great factory for storage batteries in this locality. He said the prospects of the company locating here were very favorable.

Wabash, Ind.—The county commissioners have granted the recently organized Huntington, Columbia City and Ligonier Electric Railway Company a franchise for the construction of its line through Huntington County. The road is to be forty miles long and taps the finest summer resort region in Indiana.

Danville, Va.—The charter of the Dan River Power and Manufacturing Company has been amended by action of the Hustings Court so as to make the limit of capital stock $1,000,000. It was originally $750,000. This company is developing the water power in Dan River, four miles above here. One of the first enterprises to be inaugurated will be an electric plant.

Wilkinsburg, Pa.—Sealed proposals will be received until the 16th inst., by James G. Stover, borough clerk, for the furnishing and lighting by electricity of 65 arc lamps, more or less, of 2,000 c. p., on the streets of the borough, to be located as council may direct. Proposals must be accompanied by a certified check for $1,000 as surety that if the proposal be accepted a contract will be entered into.

Washington, D. C.—Among the improvements lately made at the Capitol was the installing of a complete electric lighting plant capable of furnishing illumination for the whole building. The odors of escaping gas had rendered the atmosphere of the halls and chambers almost unbearable, and it was decided to abolish the deleterious illuminant and give the nation's legislators better air and better light.

Boston, Mass.—The common council has adopted an order looking to the presentation of a petition to the Legislature for the passage of an act enabling this city to adopt a municipal lighting system. The council was asked for a hearing on the subject by the Boston Electric Light Company and the Edison Electric Light Company, and a date for a public hearing was set for November 14 at 2 P. M.

Terre Haute, Ind.—The stockholders of the proposed Terre Haute & Brazil Electric Railway have elected the following board of directors: Christian Miller, James N. Halstead, Major Collins, Max Joseph, Frank E. Benjamin, R. J. Smith and J. N. Hickman. The directors elected Max Joseph president, W. H. White treasurer and R. J. Smith secretary. The directors ordered an extra assessment called at once.

Harrisburg, Pa.—The Harrisburg & Mechanicsburg Electric Railway Company, having failed to obtain consent of all the municipalities through which the line was projected prior to the recent decision of the Supreme Court requiring such consent, has determined to change its route. The parts of the route abandoned are the extensions to Oyster's Point, Shiremanstown, Mechanicsburg and Riverton. The line will be operated to West Fairview and New Cumberland.

Fond du Lac, Wis.—The General Electric Company has taken its dynamos and other machinery out of the local electric light plant on an execution rendered in June last. It is reported that the owner of the plant, Elihu Colman, has closed a deal whereby the entire property of his company—the Fond du Lac Light, Power & Railway Company—has been transferred to other parties who will reorganize the company and put in the best electric machinery to be found in the market.

Lynn, Mass.—It seems probable that the General Electric Company will have to shut down its works here owing to the strike of the moulders. A careful estimate of the number of employees of the works who have been suspended because of lack of work pending the settlement of the strike is placed as high as 150, and it may possibly reach the 200 mark. This would make the total number rendered idle by the strike about 300, and in many departments of the works the operatives are working but three days a week.

Petersburg, Va.—It is understood here that operations will be commenced shortly on the electric road connecting Manchester with Petersburg, for which J. C. Robertson, of Manchester, has obtained a franchise. Mr. Robertson says that he intends to have motors on the cars of sufficient power to carry several extra cars whenever it is necessary to attach them as trailers. In addition to passenger coaches provision will be made for carrying freight and express.

St. Louis.—The Laclede Power Company, St. Louis, has increased its capital from $75,000 to $400,000. As the new capital was contributed by men in the company there will be no change in officers or directors. President Henry C. Scott of the company said to a reporter lately: "We have about 1,000 miles of wire, but most of it is in the heart of the city and we want to extend our lines. We will endeavor to convince manufacturers and others that it would be economical for them to dispense with their steam plants and to get their power from our central station."

Danbury, Conn.—A company to be known as the International Electric Company has been formed here to control the electric railway system invented by J. M. Murphy and Albert F. Pierce, of this city. The following are the officers agreed upon: President, Samuel H. Rundle; vice-president, J. H. Hawkins; second vice-president, G. V. P. Lansing; treasurer, G. Mortimer Rundle; secretary, Albert F. Pierce; general superintendent, J. M. Murphy; directors: Samuel H. Rundle and G. Mortimer Rundle, of Danbury; J. H. Hawkins and G. S. Hawkins, of Steubenville, Ohio; G. V. P. Lansing, of Seattle, Wash.: George A. Shepard, of Bethel; Albert F. Pierce and J. M. Murphy, of Danbury; W. J. Dickson, of Canada, and Alfred Adams, of Cleveland.

Brooklyn, N. Y.—Chief Engineer C. C. Martin has been instructed by the Bridge trustees to advertise for proposals for an electric system for switching the Bridge cars. The bids will be opened at the regular meeting of the trustees on the 11th inst.—William E. Roller, of the electrical department at the Brooklyn Navy Yard, has devised an electrical arrangement for signaling at sea which will shortly be tested and if found practicable and efficient will be adopted on all the ships of the United States Navy. The system consists in electrically illuminated letters formed on a frame by an arrangement of parts calculated to facilitate their successive production. The keyboard is built after the fashion of a typewriter and can be operated from the cabin or any convenient part of the ship.—The common council has passed a new franchise to take the place of the one already granted to the State Electric Light & Power Company, some of the provisions of which were either unconstitutional or could not be carried out by the company. The new grant provides for a forfeiture of all moneys paid into the city treasury by the company.

Chicago.—The Suburban Electric Railway Company has secured a franchise from the trustees of the town of Riverside, thus completing the right of way of this company. The Suburban will connect a number of the small towns between Chicago and La Grange.—In view of the opposition of the property owners to the proposed overhead trolley railway in Indiana avenue, the General Electric Railway Company offers to maintain the underground system in operation in the avenue for one year, when, if satisfactory, it can be purchased by the City Railway Company (the projector of the trolley line) at a figure not to exceed $19,000 per mile.—Tests of a new automatic electric signaling service have been made on a section of the Chicago and Eastern Illinois Railroad which appear to have been quite successful. It was shown that the system will give timely alarm to the engineer of a moving train when approaching a standing or moving car or locomotive on the same track, and of an occupied grade crossing, an open switch or drawbridge, or a car projecting from a side track over the main track. As the signal given is the ringing of a bell in the cab of the locomotive, which will continue to ring until stopped, the system is certain to be as effective in darkness as in daylight. The device is the invention of E. B. Cornell, formerly with the Cramps in Philadelphia.

TELEPHONE AND TELEGRAPH.

Will Not Give Franchises Away.

The Duluth correspondent of the Minneapolis *Journal* says: "It is not a sure thing—this trying for a telephone franchise in Duluth. The people have come to regard the giving of franchises in an unfavorable light, even when strong inducements are held out. Only a short time since the council refused to give a telephone franchise to a new company on the ground that they didn't want two systems in conflict, as the service would be unsatisfactory to the public, and also because they wanted to be able to reap a decided advantage for the city when the present company's franchise expires, which date is not far distant Later the council refused to give the present company an extension although it offered some return in a financial way. When the franchise expires the privilege will probably be sold to the highest bidder."

Willing to Sue in Massachusetts.

It will be remembered that some time ago the Manhattan Electrical Supply Company of New York published a card offering to pay $100 for the privilege of defending a suit on the Berliner patent brought by the Bell Company against any user of the Manhattan Company's telephones. Some days ago an agent of the Bell Company visited the Manhattan Company's office to inquire if the $100 reward would be paid in case a suit were instituted in Massachusetts. He was advised that it would not, but the amount would be increased to $500 if New York be selected as the battle ground.

Telephone Kiosks.

The extension of the telephone booth idea is to be made in Copenhagen. A company of leading Danes has been formed to erect in all the public squares of the city telephone kiosks, which will be capacious and elegantly fitted up. Here, besides the telephone, the citizen will have access to the daily papers, be able to write letters, receive messages, have their shoes polished and generally to make themselves comfortable.

To Use Rails As Wires.

It is proposed to connect Aberdeen and Tacoma Park, South Dakota, by running a telephone wire to a rail of the Great Northern Railroad, at Tacoma, and making a similar connection at the Aberdeen end of the line. The idea of using the railroad in lieu of wires for telephoning has already been successfully tested, and the South Dakota farmers are expecting to derive great benefit from the new service, especially in the matter of information of coming storms.

Wedded by Wire.

Miss Lydia Klutte, of Oshkosh, Wis., was married to Duncan Edwards, of St. Cloud, Minn., on the 28th ult., by wire. The usual questions were asked of the groom, and his answers, made before witnesses, were returned by wire. The bride replied in person to the minister. After the ceremony was performed, the bride took the first train for the home of her husband, which was her wedding trip.

Telephones for Life-Saving Stations.

A survey has been completed for a telephone line from South Atlantic to Cape May Point, N. J., connecting all the life-saving stations. The building of this line will connect by telephone all the life-saving stations on the Atlantic coast from south of Cape Hatteras to Maine.

Latest Move in the Berliner Case.

A motion to dismiss the appeal of the United States from the judgment of the Court of Appeals of the First Circuit of Massachusetts in the Berliner Telephone patent case was submitted in the Supreme Court of the United States last week by the Bell Telephone Company. No action has yet been taken by the court.

"It is a Live Paper."

To the Editor of ELECTRICITY.

SIR: We like ELECTRICITY very much. It is a live paper. Yours truly,

FARR TELEPHONE AND CONSTRUCTION SUPPLY COMPANY.
Chicago, Ill., October 25, 1895.

Bell May Buy a Rival.

The *Tribune* of Detroit, Mich., is the authority for the statement that negotiations are pending in England for the purchase by the Bell Telephone Company of a telephone receiver owned by the Brown Loud-Speaking Telephone Company of Detroit.

Not the Western "Standard."

Some people have confused the Standard Telephone Company of New York with the Standard Telephone and Electric Company of Madison, Wis. There is no relation whatever between the two companies.

Will Be Sure to Control the News.

The cable between Havana and Santiago de Cuba, which is practically under the control of the Spanish Government, will be completed by November 10, and it is said will be of great value to Spain in the prosecution of the war in Cuba.

A stock company has been organized at Muncie, Ind., to establish an electrical call and messenger service in that city. Boxes will be placed in all localities where there is not an accessible telephone service, and at points where the interests of the public can best be served. At the central office a corps of messenger boys, provided with bicycles and a delivery wagon will be kept ready to attend to all calls day or night. Roy Coffeen will have the management of the business.

The citizens of Springfield, Ill., and the Central Union Telephone Company are having almost daily passages at arms over the pole question. The company was directed to remove certain poles, which it refused to do. A committee of citizens removed the poles with axes and the company has now instituted trespass and damage proceedings against the property owners. An injunction has been secured restraining the company from taking further steps until the case can be disposed of in the Circuit Court.

The Wisconsin Telephone Company is discovering how hard the people of Milwaukee can kick. Some time ago the company established a rule limiting the number of the calls of each subscriber to three a day or 1,000 a year and fixing a rate of two cents for each call. An indignation meeting, in which the leading attorneys and business men of the city participated, was held recently to protest against the "extortionate, unreasonable and unjust" rates of the company.

The Bell Telephone Company of St. Louis has decided to extend its system over the eastern half of St. Louis County, reaching Ferguson, Shrewsbury, Fenton, Old Orchard, Maplewood, Kirkwood and Webster Groves. The system will be operating within sixty days. Rates have not been decided upon, but will be considerably less than the present charges for suburban service.

The exchange of the Greencastle Local Telephone Company, Greencastle, Ind., has been attached by local parties who have claims against the Phœnix Telephone Company, of Indianapolis. The system was built by the Phœnix company for the Greencastle company, but owing to some hitch in the proceedings the local company has not accepted the plant.

A temporary injunction has been secured by the city council of Sheboygan, Wis., restraining the Wisconsin Telephone Company from setting additional poles until the formality of securing a franchise has been complied with.

The Board of Supervisors of Mason, Mich., has directed the Co-operative Telephone Company of that city to place its instruments in the city and county offices. The Bell instruments are to be thrown out.

John Goodnow, a prominent capitalist of Minneapolis, and a director of the Northwestern Standard Telephone Company, has been in Duluth, Minn., arranging to secure a telephone franchise.

The Baldwin Electrical and Manufacturing Company of Watertown, N. Y., is constructing the telephones to be used in the new local exchange now being erected in that place.

The Finance Committee of the Board of Works of Newark, N. J., has in preparation an ordinance granting street rights to the Newark Telephone Company.

The Board of Trade of Laramie, Wyo., is interested in the movement to establish a telegraph and telephone line between Laramie and Walden Park.

The St. Louis *Star Sayings* declares that the Bell telephone service in that city has become almost worthless. The management lays the blame on the Municipal Assembly which refuses to give the company right to construct underground metallic circuits.

W. R. Simmons of Seven Springs, N. C., contemplates building a telephone line to connect La Grange and Seven Springs.

The Painesville Telephone Company, Painesville, O., is now ready to receive bids for the construction of an exchange.

Texas Siftings is of the opinion that "the telephone complication just now is an example of 'sweet Bells jangled.'"

The Home Telephone Company has at last secured permission to enter Red Bud, Ill., with its lines.

The Wisconsin Telephone Company will extend its lines to and establish an exchange in Antigo, Wis.

The Phœnix Telephone Company of Altoona, Pa., has been granted street rights at Tyrone, Pa.

E. H. Brainard is interested in forming a new telephone company at Springfield, Ill.

New Companies Incorporated.

The North Creek, Newcomb and Long Lake Telephone Company, limited, has been incorporated to build and operate a telephone line from North Creek, by way of Olmstedville, to Minerva, thence by way of Aiden Lair to Newcomb and Long Lake, connecting North Creek, Olmstedville, Minerva, Aiden Lair, Newcomb and Long Lake, N. Y. The capital stock is $3,000, and the directors are John Anderson, jr., Dennis Moynehan, jr., and Edward Anderson of Newcomb; P. Moynehan of Glens Falls; David Hunter of Tahawus; John Donelly of Olmstedville, and T. D. Sullivan of Long Lake.

The Troy Telegraph and Stock Company—to maintain a line of telegraph or telephone from Troy to New York and the principal cities and towns of Westchester and Kings Counties, and the State of New Jersey; also to Chicago, Louisville, Lexington, and Covington, Ky.; Nashville and Memphis, Tenn.; New Orleans, St. Louis, Baltimore, Washington, and Montreal. Capital stock, $2,000. Directors: Thomas Hogan of New York City, Peter J. Turner, Patrick E. Purcell, Patrick J. Delaney, and William Miller of Troy; Eli Galaise, Jr., of Cohoes, and Charles G. Teeling of Green Island.

The Smith-Vassar Telephone Company, New York—to manufacture and operate a signal call station for telephone and telegraph purposes and to acquire and hold stock in other corporations engaged in a similar line of business. Capital stock, $1,000,000. The directors of the company are Frank S. Pusey of Council Bluffs, Iowa; Wm. L Beardsley, Frederick J. Winston, Joseph F. Barling, Augustus W. Hand, Charles W. Durland, and Edward Schmidt of New York.

A meeting of persons interested in the Berliner Gramophone was held in Philadelphia last week for the purpose of forming a company to engage in the manufacture of the 'phones. A permanent organization was effected by the election of the following officers: Thomas S. Parvin, president; W. C. Jones, vice-president and general manager; Max Biernbaum, secretary, and W. J. Armstrong, treasurer. The organization will be known as the Berliner Gramophone Company.

The articles of association of the Bridgeport Mutual Telephone Company have been filed at Bridgeport, Conn. The officers of the new company are Frederick W. Tracy, president, and William E. Bowers, secretary. The company proposes to establish a local telephone service. Membership will cost $100 and the expenses will be divided pro rata among the members. For communication with the outside world, special toll rates will be charged.

The Beaver Hill Telephone Company of Beaver Hill, N. Y.—to connect Rockland Station and Lewbeach in Sullivan County, and to connect such line with points in Sullivan, Ulster and Delaware counties, New York. Capital, $1,500. Directors: Jefferson Campbell of Roscoe, J. W. Johnston of Rockland, Jay Davidson of Beaver Hill, and others.

The Home Telephone Company, Richmond, Va. Capital stock, $200,000. Incorporators: J. N. Cullingworth, J. D. Patton, S. W. Travers and others. James Russell, Baltimore, Md., is president of the company.

The Willamette Valley Telephone Company, Portland, Ore. Capital stock, $5,000. Incorporators: John Bradley, Alexander Smeek and John W. Shafford.

The Norfolk Mutual Telephone Company has been organized at Norfolk, Conn., as a corporation without capital. George M. Coy, of Milford, is secretary.

The People's Telephone and Telegraph Company of South Dakota, with headquarters at Hot Springs, has been organized with a capital stock of $50,000.

The Oconto Telephone Company, Oconto, Wis. Capital stock, $7,500. Incorporators: Judge D. G. Classon, Dr. C. W. Stoelting and A. H. Lukenbach.

BUSINESS HINTS.

Public Buildings, Theaters, Residences, &c., Proposed or in Course of Construction.

[The following summary is prepared weekly for ELECTRICITY for the information of advertisers and readers who are dealers in apparatus and articles required in the electrical equipment of public and private buildings.]

Brooklyn, N. Y.—Walter Silsby, restaurateur, 460 Fulton st., has leased the entire corner, Fulton street and Hanover Place, which will be at once rebuilt and thoroughly furnished for restaurant purposes . August Woodbury has prepared for Mrs. Emily A. Patterson, 191 Franklin ave., plans for a five story brick improved apartment house, to be erected at the southeast corner of Harrison ave. and Cooper st . . E. Johnson & Co. has prepared for Moller Bros. & Co., South 9th st , plans for two four story stone front houses that it is proposed to erect on South 9th st.

Buffalo, N. Y.—Architect W. H. Archer has prepared plans for a store and apartment building to be erected at 397 Woodlawn ave . . . . James W. Chase will erect a four story brick block for stores and flats corner Grant and Ferguson sts., to cost $50,000.

Detroit, Mich.—Gilbert Wilkes, the consulting electrical engineer, has advised the Board of Education that it will be more economical to have a separate lighting plant for the new high school building than to light the building from the city's lighting plant.

Doylestown, Pa.—Architects Baker & Dallert, of Philadelphia, are now engaged in drawing plans for a handsome new building which the First National Bank of Doylestown intends erecting.

Kansas City, Mo.—The Karnival Krewe committee on lighting propose to expend $15,000 for lighting the city during the carnival week; the committee on street illumination consists of John Sullivan, W. W. Cowan and George P. Gloss.

Lewiston, N. Y.—Messrs. Carrell & Fleming, of Lewiston, have purchased the Piper mansion from Dr. T. W. Bartlett, of Buffalo, and will at once convert the structure into a first-class hotel with all modern improvements.

Miami, Fla.—It is rumored that H. M. Flagler will erect here a 1,500 room hotel.

New Britain, Conn.—A movement is likely to be started soon by a number of our prominent citizens towards the erection of a new city and town building.

New York City.—Edward Kilpatrick, 50 West 67th st., will erect a ten story hotel at 94th st. and Central Park West, to cost $175,000; Architect Frederick Jacobson.... Walker & Lawson have purchased a plot of about four lots on southeast corner of Riverside Drive and 84th st., with the purpose of erecting high class dwellings thereon... Richard S. Barnes, of Washington, Conn, will build a five story brick dwelling north side of 75th st., east of Riverside Drive, to cost $60,000 ... Frederick Brandt, 538 East 84th st., will erect 2 five story flats south side of 105th st., west of Park ave.; Architect John Brandt Andrew J. Kerwin & Son, 316 West 88th st., will build 2 five story flats on north side of 99th st., east of Amsterdam ave.; Architects A. B. Ogden & Son, 1031 Madison ave.... Architects Schneider & Herter, 48 Bible House, have prepared plans for a six story store and flat to be erected at southwest corner of Allen and Rivington sts ... Abraham and Harris Cohen, 232 Henry st., will erect a five story store and flat at 138 East Broadway .. James Livingston has purchased four lots, 420–426 West 20th st., and will improve the property at once by the erection of 3 five story flats.

Peoria, Ill.—The State Board of Commissioners have decided to locate the Asylum for the Incurable Insane at Peoria; the asylum will be the largest of the State institutions and will accommodate 5,000 people; the estimated cost is $2,000,000; work will be begun on the new buildings this winter.

Philadelphia, Pa.—Chester H. Kirk is preparing plans for a handsome residence to be erected for Wm. F. Harrity on lot recently purchased by him at Overbrook; bids will soon be asked for.

Stafford Springs, Conn.—A syndicate of local business men have caused work to be started on a hotel building to be called the Spring House, which is to be ready for occupancy about January 1st.

INCORPORATIONS.

The Clear Lake Electric Power Company, Lakeport, Cal.—to construct and operate irrigation works, construct electric power producing works and manufacture electricity. Capital stock, $2,000,000. Promoters: E. P. Clendenin, D. C. Rumsey, Lakeport; J. K. Fraser, Kelseyville, Cal.; C. E. Moore, San Francisco; Richard Wylie, Napa, Cal.

The Key West Electric Light and Power Company, Key West, Fla.—to operate and maintain electric lights and power for public use. Capital stock, $25,000. Promoters: Chas. Curry, M. L. Kellings, M. W. Curry, Jos. Y. Porter, Key West.

The Barrie and Allendale Electric Street Railway Company, Barrie, Ont., Can.—to construct and operate an electric railway in Barrie and suburbs. Promoters: J. H. McKeggie, J. Vair, G. Reedy, S. J. Sanford and J. Dickinson, all of Barrie.

The Monroe City Electric Light Company, Monroe, Mo. Capital stock, $10,000. Promoters: Wm. Wood, E. P. Nelson and W. T. Ragland.

The Logan County Electric Light Company, at Lincoln, Ind. Capital stock, $10,000. Incorporators: John W. Lutz Charles C. Reed, John St. Cerny, T. A. Reynolds, Adam Denger, D. H. Harts, R. H. Gains and John A. Lutz.

The Schuylkill Traction Company has filed its charter at Doylestown, Pa. The company proposes to build and operate trolley roads in that part of Pennsylvania, and in adjoining States the waters of which drain into the Delaware and Schuylkill rivers. Capital stock, $50,000. Incorporators: Wm. Jenks Fell, Francis Fennimore, Marshall S. Lynch, Robert C. Fulton and Samuel Hamilton.

The Essington and Chester Railroad Company—to build an electric line from Essington to Chester, Pa., a distance of four miles. Capital stock, $50,000. Directors: William Simpson, Jr., Joseph B. Townsend, Jr., Overbrook, Pa.; Charles C. Townsend, Philadelphia; William H. Badger, Jr., Wayne, Penn.

The Hafemeister Electric and Machine Company, Cleveland, O. Capital stock, $5,000.

The Hollister Company, Hollister, Cal.—to furnish water for domestic use, irrigation and power, and to generate electricity for light and heat. Capital stock, $100,000. Promoters: T. S. Hawkins, N. C. Briggs, John T. Lowe, E. A. Crepin, A. S. Jones, Hollister.

The Akron and Cuyahoga Falls Rapid Transit Company has increased its capital stock from $300,000 to $600,000.

The Philadelphia Electric Storage Renting Company, with a capital stock of $300,000, of which $1,000 has been paid in, has filed articles of incorporation with the County Clerk at Camden, N. J.

The Buffalo Traction Company, Buffalo, N. Y.—to construct a street surface railroad sixty-six miles long, in, through and to points in the neighborhood of Buffalo. Capital stock, $3,000,000. Directors: E. G. S. Miller, Joseph B. Mayer, Leonard B. Crocker, Washington Bullard and Herbert P. Bissell, of Buffalo; Tom L. Johnson, of Cleveland, Ohio; Richard Ladenburg, John K. Page and Louis Kahn, of New York.

The Marysville Electric Light and Water Company, Marysville, Mont.—to manufacture and generate electricity and deal in same, etc. Capital stock, $50,000. Promoters: Geo. Berg, Chas. C. Wenstrom, John Edgerton.

The Smith-Vassar Telephone Company, New York City—to make and sell electrical devices, etc. Capital stock, $1,000,000. Promoters: W. L. Beardsley, F. T. Winston, J. T. Darling, A. N. Hand, New York City.

Card's Improved Fuse Box for Street Railways.

In street railway service the fuse box is a necessary part of each car equipment and should receive the careful attention of every street railway company. The success of any system depends largely on the completeness of minor parts and the readiness with which they perform their share of the work.

The accompanying cuts show Card's Improved Fuse Box for street railways, manufactured by the Card Electric Company, Mansfield, O. Fig. 1 shows the slate box without metal case and is well adapted for use on cars when placed under the seat or in some other protected place. It is made up with a slate bottom and sides and has brass binding blocks at each end for securing the connecting wires. At one end is a small spool, on which is wound a length of the fuse wire selected. The wire passes from the spool under a clamping piece on the binding block, through a slot in the slate partition and under another clamp on the opposite binding block, completing the circuit. Fig. 2 shows the slate box in a metal case, for use on the outside of cars. The lid closes tightly and the box has a projection along the top, making it water and snow proof. A folded piece of asbestos slips inside the box along the sides, over the fuse, insulating the lid. Fig. 3 shows the box with the front open, exposing the fuse. The spring on the outside of the lid acts to hold it either closed or open.

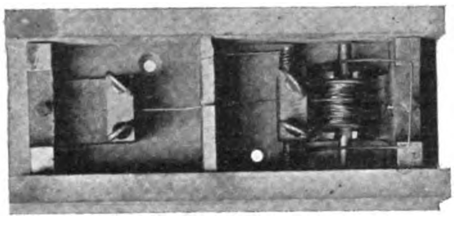

FIG. 1.

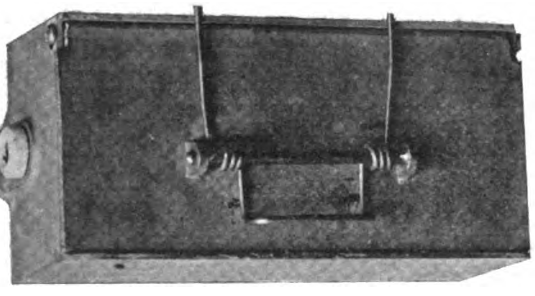

FIG. 2.

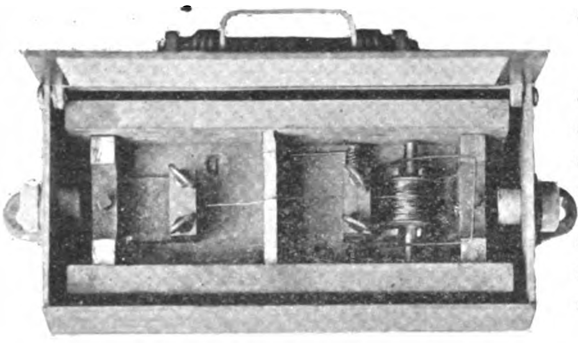

FIG. 3.

When a fuse blows, all that is necessary to do is loosen the thumb screws, pull through more wire and clamp it down. No hunting for wire never found and no time lost. Each spool will hold 35 feet of No. 21 copper wire, enough for 100 50-ampere fuses. When the wire is used up the empty spool can be taken out and a full one put in without loss of time.

As the proper size of wire to use depends largely on the grades, service and the motors, it should be determined by the superintendent and then adhered to. This method will save burn-outs, time and money. It is not safe to permit motormen or conductors to select their own fuse wire, since the temptation is great to put in a large one and save themselves the trouble of frequent renewals.

The value of this improved fuse box can be better appreciated by street railway managers by ordering one from the Card Company for trial. The price complete is very low.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 29, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

548,704. Trolley-Wheel. Ferdinand J. Feldt, Peoria, Ill., assignor of one-half to Arthur Hoklas, same place. Filed April 20, 1895.

548,786. Underground Electric Railway. Henry B. Nichols and Frederick H. Lincoln, Philadelphia, Pa. Filed March 11, 1895.

548,976. Closed-Conduit Electric Railway. Michael F. Flynn, Stamford, Conn. Filed Nov. 27, 1894.

548,997. Electric-Motor-Car Trolley. James M. Kennedy, Hollidaysburg, Pa., assignor of three-fourths to Thomas F. Johnston, same place, and William F. Gable and Galen Hemperly, Altoona, Pa. Filed May 31, 1895.

549,091. Trolley for Electric Railways. Jacob Hess, Scranton, Pa. Filed May 13, 1895.

ELECTRIC LIGHTS AND APPLIANCES.

548,682. Electric-Arc Lamp. Malone Wheless, Washington, D. C. Filed May 2, 1895.

548,683. Electric-Arc Lamp. Malone Wheless, Washington, D. C. Filed June 8, 1895.

548,899. Adjustable Incandescent-Lamp Holder. Edward Wade, Lawrence, Mass. Filed April 1, 1895.

549,074. Electric-Arc Lamp. Regina Niewerth and Hermann Niewerth, Berlin, Germany, assignors to Niewerth & Co., same place. Filed April 25, 1895.

549,075. Electric-Arc Lamp. Regina Niewerth and Hermann Niewerth, Berlin, Germany, assignors to Niewerth & Co., same place. Filed April 30, 1895.

549,083. Electric-Arc Lamp. Malone Wheless, Washington, D. C., assignor to Edward W. Creecy. Filed March 6, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

548,684. Dynamo-Electric Machine. Norman Whichello, Chicago, Ill. Filed July 18, 1895.

548,709. Polyphase Alternating-Current Motor. Fred S. Hunting, Fort Wayne, Ind. Filed March 14, 1893.

548,789. Distribution System for Alternating Currents. Alva L. Searles, Brooklyn, N. Y. Filed April 18, 1895.

548,829. Device for Regulating Current Admitted to Electric Motors. Frank E. Herdman, Winnetka, Ill. Filed March 22, 1895.

548,830. Automatically Controlling Electric Motors. Frank E. Herdman, Winnetka, Ill. Filed June 29, 1895.

548,930. Turbine Electric Generator. Charles E. Sargent, Chicago, Ill. Filed Sept. 19, 1894.

549,061. Indirect Control of Motors. Gano S. Dunn, New York, N. Y., assignor to the Crocker-Wheeler Electric Company, of New Jersey. Filed Aug. 12, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

548,623. Sound-Record and Method of Making Same. Emile Berliner, Washington, D. C. Filed March 18, 1893.

548,729. Telautograph. George S. Tiffany, Highland Park, Ill., assignor to the Gray National Telautograph Company, Richmond, Va. Filed March 16, 1894. Renewed April 23, 1895.

548,748. Microphone. Lars M. Ericsson, Stockholm, Sweden. Filed July 6, 1895.

548,897. Telephone-Switch. John E. Thomas, Cleveland Ohio, assignor to the Union Electric Company, same place. Filed April 17, 1895.

548,969. Telegraph-Instrument. Orville A. Dickinson, Arverne, N. Y. Filed July 13, 1895.

549,053. Telegraph-Pole. Albert A. Blow, Denver, Colo Filed Jan. 26, 1895.

BATTERIES.

548,730. Dry Battery. John T. Todd, Tuscola, Ill. Filed Feb. 6, 1895.

549,023. Secondary-Battery Plate and Method of Preparing It. John J. Rooney, Brooklyn, N. Y. Filed Apr. 1, 1895.

549,079. Secondary-Battery Grid and Plate and Method of Preparing Grids. John J. Rooney, Brooklyn, N. Y. Filed July 22, 1895.

MISCELLANEOUS.

548,669. Insulator-Pin. Charles W. Stephens, Camden, N. J. Filed Feb. 9, 1895.

548,700. Electrical Recording Apparatus. Albert C. Crehore, Hanover, N. H. Filed April 8, 1895.

548,701. Indicator for Electric Currents. Albert C. Crehore, Hanover, N. H. Filed May 25, 1895.

548,743. Non-Conducting Covering and Process of Constructing Same. Philip Carey, Cincinnati, Ohio. Filed March 1, 1894.

548,744. Electric Switch. John C. Cassidy, East Orange, N. J. Filed July 19, 1895.

548,755. Electric Meter. Ralph O. Hood, Danvers, Mass. Filed March 9, 1895.

548,777. Electrode for Applying Electric Currents. Edwin F. Davis, West Caton, assignor of one-half to Quincy W. Wellington, Corning, N. Y. Filed June 10, 1895.

548,819. Electric Switch. Hiram Ross, Providence, R. I. Filed July 17, 1895.

548,867. Rheostat Element. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Feb. 28, 1894.

548,904. Automatic Time Cut-Out. Francis B. Badt, Chicago, Ill. Filed Sept. 24, 1894.

548,924. Electric Train-Signal. Myron W. Parrish, Detroit, Mich., assignor of three-tenths to Stephen K. Stanton, J. H. Carstens, and Frederick T. Sibley, same place. Filed Dec. 24, 1894.

548,949. Safety and Limit Switch for Electric Motors. Geo. F. Card, Mansfield, Ohio. Filed Aug. 21, 1895.

548,952. Electric Brake. Frank E. Case, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed June 29, 1894.

548,968. Automatic Circuit-Breaker Alarm. John H. Devine, Johnstown, Pa. Filed Nov. 13, 1894.

EDITORIAL NOTES.

Promoters or Pirates? At the first annual meeting of the Ohio Electric Light Association there was considerable informal discussion of one of the evil features of the policy which has been practised by some of the leading electrical manufacturing companies since the early eighties. The following resolutions passed:

> Whereas, Certain manufacturers of electrical apparatus have in the past, and are at this time, attempting to secure franchises for the installation of electric lighting plants in certain cities of this State; and
>
> Whereas, These franchises are not sought for the purpose of making a legitimate investment, inasmuch as the demand for electric service in these towns is not sufficient to support an additional company, but is rather for the purpose of compelling the existing companies to become customers of these manufacturing companies;
>
> Resolved, That this association now puts itself on record as condemning such business methods as being neither more nor less than blackmail, and that such methods justify the association in requesting each of its members to refuse to purchase of such companies any apparatus whatsoever if they thus continue their piratical attacks upon the invested capital which this association represents.

ELECTRICITY has been perhaps the only paper in the field with courage enough to handle the manufacturers who have been guilty of this species of blackmail without gloves. Its application has been the direct cause of an endless amount of trouble, of the loss of large amounts of honestly invested capital, the enrichment of a few of the pirates and the discrediting of this class of investments.

The Ohio association has done well to face the problem so early in its life, and we trust the National Electric Light Association at the next annual meeting may take even a more radical position. It should have done so long ago.

The kind of business morality which has been exemplified in the application of this method of blackmail is well illustrated by the following, which appeared in ELECTRICITY of January 2:

At the time of the G. E. consolidation the Denver Consolidated Company was buying everything from the G. E. Company, its purchases amounting to several thousand dollars monthly. The company was prosperous and had declined several overtures to mix itself up in financial deals with the Eastern people. Soon after coming to New York, Mr. Coffin called one of his agents into his private office and said to him:

> "You are pretty well acquainted at Denver, and we want some special work done there. You remember a few years ago we decided to start a small opposition company there, and they finally bought us out. We made a handsome profit. Now the Denver Consolidated Company has a capital of $1,000,000 and we must have some of it; it is good stock and pays 10 per cent. annually. We think you ought to go to your friends there and organize a new company. The Consolidated people would probably prefer not to be hostile to us and might give us about $250,000 of that stock. You see, I know all of Mr. Rawlins's (president of the Denver Company) financial friends in the East, and might have some influence on them in future deals of his if he chose to be unreasonable. Now, you go out to Denver and scorch them at that end and I will burn them up at this end."

* * *

Why Not Standard Prices? The complaint is commonly heard that there exists no standard of prices or discounts for the staple articles of the electrical supply trade. The complaint is well founded, as every well-posted buyer and dealer knows. Just why the electrical supply trade has been so long conducted upon the principle of "business at any price" is not susceptible of explanation, but certain it is that the continuance of variable and various prices and discounts has not added to the volume of trade; it has not increased profits, nor has it tended to inspire mutual confidence between buyer and seller.

The electrical supply business is no longer an "infant industry." It is no longer in the hands of people who know comparatively little about it—differing in this respect from a period in its history which is not so remote as to have been entirely forgotten. Nearly or quite all of the goods which now go to make up the stock of a well-equipped establishment have practically become standardized. A 3-inch bell, made by reliable manufacturers, is much the same everywhere. So also are insulated wires, battery cells, lamp sockets and a hundred other articles constantly required by electrical contractors; but the prices differ as widely as do the temperaments of the individual dealers. A may sell a 3-inch bell for 30 cents, B for 28 and D for 27. D may sell other articles at higher prices than A or B, and B may have some goods for which he may ask higher prices than A. And so on ad infinitum.

There is just as much need for standard prices and standard discounts in the electrical supply trade as there is in the hardware or any other established trade. A building contractor knows to a certainty that he can buy nails as cheaply from Jones & Company as he can from Smith & Company, but an electrical contractor is confronted with a multiplicity of prices and discounts on all the various articles he needs to complete a contract. Being the largest buyers, contractors naturally feel the need of standard prices the most. Oftentimes it happens that a contractor is perplexed to know why his bid on a contract exceeds that of a competitor. He has secured from his supply dealer what he believes, or has reason to believe, are the lowest prices. He has figured on the usual per cent of profit. His competitor, paying the same for labor. figures the same way and obtains the contract because he had secured lower prices on perhaps one class of goods used in the work. It is not in this particular that the contractors have suffered the most. It has been, and still is, the practice of some dealers to sell goods in dozen lots to amateur electricians and small contractors at almost as low prices as they do to the buyers of hundred or thousand lots.

Happily this rule of business is becoming obsolete, but there are many of the reputable contracting houses in the smaller cities and larger towns which have suffered the loss of much trade on account of it. More than that, the whole electrical industry has suffered. An amateur with perhaps a $25.00 stock of goods, and who estimates his profit on a contract upon the basis of obtaining fair wages for the time occupied with the work, has always been able to underbid all competitors, unless they are of his own class. In all such cases the customer sooner or later discovers that he has secured just what he paid for, and no more. He finds that cheap electrical apparatus, installed by a cheap contractor, operates for a time, then does not. He becomes disgusted with the much vaunted superiority and reliability of electrical appliances and throws out the bargain-counter material. A neighbor hears of it and postpones, if not abandons, the purchase of a contemplated installation. As a consequence the dealer and contractor both lose, but the responsibility rests with the dealer who sells to large and small buyers at the same price.

The supply dealers have long felt the need of an agreement as to prices and discounts, but no systematic effort has ever been made to bring it about. The movement inaugurated in Philadelphia some time ago, looking to the formation of a local association, may, and it is hoped it will, lead to good results.

The leading dealers in New York have already had several informal meetings at which the question has been discussed. Thus far no definite action has been taken in either city, but the indications are favorable to a mutual understanding and agreement upon the all-important matter of prices, and possibly the organization of associations on the lines of those of kindred commercial bodies. The sooner it is brought about the better it will be for the whole industry.

* * *

John Jacob Astor and The Spiro-Vortex.

Mrs. Bloomfield Moore, scientist, physicist, Keelyist, magazine writer and pamphleteer, is reported to have sold to John Jacob Astor all her right, title and interest in the Keely motor, the Keely Motor Company and the inventions of John W. Keely, whose alleged discoveries in physics now threaten, it is said, to more nearly eclipse the achievements of electricity than ever before. Mr. Astor neither affirms nor denies the truthfulness of the report. It is well known that he is interested in scientific pursuits, and it is also known that he was but recently a visitor to Keely's laboratory. It was upon the occasion of this visit, no doubt, that Mr. Astor was convinced Keely "has grasped the greatest hidden secret—the power of the will—and now offers the key of the door that leads from the realm of matter to the realm of mind to all who are ready to pursue their researches in the new fields." Probably at the same time it was made plain to him that Keely's "latest discovery—that of the spiro-vortex action of currents of force—is so overwhelming in its simplicity of demonstration that it needs but to be witnessed to convince physicists that vibratory physics will place science on an height never before attained."

Some time ago Keely made the rather frank admission that the force he discovered twenty-two years ago, and the inventions connected with it, are "practically valueless," because he "was unable to harness or control the force for commercial purposes by any of the devices constructed for its use." This does not signify that Keely is either disheartened or dismayed, but merely prefaces his plan "for the organization of an entirely new company, capitalized in such a manner as to enable me to prosecute experiments for the further applications of the new force to my heart's content." Part of the capital of the new company is to be set aside for the cancellation of the "speculative obligations" incurred by Keely when he was "yet groping after light." Another portion is to be used as working capital, and the balance, the inventor modestly announces, he "will retain for my own use."

With the working capital of the new company, the inventor asserts, he will be able "to produce a thoroughly practical commercial engine" for the use of his newly discovered force on all railroads. To the New York *Herald*, which publication divides with the *New Science Review* the honors if not emoluments of press agent for the Keely Motor Company, we are indebted for the following graphic description of the successor of the locomotive and street car motor:

> The most wonderful use to be made of this new force is in the push engine, or machine intended to propel street cars or vehicles of any kind on earth or in water. This is described as being a cylinder, 18 x 8 inches approximately, boxed up in portable form. This box is to be fastened to the front platform of the vehicle, and, without any gearing or wire connection or connection of any kind between the box and the wheels, the energy generated in the box is to turn the wheels and push the vehicle along. Some time next year it is expected that the people will be able to get light, heat and power in their homes and factories at trifling cost.

In such a company, organized for such a purpose, and capitalized after the manner proposed by Keely, John Jacob Astor will be a useful man to have as director. So also would Rothschild, or even Barney Barnato.

The electrical, scientific and commercial worlds await the confirmation of the above rumor with scarcely less interest than they await the appearance of the spiro-vortex "push engine," or the "cylinder, 18 x 8 inches approximately, boxed up in portable form."

Under the Searchlight.

Views and Opinions on Timely Topics.

THE EIGHTH DUKE OF MARLBOROUGH.

Important Services Rendered in Behalf of the Electrical Trades.

The marriage of the ninth Duke of Marlborough to Miss Vanderbilt recalls the services rendered by his father in behalf of various lines of electrical development in England.

When his magnificent ancestral estate of Blenheim had become impoverished, and his banking account seriously depleted, he resolved to visit the United States in quest of knowledge, and incidentally a rich wife too if one could be found. The Duke was successful in every respect and married the millionaire widow, Mrs. Hamersley.

He was particularly impressed with the marvelous achievements of our electrical inventors, and studied closely what was being done in that particular department of our American business life. On his return to England he applied well and usefully the knowledge thus gained.

Before stating just how he availed himself of his American experience and knowledge, it will be well to enumerate a few facts that may be of interest to our readers because of their bearing on electrical development throughout Great Britain.

In 1880 Edison's announcements created a great scare throughout England as well as elsewhere. The gas industry was very prosperous, gas stocks were regarded as among the safest and most profitable of securities. Many members of the English Parliament—both Lords and Commoners—held large blocks of gas stock which were paying good dividends. Edison's startling claims portended ruin, and the "deadly electric fluid" must be switched off or grounded. If it found favor with the English people, down would tumble the values of gas stocks and substantial dividends would become things of the past. Such a condition of things could not be tolerated, and soon every attempt at introducing electric lighting into England on a commercial scale was so harassed and threatened by absurd and unreasonable conditions, so many obstructive enactments became law for the benefit of gas stock holders, that in time the promoters of electrical enterprises became weary of opposition and practically abandoned the business.

Thus matters remained for something like ten years, very little progress being made in the adoption of electricity for either lighting or power purposes. No sooner had the late Duke returned from America than he took his seat in the House of Lords. He had now ample means at his command and a fund of practical knowledge and experience to aid him in wisely investing his newly acquired wealth. He talked about the marvelous achievements of electrical science in the United States, and won the attention of wealthy friends and acquaintances. He set forth the advantages of electrical illumination for London and the provincial towns and cities of England. He became an active promoter of an electric light company. His enthusiasm became contagious. Englishmen were convinced that they were behind the times. As the Board of Trade began to be again and again appealed to for what we in America call franchises or charters, by newly organized companies desirous of going into the electrical business, that exalted and conservative body found that it was imperative that they should grant concessions; and they did, the speedy result being that the gas companies no longer enjoyed monopolies, and such an impetus was thereby given to electrical development that it has even up to the present time lost none of its momentum.

"Honor to whom honor is due" is a trite saying, yet the writer cannot but think that the electrical fraternity in England, as well as many others over there who are interested in the advantages and benefits accruing from the increasing use of electricity, will willingly concede the full meed of praise and credit due the memory of one who, though a blue-blooded English aristocrat, did much in his latter years for the commercial supremacy of his native land.

If the youthful scion of the noble house of Churchill, who is about to return to the magnificent palace of Blenheim, makes as good use of his wife's substantial dowry as did his late father, then we as Americans shall have slight cause for criticism or complaint.

* * *

The Burton Smelting Process.

(From the Pacific Electrician.)

Mr. George D. Burton, who recently astonished the local mining men on this coast by performing some variations of the electrical forge experiments, and who formed a company here, is now in the East organizing corporations right and left.

Like the tin-type man, he will finish your corporation while you wait.

Recently he got his picture published in the *Electrical Engineer*, with an article telling of his wonderful discoveries.

An engineer who looked into Mr. Burton's claims when he was in San Francisco reported to us that he had no patents of any value, and that any attempt to operate his electric forge for smelting on a large scale would be absurd.

* * *

Electric Sand Man Redivivus.

The Elmira *Advertiser* says that a company has been organized which may establish a factory in that place to manufacture a new electric bicycle and carriage lamp which "is a decided novelty," as the following description certainly shows:

"The new lamp is composed of a secret composition which is similar to asbestos, and is pressed out in a hydraulic press with a force of about 200 tons. It is indestructible and cannot break. A small incandescent lamp is placed in the reflector and is connected with two zincs and a small cell battery in the interior of the lamp. The battery is charged with the contents of a small box of sand which is chemically prepared and is dissolved in water. The lamp is then ready for use. No switches or other mechanism is used on the lamp, the light being shut off by simply inverting the lamp, which carries the chemical solution away from the zincs in the battery.

"The lamp has proved a decided success and will burn about four hours continuously without recharging. The light is very strong and white, and small objects are readily distinguished fifty feet ahead the dark. The chemical sand can be obtained at a wholesale rate of about one and one-half cents per box, which makes the cost for operating it nominal."

* * *

The Dead Game Sport.

(From the Pacific Electrician).

The *Electrical Engineer*, under the heading "Engineers as International Yachtsmen," states that Mr. C. J. Field, the electrical engineer, is the owner of the "Ethelwynn," the yacht that won the recent international race for half raters. Mr. Field is also the man who got frightened at the waves and threw up the race, as well as his dinner. He is hardly a person to take very much pride in.

* * *

The Svengali Buncophone Company.

At the last monthly meeting of the Board of Directors of the Svengali Buncophone Company, A. F. Akir, secretary and treasurer, presented the following statement:

Number State companies organized	48
Capital stock of same	$480,000,000
Number State sub-companies organized	480
Capital stock of same	$960,000,000
Number Telephone rights sold	998,789
Number Telephones installed (in exhibition room, general offices)	2

It was voted to increase the stock bonus to local organizers to $250,000 each, and to increase the commission for sale of rights to 90 per cent., to be paid in stock.

The name of Barney Barnato was added to the directorate of the parent company. The secretary was directed to notify this gentleman of his election and to request him to name a good man to sell telephone rights in the Kaffir country.

* * *

THE Nye who was frescoed with stale eggs at Paterson, N. J., a few nights ago, was not the Allen T. Nye of Standard Telephone fame.

* * *

THE letter printed below was referred to in ELECTRICITY last week. The circular mentioned is the one which has become familiar, designed to awaken enthusiasm among "the boys who are in the real pot," and providing for the greasing of Common Councils:

ALBANY, N. Y., Oct. 25, 1895.

EDITOR ELECTRICAL DEP'T N. Y. HERALD,
New York City.

DEAR SIR: To correct statements made by Mr. Clarkson as stated in clipping from *Herald* of Monday last, I send you herewith circular which came direct from the Standard Telephone Company's office on July 27th last. No paper can expose the inside work of this promotion company as well as the *Herald*, and it should be done to prevent innocent parties being placed in false colors to the public. Ask them what telephone patents they own or control. I am told the Phœnix Interior Telephone Company, 131 Liberty street, has made what few instruments the Standard Company have put out. They may be able to give you some information.

Yours truly, W. V. D.

* * *

IT is not true that the Pennsylvania Light, Heat and Power Company has leased the Philadelphia Edison Company or absorbed it. The plan is proposed and awaits action by the stockholders at the next annual meeting. ELECTRICITY'S guess is hereby on record that a majority of the stockholders will refuse to tie up to a shadow.

* * *

THE *Railway Age* exhibits the saving grace of common sense when it says: "But it is well to remember that enthusiastic claims made for new appliances are not always sustained by experience, and that the canal trolley is as yet little more than a theory. After it has been put into practical service under varying conditions over a long line, in place of the 1¼-mile course on which the test was made, there will be a basis for determining the cost of operation and maintenance."

'Twas Ever Thus.

As fast as the Electric Storage Battery Company absorbs one company, four or five others are formed with capital ranging from $1,000,000 to $10,000,000. 'Twas ever thus with Trusts. It is a fair proposition that when a Trust succeeds in making, say 50 per cent. profit, sandbaggers step in and take 30 or 40 per cent. of it, leaving just about the old-fashioned manufacturer's profit. Of course the Electric Storage Battery Company has as yet made no money, but they have sold stock and have a well-filled treasury which answers the same purpose; and there are a great many men in this field who have learned to strike while the iron is hot, or, as it were, to pull the leg before it is broken. By the way, a little of the water has been squeezed out of Electric Storage, which has dropped from 75 to 30 recently. If Philadelphia investors had read ELECTRICITY carefully they could have saved themselves a few millions of dollars. We wonder if it has ever occurred to these people to investigate what the capitalization of $13,500,000 means. It does not represent property, business or achievement. The best definition which we can give is that it represents a possible, though long and vainly sought, discovery.

* * *

IN a recent interview Mr. Charles R. Huntley is quoted as follows:

"I have no doubt whatever that the problem of transmitting the power from Niagara to Buffalo without serious loss will be successfully met. It certainly can be no more difficult to transmit the electrical current in Western New York than in other parts of the world, and it is a matter of general knowledge among electricians that power has been successfully transmitted by electricity in many cases over as great distances as from Niagara here. It is done in Switzerland, in Germany and in several places in the West. The heavy transmission of power for the Telluride mines of Idaho are famous. I believe that the time is not far distant when the manufacturers of Buffalo will use all the Niagara power they can get."

This is what Mr. Huntley says when his hat is full of holes. But what does he really think?

* * *

A GREAT deal of rubbish is floating about in regard to the late Eugene Field. Among other things there has been printed the statement that he spent an inheritance of $70,000 in one year in the city of Paris. Mr. Field never inherited $70,000 and never spent that amount in one year. What he did spend abroad was not spent without judgment either, as any visitor to his home could testify. Money spent for rare books cannot be wasted, and Mr. Field's "When I was Broke in London," written not long after his return, shows pretty clearly the chief subject on his mind at that time.

* * *

MR. DE LANCEY NICOLL, who was District Attorney of New York County when the publisher of ELECTRICITY was indicted for libel on the complaint of Mr. C. A. Coffin, said at a recent dinner party in this city: "The only thing in my career as District Attorney that I regret is that the publisher of ELECTRICITY was indicted during my term. However, I was in Chicago at the time, and when I returned I had the pleasure of telling some of the G. E. officials what I thought of the trick then."

* * *

MR. WALTER K. FREEMAN bobs up in San Francisco with a charge of attempted fraud against the Westinghouse Company's attorney, and it is encouraging to know that Warren P. Freeman denies every charge made. Mr. Walter K. Freeman ought to be squelched. His career of perjury and blackmail, not to mention other crimes, has been too long extended.

* * *

LOUIS C. DIEKMANN, of St. Louis, in a recent interview on the telephone situation, is reported by the St. Louis *Chronicle* to have said: "Don't ask me about this so-called Standard Telephone Company. I think it must be what Ingalls calls the Monroe Doctrine—'a vague sentiment.'"

The Explanation.

(From the Boston News Bureau.)

The General Electric people expect that the company will show for the present fiscal year about 3 per cent. earned upon the common capital shares. The cash on hand is as it has been for some time past about $500,000.

As the company is now doing business upon a cash basis, the only explanation which is given as to why the company's cash does not increase faster is that the expansion of business has required an increased investment in tools, machinery and raw materials.

* * *

THE United Electric Securities Company has made a renewed attack upon Messrs. McDonald and Hart and the Louisiana Electric Light Company, and again asks for a receiver. If persistence is proof of right, the Securities Company ought to win.

* * *

It Is.

(From the Atlanta Journal).

ELECTRICITY is the power of the world.

* * *

"It is not likely that enough power will ever be obtained from Niagara, over and above that which will be taken by nearby consumers, to operate boats along the entire length of the canal. But the charter of the Cataract General Electric Company gives it permission to use the power of any cataract or waterfall."—*New York Press.*

WHEN the power of Niagara is exhausted, the cableway can be supplied from the falls of the Yellowstone or the Zambesi.

* * *

General Electric.

(From the Wall Street News.)

A Boston newspaper says that the greater part of the decline in General Electric this week came on the return of Pennsylvania Railroad officials and New England capitalists from a view of the Westinghouse works in Pittsburg. It is said on the best authority that the negotiations between the General Electric and the Westinghouse for exchange of patent rights, which promised harmony in the electrical field, were broken off in an hour after they were ready for signature. The reason for breaking these negotiations never has been made public, but has been making trouble in the General Electric camp ever since.

* * *

AT the recent election in this State an appropriation of $9,000,000 was authorized for the improvement of the canals, and $4,000,000 will be ready to draw on in 90 days. State Engineer Adams has already prepared elaborate plans, and we fail to see any reference therein to Mr. Hawley's aerial towing scheme.

* * *

And Clean Hands Too.

(Miss Frances Willard, Pres. W. C. T. U.)

Steam and ELECTRICITY, machinery and invention, have put level heads at a premium.

* * *

WE are glad to know that Mr. Charles L. Ackerman, having fully recovered his health, has begun active work in the San Francisco office of the Westinghouse Company. Mr. Ackerman's training on ELECTRICITY fits him to occupy any position with credit to himself and profit to his employer.

Among the technical novelties introduced in Germany the new electric suspension railroad between Leipsic and Halle deserves mention. The system is a recent invention of Eugene Langen of Cologne, and its distinctive feature is the suspension of the cars. The only place where this new system has so far been tested for a short time is on a special line between Cologne and Deutz, a suburb, but there it has been found eminently successful. By the new system the running time between Leipsic and Halle, 22 miles, is to be reduced from 35 minutes, as at present, to 15 or 20 minutes. The Berlin municipal authorities are very anxious to see this new line in operation, as in the event of all the promises made being carried out, it is the intention to build several electric suspension roads for intramural traffic at Berlin.

The Standard Telephone Co.

Its Long "Roll of Honor."

The following list of eminent names is a copy of a document issued by the Standard Telephone Company of New York, for the purpose of inspiring confidence in its scheme for the sale of stock and rights :

THE STANDARD TELEPHONE COMPANY.

BOARD OF DIRECTORS OF PARENT COMPANY.

Capital, $10,000,000.

THURLOW WEED BARNES, Capitalist; President Standard Telephone Company, 253 Broadway, New York.

JOHN A. BRILL, President of J. G. Brill Company, Car Builders, Philadelphia, Pa.

CARL F. BOKER, senior partner Hardware, Steel and Iron House of H. Boker & Co., New York.

JOHN W. CANDLER, Merchant; ex-President Boston Board of Trade; R. R. President; ex-Member Congress, etc., Boston, Mass.

GEORGE CROCKER, Capitalist, San Francisco and New York.

JOHN P. JONES, United States Senator, Nevada.

HENRY MERZ, President Heller-Merz Co., Manufacturers of Colors; President Color Manufacturers and Druggists' Association, etc., New York.

ALLEN T. NYE, General Manager Standard Telephone Company, formerly General Manager Overland Telephone Co., New York.

MANNING C. PALMER, President Syracuse National Bank, Electric Light Co., etc., Syracuse, N. Y.

FELIX RAKEMANN, of the firm of Balch & Rakemann, Boston, Mass.

JOHN E. SEARLES, Secretary and Treasurer of the American Sugar Ref. Co., New York.

CHARLES T. STRAUSS, Charles T. Strauss & Brother, 468 Broadway, New York, and St. Gall, Switzerland.

LOUIS WINDMUELLER, senior partner L. Windmueller & Roelker, prominent member of the Chamber of Commerce, etc., New York.

NEW YORK STANDARD TELEPHONE COMPANY.

BOARD OF DIRECTORS.

JOHN E. SEARLES (President), President R. R. Co.; Director and Treasurer American Sugar Refining Co ; President and Director of many other corporations, manufacturing companies, etc., New York City.

WINTHROP MURRAY TUTTLE, Vice-President, Secretary and Treasurer B. C. P. R. R. Co., and President A. K. W. Co. and various other corporations, New York City.

CHARLES T. ARMSTRONG, Sugar Importer; Ship Owner; Capitalist, New York City.

LOWELL M. PALMER, President Brooklyn Cooperage Co., Manufacturers Barrels for Sugar Trust, Brooklyn, N. Y.

WM. DICK, Capitalist; Director American Sugar Refining Co.; Dick, Meyer & Co., Brooklyn, N. Y.

JOHN DUNN, JR., President Syracuse National Bank; President Dunn Manufacturing Co., Boots and Shoes, Auburn, N. Y., and Syracuse, N. Y.

ALVA W. PALMER, Wholesale Clothing, Syracuse, N. Y.

GUSTAVUS E. STRAUSS, Lace Importer, New York City.

GEORGE HUTCHINS, Standard Oil Company ; Capitalist, New York City.

ANTHONY N. BRADY, Capitalist ; Director Central Trust Co., Municipal Gas Co., Westchester Electric R. R. Co., etc., Albany, N. Y.

HENRY SIEBERT, Capitalist; Director in many corporations, New York City.

GUSTAVUS E. JAHN, President Rice Mills, Molasses Mills, Sugar Importer, etc., New Orleans and New York City.

HENRY D. McCORD, Capitalist; Merchant; Grain and Flour Exporter, etc., New York City.

EASTERN STANDARD TELEPHONE CO.

BOARD OF DIRECTORS.

JOHN W. CANDLER (President), Merchant; ex-President Boston Board of Trade; R. R. President; ex-Congressman, etc., Boston, Mass.

WM. GREEN ROELKER, Attorney; Electric Railway Owner, etc., Providence, R. I.

GEORGE P. WESCOTT, Bank President; President R. R., Portland, Me.

GEORGE W. HUNT, President Bank ; President Sugar Refining Co., Portland, Me.

J. M. W. HALL, Banker; Merchant; ex-Mayor, Cambridge, Mass.

FRANKLIN FAIRBANKS, ex-Governor Vermont; owner Fairbanks Scale Works, St. Johnsbury, Vt.

H. E. WELMAN, President Electric Light Co., and Merchant, Providence, R. I.

R. R. ARMSTRONG, Capitalist; Sugar Importer, New Haven, Conn., and New York.

J. A. STURSBURG, Controller; Buyer of American Sugar Refining Co., New York and Boston.

F. C. HEWITT, Banker; Sugar Importer, etc., New York.

STILLMAN F. KELLY, Sugar Importer; Molasses Manufacturer, etc., Boston, Mass.

JOSEPH B. BARTRAM, Banker; Merchant, New Haven, Conn.

THURLOW WEED BARNES, Capitalist; President parent Standard Telephone Co.; represents other parties on this Board; home, Nantucket and New York.

NEW JERSEY STANDARD TELEPHONE CO.

BOARD OF DIRECTORS.

NATHANIEL TOOKER, Capitalist; President National Sugar Refining Co.; home, New York and Orange, N. J.

LEON ABBETT, Capitalist; Attorney; home, Hoboken, N. J.

F. D. MOLLINHAUER, President Mollinhauer Sugar Refinery; home, New Jersey and New York.

AUGUST LUEDER, Capitalist; Sugar Importer; home, New York.

ELISHA B. GADDIS, Wholesale Grocer and Capitalist, etc.; home, Newark, N. J.

FRANK A. MAGOWAN, ex-Mayor Trenton, N. J.; Manufacturer, Capitalist, etc.; home, Trenton, N. J.

JAMES A. SILVEY, President Insurance Club of New York; Vice-President German-American Insurance Co.; home, New Jersey and New York.

SAMUEL KLOTZ, Capitalist; Manufacturer, etc.; home, Newark, N. J.

A. Q. GARRETTSON, Attorney; ex-Judge; Capitalist, etc.; home, Jersey City, N. J.

HOWARD S. TITUS, Manufacturer; Controller; Capitalist; home, Trenton, N. J.

GEORGE PFEIFFER, JR., Banker; Manufacturer; President Electric Light Co.; home, Camden, N. J.

OTTO THEURKAUF, F. A. Marsily & Co., New York.

THE PENNSYLVANIA STANDARD TELEPHONE COMPANY.

BOARD OF DIRECTORS.

RICHARD W. CLAY, President Solicitors' Loan & Trust Co., Philadelphia.

WILLIAM P. ARMSTRONG, Merchant, Sugar Importer, etc., New York City.

R. DALE BENSON, President Penna. Fire Ins. Co., Philadelphia.

HENRY A. BERWIND, of Berwind-White Coal Mining Co., Philadelphia.

JOHN STOREY JENKS, of Randolph & Jenks, Cotton, Philadelphia.

NICHOLAS LENNIG, President Tacony Chemical Works, Philadelphia.

CRAIGE LIPPINCOTT, President J. B. Lippincott Co., Philadelphia.

R. SELLERS McKEE, Glass Manufacturer, Pittsburg.

GEORGE MOORE, Merchant, Braddock, Pa.

HENRY P. NESSMITH, JR., Storage, New York City.

CHARLES PLATT, President Ins. Co. of North America, Philadelphia.

WINTHROP SMITH, Banker, Philadelphia.

FRANCIS RALSTON WELSH, Bonds and Securities, Philadelphia.

C. W. BERGNER, Brewer, Philadelphia.

E. L. FULLER, Capitalist; R. R. Owner; also Coal and Iron Mines.

COLUMBIAN STANDARD TELEPHONE CO.

BOARD OF DIRECTORS.

LEMON G. HINE, ex-President Mergenthaler Type Working Machine Company; ex-District Commissioner, Washington, D. C.

JUDGE POINDEXTER, Lawyer; ex-Congressman, Washington, D. C.

DR. W. W. FIERCE, Principal Medical Examiner U. S. Pension Office, Washington, D. C.

THEO. J. MEYER, of Wm. L. Galt & Co., Grain, Washington, D. C.

FRANK HUME, Wholesale Grocer, Washington, D. C.

W. O. DENISON, Real Estate and Capitalist, Washington, D. C.

CHRISTIAN HEURICH, Capitalist and Brewer, Washington. D. C.

JOHN A. HAMILTON, Capitalist and Wholesale Grocer, Washingtor, D. C.

THE RATING AND BEHAVIOR OF FUSE WIRES.*

BY W. M. STINE, H. E. GAYTES AND C. E. FREEMAN.

The thermal cut-out is still one of the most unreliable of the many devices employed on electric circuits. Its use is universal, but beyond a few practical details the device is but little understood. The blocks in which they are used show some slow improvement, but most of this has been due to the vigilance of insurance boards, and they are still far from perfect. As a source of vexation and uncertainty, the fuse is probably unrivaled.

An analysis of the literature of the subject shows that the theory of the thermal cut-out has been thoroughly investigated. The elements entering into its action have been carefully studied and incorporated into fairly satisfactory equations. Yet all tests and treatments have shown the thermal cut-out to be subject to such variations and modifying influences that but little of practical value can be deduced from analytical investigations. These considerations led the writers to attempt further investigations. The fuse was dealt with as an auxiliary to electrical circuits, and its behavior under such conditions was carefully studied.

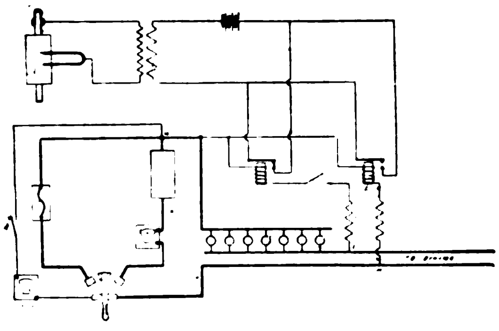

FIG. 1.

Figure 1 is a plan of the main and auxiliary apparatus, with all connections indicated. One of the dynamo leads was brought to the switch S. The carbon rheostat, C R, was built up of carbon plates, whose contact resistance was readily varied by screw pressure. The fuse was tested in a large box lined with asbestos, and open at the top, permitting of inspection and access, while at the same time protecting the fuse from draughts. The lamp rack, P, held 100 16-C. P. 110-volt incandescent lamps. These were connected in groups to switches, which enabled any combination from 1 to 100 to be used. A step-by-step rheostat in multiple with this rack was used to adjust the current through the interval of one lamp. By its use the current could be accurately adjusted within the limits of .4 and 60 amperes. For higher currents several similar racks were placed in multiple: L_1 and L_2 were small "pony" relays of 20 ohms resistance, having in series with each five 16 C. P. 110-volt lamps (R_1 and R_2). These relays worked on a current of about 10 milliamperes each, and were wired to close the circuit through the primary of the induction coil I. Two storage cells furnished the current for these relay circuits. T was an electro-magnetic tuning-fork driven by an independent storage-cell; C an iron chronograph drum which was turned by hand. The secondary or spark circuit of the induction coil was connected to the tuning-fork and the chronograph drum respectively.

The current to which the fuse was subjected during the test was first measured accurately by throwing the switch on contact O, and passing it through the Weston ammeter, A. Both the circuits passing from the jaws O and N of the switch to the point of conjunction Q were short, and of No. 4 A. W. G. wire. It was thought best to take the resistance of the fuse into account, and adjust the resistance of the ammeter circuit to exactly equal that of the fuse circuit. To accomplish this a current smaller than the known fusing current was sent through the fuse, and the fall of potential from S to Q noted on a Weston milli-voltmeter. The current was next switched on the ammeter circuit and the fall over this from S to Q was made exactly that over the fuse circuit by adjusting the compensating carbon rheostat. The fusing current being accurately measured was switched over on the fuse. The fusing time was thus accurately ascertained. The lamp rack being a non-inductive resistance, the time interval for the current to rise to its full value on the fuse is negligible for all but the very shortest periods. The resistance of the bank of incandescent lamps could not materially alter during the quick throw of the switch. To render the point more certain, the time interval between the break and make of the switch was accurately determined chronographically, and found to vary between $\frac{1}{700}$ and $\frac{1}{1500}$ of a second. The fusing times were noted on a stop watch for all periods exceeding one second. For shorter periods the chronograph arrangement was used. The tracings of the electromagnetically driven tuning-fork T were made on smoked paper fastened over the drum C. This fork was always rated before each set of experiments by switching it in circuit with a standard-second clock. Its rate was about 67 double vibrations per second. By frequent timing, all changes in rate due to temperature, etc., were noted and allowed for. The amplitude of the fork was large enough to allow periods of less than $\frac{1}{1500}$ second to be accurately measured. The records on the drum were made by sparks from the induction coil upon the breaking of one of the relay circuits.

The action of the relays was as follows: When the switch was on O, L_1 was closed and L_2 open; when the contact was broken at O, L_1 opened, throwing a spark on the drum, and L_2 closed; the switch making contact at N, L_1 closed and L_2 opened, making the second spark record; when the fuse blew, L_1 opened, causing the third spark record. Though both relays acted synchronously, there was an interval during which the current through coil I was completely broken. Two distinct records were made in every case. The interval between the first and second sparks gave the period of open circuit for the switch, while the interval for the second and third sparks gave the fusing times.

As our experiments were designed to exhibit the behavior and characteristics of the fuse used for protecting electrical circuits, it was considered best to adopt not more than two brands of wire for all the tests, rather than employ a large number of varieties. Other investigations have shown that the various makes of fuse wire closely resemble each other in behavior, and the conclusions obtained with one wire would be general for all. The first make of wire was purchased from supply houses, the second was furnished by manufacturers.

The first series of tests was made under conditions which we shall call commercial, or those which obtain in practice. In all cases the fuse wire was carefully inserted, so as to obtain a uniform pressure of the wire under the screw head without unduly crushing it. The same block was used repeatedly, and little care taken to keep the terminals clean. This was done to more nearly imitate practical conditions. In only two or three cases out of hundreds of fuses blown did the rupture occur at the contact. Two classes of porcelain cut-outs were employed; one was the open porcelain base "Main Line" style, the other the closed porcelain "K. W." variety. In the latter, the 10-ampere size has a space of only ½ inch between its terminals, though the fuse is suspended out of contact with the porcelain base. This style of block has recently been condemned by the underwriters, and very properly. Nearly all types of porcelain fuse-blocks merit severe criticism on several points. The terminals are too close together in small sizes, the fuse often resting on the top or base; and their mechanical construction is very poor. Too little attention seems to be given to the proper function of a fuse-block in its design.

Table I needs but little comment. It clearly shows the unreliability of the porcelain fuse blocks used, and also the imperfect commercial rating of the fuse wire, A. The limit of fusing time was 60 seconds. Fuses larger than five amperes will often blow in from one to three minutes on a current somewhat less than stated, but this correction is so slight for these results that it need not be seriously considered.

TABLE I.

FUSING CURRENTS IN AMPERES—LIMITING TIME ONE MINUTE.

	A ½ ampere.	A 1 ampere..	A 2 ampere..	A 3 ampere..	A 5 ampere..	A 10 ampere.	A 15 ampere.	B 4 ampere..	B 8 ampere..	B 12 ampere.

Open block, 8 inches, hor..	2	4	6	7	11	..	20	..	..	..

In the second series of tests the open 8 inch block was adopted to avoid all cooling effects from the terminals. When used horizontally, the fuse rested on a number of thin asbestos supports let into grooves one inch apart, the fuse being elevated one inch above the base of block. In those tests in which the block was placed vertically hydrostatic pressure lowered the fusing point, but when used horizontally the data may be regarded as the normal fusing points for these various wires.

The data of Table II will be clearly understood from the accompanying legends. One of our objects was to accurately measure the fusing time for abnormal currents. It is characteristic of all electro-thermal devices that they are sluggish in action. Cases may arise in practice where the insulation of wires is forced to become a fuse competing with the metal supposed to protect the circuit. In all such cases it is only a question as to which shall yield the sooner. There is sufficient evidence in this table to explain why a fuse does not always protect an armature from burning out. The table becomes the more significant in this light when it is noticed that the data has been obtained by the use of an abnormally long fuse block. With the commercial block the fusing times were increased many fold.

TABLE II.

FUSING TIMES IN SECONDS.

Ampere.	I.	II.	III.	IV.	V.

I.—20 amp. B.	Horizontal 8 in. mica supports each inch.
II.—20 amp. B.	Vertical 8 inches.
III.—20 amp. A.	Horizontal 8 in. asbestos supports each in.
IV.—20 amp. A.	Vertical 8 inches.
V.—25 amp. A.	Vertical 3 inches.

The curve obtained from three-ampere fuses indicates that a fuse is more sensitive in a covered than in an open block.

The blowing of the fuse is not immediately an electrical act. The current fuses the metal, the cross-section is reduced at some point due to gravity, unequal expansion, or "sweating"; the heat in consequence intensifies at this point, and a globule falls, breaking the circuit and establishing an arc, which soon burns out a length of the fuse. This accounts for the sluggish action of such thermal cut-outs. An ideal fuse would be one that would act at approximately a constant time interval for all currents in excess of its normal. It would in this respect closely resemble the action of an electro-magnetic cut-out. Its curve would be a straight line extending from its normal point and slightly approaching the vertical axis for all abnormal currents, being thus identical with the curve of the electro-magnetic cut-outs. In practice the curves of all thermal cut-outs must be more or less modified hyperbolas. The ideal curve could only be attained were it possible to eliminate conduction and radiation losses. This is evidently the line to follow in designing a sensitive fusing block.

---

* Abstract of a paper read at the 100th Meeting of the American Institute of Electrical Engineers, New York and Chicago, October 23, 1895.

The smaller diameters of fuse wire approach more nearly the ideal condition. This is of great practical interest in guarding against excessive currents of short duration, such as motors are subject to when operated from street railway and power circuits. In such cases a multiple fuse of four pieces of five-ampere wire would prove from two to three times as sensitive as one piece of twenty-ampere size. Such multiple fuses have been found by the writer to effectually prevent the belt slipping off the pulley of small dynamos under short circuits. The sluggishness of large fuse wires may be due to the cooling of the outer layers which, with the oxide coating, prevent the fuse from breaking. It is evident that this effect would be less in small wires. For this reason a thin ribbon should prove more sensitive than a round wire.

These tests with long lengths of wire reveal some actions which may account for the lowering of the fusing point by use. In the A wires, with a current just below the fusing value, the wires were found to "sweat;" the oxide film broke in places and allowed the molten interior to ooze out. When the current was shut off the globules were drawn in, leaving the wire pitted. With the B fuses the metal was found to be remarkably plastic and free from the oxide film. These fuses sagged badly and twisted, showing a high coefficient of expansion. As a result they were drawn out and the cross-section reduced.

When used vertically the metal flowed until a large globule formed, the rupture occurring just above this. In the case of the german-silver fuses the sweating resulted in partially breaking up the alloy, the zinc seeming to melt out from the nickel and fusing with the copper formed globules of brass. This was so marked that it would render such fuses too uncertain for use in all but the smallest diameters of wire.

The blowing current for 15 seconds of 6.3 amperes in the case of the short fuse in the open porcelain block was raised to 10 amperes. Excepting the higher fusing points, the curve of the long fuse is the same as that for the shorter length. The results obtained by shortening the fuse make it evident that the usual rating of fuse wires in ampere carrying capacity is practically valueless and should be discontinued. The proper designation for such wires would be a table of carrying capacities for the lengths ordinarily employed. The 10-ampere wire fused in 30 seconds at 15 amperes in an eight-inch length; in a length of one-half inch in a covered block at 35 amperes, and in the open block, length seven-eighth inch, at 25 amperes. Accompanying each spool of the B wire was a stated carrying capacity for a given length, but this is not sufficient since it furnishes no guide for other lengths.

Copper fuses have frequently been stated to be more prompt in action than the alloys usually employed. The copper fuses reached red and even white heat in these tests, while the other fuse wires scarcely reached a perceptible glow. This has a practical significance in selecting metals for fuse wires. Metals in general, which can be worked at or near a white heat will prove most sensitive, since a slight increase of heat will make them highly fluid, and rupture will promptly occur. The practice of using copper in street railway circuits for limit fuses seems justifiable. Whether the oxide film of copper fuses would prove progressive in formation is a question which has not been definitely settled. A 3-mil copper wire which fused at 2.2 amperes in 13 seconds was fatigued at a red heat for eight minutes; cooled and tested under the first condition, it fused at 2.2 amperes in 14 seconds.

A great deal has been said about the influence of grease films on lead fuses. This point was also investigated. The grease was removed from the wires by immersion in KOH and NaOH with subsequent washing. In other cases the wire was cleaned by the use of fine sand-paper. The oxide film was also removed by immersion in nitric acid. Measurements showed that this treatment did not sensibly reduce the cross-section. When the oxide film was removed by either mechanical or chemical means it was noticed that a thicker coating formed at once, raising the fusing point. In short, these tests showed that nothing was gained by cleaning the wires, but that the thin film of grease deposited during the drawing of the wire was rather an advantage. The wires were also coated with shellac, but without encouraging results. Some coating, not affected by heat, and which would reduce the radiation, would doubtless increase the stability and sensibility of fuse wires.

We may now summarize some of the practical conclusions deduced :

1. Covered fuses are more sensitive than open ones.

2. Fuse wire should be rated for its carrying capacity for the ordinary lengths employed.

2. (*a*) When fusing a circuit, the distance between the terminals should be considered.

3. On important circuits, fuses should be frequently renewed.

4. The inertia of a fuse for high currents must be considered when protecting special devices.

5. Fuses should be operated under normal conditions to insure certainty of results.

6. Fuses up to five amperes should be at least 1½ inches long, one-half inch to be added for each increment of five amperes capacity.

7. Round fuse wire should not be employed in excess of 30 amperes capacity. For higher currents flat ribbons exceeding four inches in length should be employed.

Breaking a Strike With a Searchlight.

A novel use has been found for the electric searchlight in connection with a strike and riot in Lancashire, England. The manufacturer whose men had struck was determined to keep his mill going, and he promptly secured new hands and set them to work. At the same time he wired to a firm in Manchester to fix a searchlight on a prominent part of the factory building, with the idea of preventing the strikers from maliciously setting fire to the temporary sheds erected for the protection of the new hands. An hour after the receipt of the order the plant was running on the top of the works, and during the continuance of the strike it was used nightly, in conjunction with the police force established in the works, to scour the surrounding country and to illuminate the various parts where pickets were placed. It was found so effective that a large number of temporary police were dispensed with.

Low Temperature and Magnetism.

The experiments made by Prof. Dewar before the British Royal Institution with low temperatures have established some interesting facts. The tensile strength of iron at 400 degrees below zero is just twice what it is at 60 degrees above. It will take a strain of 60 instead of 30 tons to the square inch, and equally curious results have come out as to the elongation of metals under these conditions.

It was an idea of Faraday, says *Cassier's Magazine*, that the magnetism in a permanent magnet would be increased at very low temperatures; and experiments with comparatively low temperatures had rather negatived Faraday's suggestion, but Prof. Dewar has completely verified the opinion of the famous savant, having shown that a magnet at the extremely low temperature made possible by the liquid air had its power increased by about 50 per cent.

NO SEAT, NO FARE, IN EUROPE.*

LONDON.

In London the intramural transportation business is done by about thirty different companies and private individuals, who operate respectively from one to one thousand vehicles. The largest of the London companies in 1894 carried 133,131,902 passengers. London has a graded system of fares, which is a very expensive system for the company. The lowest fare is a halfpenny, or one cent, and is increased according to distance, so that the passenger pays about one cent for each mile of ride. The average fare received by the company referred to during 1894 was three and one-fifth cents, or equal to six rides for twenty cents. Each vehicle requires a driver and conductor, and its capacity is generally limited to twenty-six passengers, fourteen on top and twelve inside. The Commissioner of Police is authorized to make regulations in respect to the route to be taken by each vehicle. No pictures or advertisements are permitted, unless approved by the Police Department, and they must be so placed as not to obstruct ventilation. Before each vehicle is licensed it must be brought to the police station, where it is examined by an Inspector of Public Carriages. If he is satisfied that the vehicle is "fit for public use," he gives the vehicle its number. The license specifies the number of passengers permitted to be carried, and the police regulations provide that an additional person shall not remain when warned by the conductor that the vehicle is full. The conductor is required not to permit such additional person to remain. This additional person and the conductor are each subject to a fine of not exceeding forty shillings in case of violation. Under these conditions, the company last year paid eight per cent. dividend on its stock, and also carried an amount to its surplus account. In London the cab fare for a two wheeled vehicle is one shilling—twenty-five cents—and the charges are the same for one, two or three persons, which makes serious competition for all the street railway companies. The metropolitan police district of London contains considerably over five million people, and every person who rides is furnished with a seat.

BERLIN.

In Berlin the franchise of the principal street railway company expires in 1911. During the life of this franchise the company will pay into the city treasury two times its capital stock. At 1911 all the street construction becomes the property of the city, and the horses, cars, stables, etc., may be purchased by the city at its option. All street repairs are done by the city, at the expense of the company, but, unlike American customs, the repairs are carefully and economically made. The police control the traffic in the streets in every respect. Berlin has a graded system of fares. In 1894, 131,800,000 passengers were carried by this company, for which it received an average of a trifle more than eleven pfennigs, or two and three-quarter cents per passenger, or six rides for seventeen cents. With this rate of fare, sufficient surplus is being accumulated to retire all bonds before 1911 and leave two hundred (200) per cent. for the stockholders. The stock of the company is now quoted at three hundred (300). This street car company is subject to effective competition of an omnibus company. Tickets are not sold in advance, but are given to each passenger as they pay their fare, and the police regulations require the passenger to retain and to produce such ticket on demand of the conductor or inspector. Every passenger is provided with a seat.

A COMPARISON FOR 1894.

London Company seated	133,131,902
Berlin Company seated	131,800,000
West Chicago Company freighted	85,287,302
Chicago City Company freighted	84,794,987
North Chicago Company freighted	49,571,463

---

* Report made to the Mayor and City Council of Chicago by C. L. Bonney of the Chicago General Railway.

PARIS.

In Paris the rate of fare is high, inside the vehicle being thirty centimes (which includes a transfer ticket) or six cents. The fare on top, which does not include a transfer, is however three cents. *Special* 'buses also run between the railway stations at a charge of five cents, but are not permitted to take on or let off passengers between the terminals. The competition from the hack service is a very effective one, two or three people being carried for thirty (30) cents.

In St. Petersburg and Moscow the fare is uniform; inside the cars it is two cents and a half, and on top one cent and a half. The competition of the cab service is carried on at the rate of twelve and a half cents for one or two persons.

In Christiania and Stockholm the uniform fare of ten ore—two and a half cents—is charged.

In Vienna the graded fare is from four cents up, according to distance.

In Brussels the graded fare is from two cents up, according to distance.

In all of these cities, and I believe in every other city in Europe, every passenger is provided with a seat, and the regulation is so well understood that it does not produce any disorder or complaint. In fact, the overcrowding practised in American cities would not be tolerated at all.

JOINT USE OF TRACKS.

In pioneer days the American street car privileges were declared to be legal contracts which could not be subsequently altered without consent of the street railway company, but with the progress of civilization the courts have discovered that, although the municipal body may contract or sell the property of which it is proprietor, it cannot either contract or sell the rights held by it as trustee for the whole people. The American street railway privileges are not construed to be exclusive, except when so expressly stated, and even then the rule of construction limits the exclusive rights of the railway company, as much as possible, in favor of the people. The principle that the people own the fee of the streets, and that the municipal body may grant to a new railway company the right to use the tracks of the old company upon paying compensation, has been developed in Ohio and Massachusetts to a praiseworthy extent. The Supreme Court of Illinois now holds that the ordinances of the city council granting street railway privileges are not franchises but mere licenses. In nearly all of the American cities some old railway company has occupied the principal streets with tracks, and in many cases has not operated the same until some new company offered competition, then the agents of the old company would preach to the signers of frontage that as the new-born company was neither big nor rich it should not be allowed to live. If the new ordinance was secured, the new company would be notified that its franchise would be "smashed," and bogus injunctions would then be brought to sink the new-born in a mire of lawyers' fees and court costs, and every struggle of the new-born to exist would be branded as blackmail to force the old company to buy out the new. This condition of affairs naturally led to the new law of Ohio and Massachusetts. The above data indicate that in the European cities competition is fostered and monopoly discouraged, but it is not so in the American cities, except in theory.

GENERAL LAWS, NOT INDIVIDUAL PRIVILEGES.

I have to petition your honorable body that the general ordinances relating to street railway licenses be revised by the City Law Department, and in which it shall be declared to be the public policy of the city not to renew or extend any street railway "contracts" after the original terms of the same shall expire, but that "licenses" may thereafter be issued under the general law by the City Clerk, and subject to such general laws, to any person, firm or corporation who may apply for the same to operate a street car, as is done with hacks and other vehicles used by common carriers; the movement of such cars on the public street to be under the control and regulation of the Superintendent of Police. That a license fee of .... dollars be charged for each car, which license shall be posted in the car for which it is issued, and that one-half of all license fees collected may be used by the Commissioner of Public Works in keeping the tracks now laid, or to be laid, in proper repair. The Police Department should also have authority to require vestibule cars for the protection of smokers and employees.

MUNICIPAL OWNERSHIP.

The proposed general ordinance should distinguish between municipal ownership and municipal regulation; the former should include everything attached to the public highway—track, poles, wires and everything which the Police Department may desire to change or remove at any time. The latter should relate to the movable private property of the street car company, as the same may be engaged in public service on the public street. I do not think the city should attempt to own or operate the vehicles in which the business of the common carrier is conducted. I am informed that such a system is now in operation in Toronto and with great success. In case a new company also desired to use the cable or trolley power of an old company, the running arrangements should be made by the Superintendent of Police, and the old company should receive compensation from the new company on a mileage basis. This complication will not long exist, however, as several independent motors are nearly ready for the market, which will do away with both cable and trolley.

In this general ordinance the construction of tracks can be declared to be a local improvement, which, under our constitution can be constructed like water and sewer mains, by special assessment on the property benefited. If the majority of the owners of the land fronting on the street where said tracks are proposed to be constructed petition for the construction of such tracks, the ordinances for the same may be passed as in other special assessment cases. Such a system would not only encourage competition and discourage monopoly, but would remove the scandal which sometimes attaches to the railroad company when it receives an individual street railway franchise. Such a system would also give double protection to the majority of abutting land owners about whose right to enjoin the old companies of this city are now much worried.

1. Tracks will not be constructed on any street unless the majority ask for it.

2. If the majority ask for the tracks, it is not probable that the old companies would influence the suppression of the improvement, as it and every other company, individual or real estate speculator, would be entitled to run independent cars on such tracks under the general license ordinances above proposed.

In the European cities roads are built for the profits of regular operation, but in the American cities the profits of construction are the first consideration. Watered stocks, windy debentures and mortgage securities are issued to so large an amount that many American companies cannot pay expenses and fixed charges, much less make money, even with a five-cent fare. The company with which I am connected has, for more than two years, carried passengers, under unfavorable circumstances, for six rides for twenty-five cents, or a nominal four-cent fare, and has paid all its operating expenses and fixed charges.

The so-called sale of franchises to the highest bidder should not be established, as in so doing none but the very rich could buy. The principle of paying the cities a gross sum for a "supposed franchise" is also bad, as it perpetuates the idea of a privileged monopoly as against the license theory. Why should not the people themselves, through whose territory the road runs, be entitled to some of the direct benefits, as by a reduction of fare, improved service, or other advantages which would naturally come out of fostered competition?

G. E. EXPLOITING WORK.

OBJECT LESSONS—THE CHARACTER OF ESTABLISHED STATIONS.

Samples of the Facilities Afforded to Local Enterprises.

[The Edison Company, to a small extent, and the T.-H. Company (the organization of which was mainly adopted by your company), to a greater extent, had been in the habit of doing more or less exploiting work, resulting in the acquisition of stocks and bonds of local lighting and railway companies. By the facilities which it had thus been able to afford to local enterprises it was enabled to expand its business.—*G. E. Company's Annual Report, 1894.*]

CHAPTER I.

In a series of articles running through the past three months, ELECTRICITY has been able to show, from the official records, the character of the local enterprises to which Mr. Coffin's agents devoted their attention and the financial results thereof.

This week we lay before our readers proof of a different kind, fully as conclusive and vastly more entertaining than the plain figures which we have printed. This is in the shape of letters from the successive managers of the Austin, Minn., station to the home office, making up a brilliant word picture of the condition of this plant, on which Mr. Coffin and Mr. Byllesby planned to float $100,000 of securities, and various other documents relating to the affairs of the company. This correspondence begins a few months after Mr. Byllesby bought the plant of Pierce Bros., and will be continued down to the time of the Northwest G. E. Co.'s collapse.

During the first few months the Northwest G. E. Co. was successful in floating a good many bonds. Money was plenty, and the local companies received all assistance necessary. Later, as money became scarce, all the local properties established by Mr. Coffin's exploiters went through the same experience. They went from bad to worse, and were sold out at any price offered—with few exceptions. One of the exceptions was the Austin plant, which Mr. Coffin has been unable to sell, and which he still owns.

The correspondence is all worthy of careful perusal. The first few letters are found written on the old stationery of Pierce Bros.

Austin Electric Light and Power Company.
Pierce Brothers, Proprietors.
Austin, Minn., May 14th, 1892.

Mr. W. H. Moore,
405 Sibley St., St. Paul, Minn.

Dear Sir: Some one in Austin is circulating the report that two dollars per light for wiring complete is extortionate, so that four names on the list have declined to let me wire their houses at that rate. One man asked for the privilege of having his house wired by some one else. I told him he could, but that we would not light his house unless the work was satisfactory to us. They have made inquiry as to prices in the neighboring towns and say that work is done for a dollar and a quarter a light. I have argued with them but to no effect. There is a rumor that the city will buy some second-hand arc machinery and run their own lights in connection with the water works. Hoping to hear from you soon in regard to the above information, I am yours truly,

GLOVER F. PERIN, Manager.

C. L. Dering, Coal, 175 Dearborn St.,
Chicago, June 7th, 1892.

Austin Electric Light and Power Company.

Gentlemen: Yours under date of the 4th is received and noted. The regular terms of coal shipments are as stated in our circulars and in our invoices, payments due the 10th of the month following shipments. We are obliged to have our money in approximately at this time, in order to meet our mine pay-roll which is due the 15th of the month.

We will not make sight draft on you, but would request that you conform as closely as possible to our date; sometimes you will find that it gives you more than thirty days and sometimes less.

Yours very truly,
C. L. DERING.

Austin Electric Light and Power Company.
Pierce Bros., Proprietors.
Austin, Minn., June 25th, 1892.

W. H. Moore, Esq.

Dear Sir: Will you send check to B. Farrington, $60, and Fred Rettig, $40, for wages, or should pay here. Their pay is due to-day. It is collection time for June. Shall I deposit in bank to acc't of N. W. T. H. Elec. Co., or will you have account changed to "Austin Elec. Co.?" Must know so I can deposit. Alchon Bros. have two arc lamps. The past two or three months, at least once in each month the lamps have been out on account of broken circuit. They have always paid full bills—but they want some incandescents put in to use only when arcs are out. This is no more than fair. Shall I have them put in? Will send you the first of the week memorandum of items, as requested; could not do so to-day. Please advise me on above points immediately and oblige yours truly,

Wm. M. Howe.

Austin, Minn., July 1st, 1892.

W. H. Moore, Esq.

Dear Sir: Enclosed find freight bill for one car of coal. This should be paid at once. I also enclose you blank check on Austin Nat'l Bank—as I suppose you will wish to draw on this bank. I also suppose the bank will require your signature. Do you want a check book? If so will send you one at once by mail. Yours truly,

Wm. M. Howe.

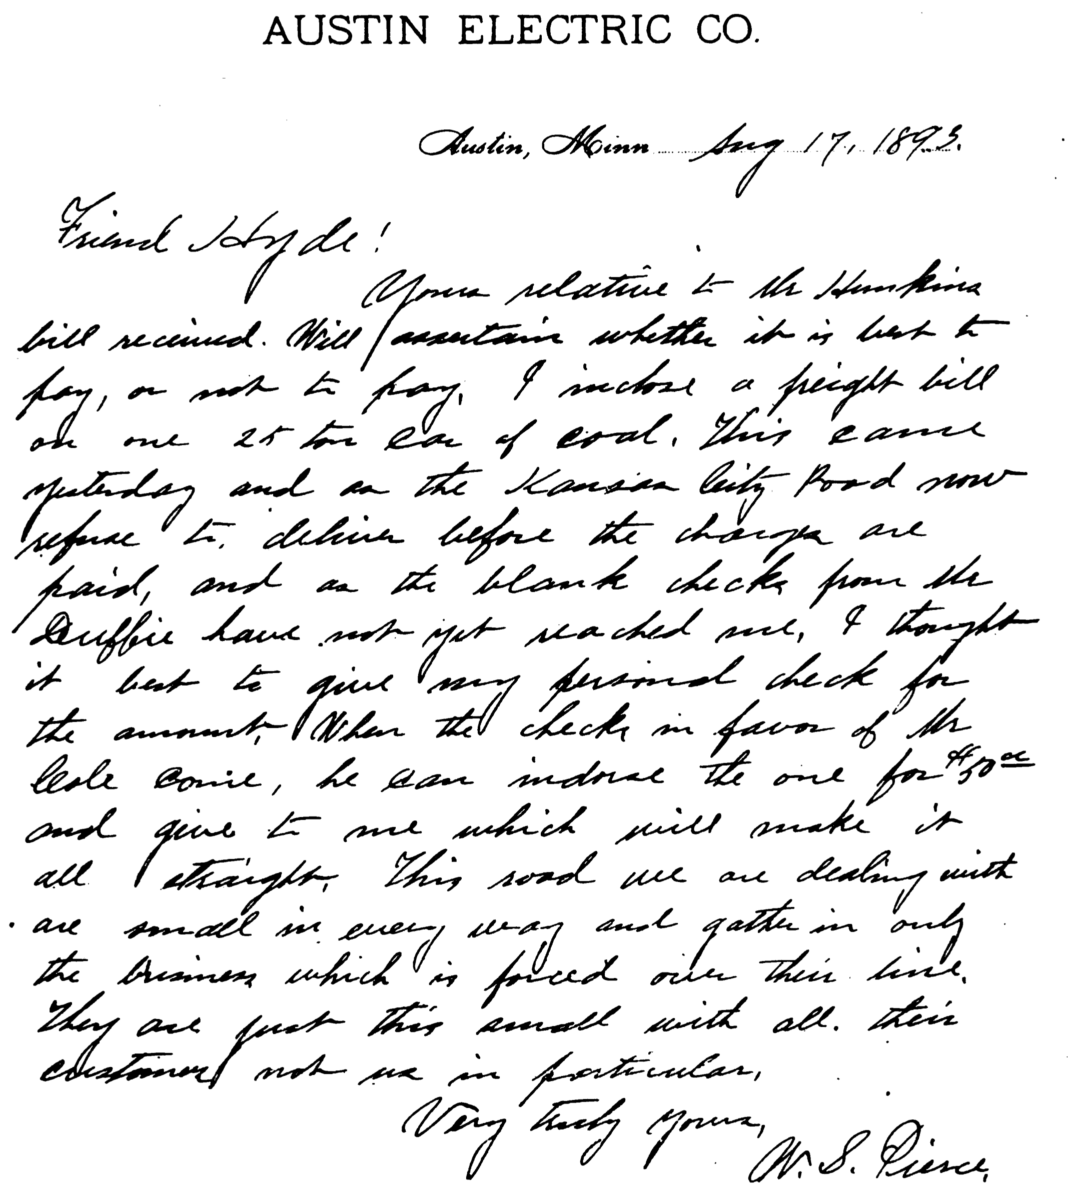
Austin, Minn., July 9th, 1892.

W. H. Moore, Esq.

Dear Sir: I herewith enclose memorandum showing part collections and all expenses as far as I have them to July 1st, 1892. The bills taken by and sent to you are not included as I keep no account of them. When I get through June collections as far as can be will send you memorandum showing amounts received for arcs and incandescents. I also return you voucher for freight on one car of coal and also statement of Robinson & Cary Co., which bill you took to pay from St. Paul, 6—4, 1892. Please send checks for bills sent you, as parties are not very well satisfied to wait. The account in bank has been changed to Austin Electric Company.

Yours truly,

Wm. M. Howe.



AUSTIN ELECTRIC CO.

Austin, Minn Aug 17, 1893.

Friend Hyde!

Yours relative to Mr Hunkins bill received. Will ascertain whether it is best to pay, or not to pay. I inclose a freight bill on one 25 ton car of coal. This came yesterday and as the Kansas City Road now refuse to deliver before the charges are paid, and as the blank checks from Mr Duffie have not yet reached me, I thought it best to give my personal check for the amount. When the checks in favor of Mr Cole come, he can indorse the one for $50.00 and give to me which will make it all straight. This road we are dealing with are small in every way and gather in only the business which is forced over their line. They are just this small with all their customers not us in particular,

Very truly yours,

W. S. Pierce,

Austin Electric Co.,
Austin, Minn., Aug. 30th, 1892.

W. H. Moore, Esq.,
403 Sibley Street., St. Paul, Minn.

Dear Sir: Your letter of the 29th inst. received The following is the pay-roll for August:

G. F. Perin,	$75.00.
B. Farrington,	60.00.
F. Rettig,	40.00.
S. A. Johnson,	35.00.

Yours very truly,

G. F. Perin.

Austin, Minn., Sept. 13th, 1892.

W. H. Moore, Esq.,
403 Sibley St., St. Paul, Minn.

Dear Sir: I received your letter of the 9th inst., also check for Rettig the voucher for which I return by this mail. If you have any idea of putting in a compound engine I should think it advisable to put in two new boilers 100 h. p. each, built to carry 125 lbs. of steam; the Ball engine would be more efficient working under that pressure by cutting off earlier in the stroke. Johnson is back at work. I have put him in the station and he bids fair to be a good man in that capacity; he and Farrington get along very nicely. Neither the poles or the coal have come yet. Will you please write Linges, Conwells & Co., and hurry them up about those fire door arches you ordered. I met Mr. Claussen to-day and assisted him as much as I could. Mr. Robertson came down Monday night and I showed him around.

I have made a canvass of the third ward and got the promise of thirty odd lights.

The station agent of the Milwaukee, Mr. Wenham, said if I would get a written proposition from you to wire 40 lights to run all night on meter basis in R.R. Hotel, station and freight houses he would endorse it and send it in to the proper authority; he expects a close figure on the wiring. I learned from Mr. Glenn, attorney for the man who owns the Missoula Electric Co., that the N. W. Gen. Co. were negotiating for purchase of that plant. I know a good many people in Missoula and would like to go out there if the deal is made. Please keep me in mind when you want to send a man out there.

Yours very truly,

G. F. Perin

Austin Electric Co.,
Austin, Minn., Oct. 4th, 1892.

W. H. Moore, Esq.,
403 Sibley St., St. Paul, Minn.

Dear Sir: Your letter of the 29th inst. received. No dynamo has come here by mistake. Nor have the poles come yet. In answer to Mr. Pratt's note about Johnson's time, the construction work mentioned was on inside wiring, and 21 days were in the capacity of a fireman and lamp trimmer. Enclosed you will find collection list amounting to $475.99, also five duplicate deposit slips, also receipted bills amounting to $1,292. Yours very truly,

G. F. Perin.

Lyman D. Baird, Attorney at Law.
Austin, Minn., Jan. 21st, 1893.

W. H. Moore, Esq.,
403 Sibley St., St. Paul, Minn.

Dear Sir: The old management of Pierce & Howe did not charge me enough at my house or else the new management are charging me too much, for while using less light the bills are double what they were in '91, and this with the same meter.

Matters are ripe here for a general shut-off, but I do not care to lead in any such movement and ask you for an explanation. You know that lights were put into the dwellings here on my recommendation as to the expense, etc., and it now looks as though I had been made a tool of. Resp'y yours,

Lyman D. Baird.

Austin Electric Co.,
Austin, Minn., March 22, 1893.

Geo. C. Duffie, Esq.,
403 Sibley St., St. Paul, Minn.

Dear Sir: I notified the men that the company would dispense with their services after July 1st They went uptown and asked the merchants to sign a petition to the company to retain them in their employ. Friday afternoon they began to abuse the company and me for not keeping them, and a little before time to start up called for their time, which I gave them, nine days each, $18.00 and $12.00. I ran the station alone Friday night and wired Mr Lehmann to come down. They tried to have me arrested for running without an engineer's certificate, but the boiler inspector declined to do it knowing that I had a certificate. Will you please send two checks to bank for the amount of their pay. Every thing is running smoothly. Hoping my action in matter will meet with your approval, I am yours very truly,

G. F. Perin.

Austin, June 25.

Mr. Duffey.

Dear Sir: I tought I would write you to see what the reason was you did not com down you know you promest me you would be down in a few days. Well I don't think you are running your Plant Mr. Cheaper then you was when I was thair? I see they have a man hired to trim the Lamps and Perin has a man hired to Straiten up his books.

I don't wonder at that the way Perin is drinking every night.

It seemes queer to me that the compney would discharge me without any cause and all ways trid to make the Plant a sucess and keep a man like Perin this has disspointed me teribel had bought Property and was to Pay quartly never thinking that I would bee discharged while I give good sadsfaction and do my work in good shape and take a strange man [illegible] is all for this time hopes to hear from you. Please ancer drect to

Barney Farington.
Austin

Austin Electric Co.
Austin, Minn., July 19, 1893.

Geo. C. Duffie.

Dear Sir: Inclosed please find daily report. We are very *low* on coal, having nothing but slack which will run not more than four nights including this evening. The coal can not be pushed too fast. I'm at work picking up the threads of the business. The situation is bilious, but nevertheless I have the promise of a goodly increase the first of next month. I have secured four old customers, who will go into circuit the first of Aug. I shall eventually get nearly all the old back and some new ones. It will take a little time, so we must not expect a rebound in one week or two. All is running well.

Yours very truly, W. S. PIERCE.

Austin, Minn., July 20, 1893.

C. B. Hyde.

My Dear Sir: Yours of July 20th at hand, and am surprised at its contents. Perin turned the plant over to me Monday, July 17th, and left here as I supposed for St. Paul, Tuesday the 18th. I could not find out from his books how much uncollected money belonged to the company or how much collected money was in his possession. The books were, as he said, not brought down to date, and claimed he would have to take the books with him to St. Paul, because he could not make his final report without, and inasmuch as he was responsible as an employee of the company, he insisted on taking the books to the company. He claimed, however, he would reach St. Paul Tuesday, and if you see fit you could return the books to me at once. It is now evening, and I can't report how much is in the bank. Will see in the morning. I have been at work helping put in a job of lighting to-day, and have been around the town none at all; in fact I did not mistrust anything exceptional and hence was not on guard. Things are in such fearful shape all over the city that I hardly know what to tackle first. Perin took his bank book with the rest of the books. The readings of the meters were on the meter book, and how I can find out what they were without the old book is more than I know unless it be from the old receipts the customers have. If Perin shows up please let me know at once. Very truly yours,

W. S. PIERCE.

Austin, Minn., July 22, 1893.

G. C. Duffie.

Dear Sir: Inclosed please find two freight bills on coal. It is necessary that a draft for this amount be forwarded at once, because any delay in such bills will not be tolerated by the freight agent here. Please ship immediately 2,000 7-16″ plain carbons. We are very low on these, so the shipment must be made promptly. Yours very truly,

W. S. PIERCE.

Austin, Minn., July 24, 1893.

G. C. Duffie.

Dear Sir: Inclosed please find a package of small bills which were here when I took possession. I have no way of telling whether these are correct or not, hence I have not O K'd the same. I believe, however, these bills are due, because Perin claims they are. Perin is here but for what purpose I cannot find out. Please send down the uncollected bills and I will try and get them collected up. Everything running well. Shall take on more lights the first of the month. Yours truly,

W. S. PIERCE.

STATEMENT.

THE ANSONIA ELECTRIC CO.

(Formerly the Electrical Supply Co.)

Draw on you to-day for above.

. Birum & Birum, Dealers in General Hardware, &c.
Austin, Minn., July 31, 1893.

Mr. George C. Duffy,
St. Paul, Minn.

Dear Sir: Enclosed find bill for $13.05 which we have on our books due us from the Austin Electric Lt. Company. Please send draft for this and oblige.

Yours truly,
BIRUM & BIRUM.

Austin Electric Co.
Austin, Minn., August 9. 1893.

Mr. George C. Duffie.

Dear Sir: When I took hold here I supposed the dynamos were in good condition, but by close inspection I find one of the alternators has been badly injured. The Perin crew overheated the armature and then tried to repair the same, yet their efforts were not successful. The armature will necessarily have to go to the repair shop. There is no hurry however, and I speak of this now so it will be understood that we have not injured the machine, or even run it at all. Yours truly,

W. S. PIERCE.

Extract from local paper, August 8, 1893.

Last night owing to an accident at the power house all the electric lights went out. It was pretty dark and late pedestrians were left to feel their way home. When the new engine is ready for business this kind of a mishap cannot take place.

Austin, Minn., August 9, 1893.

Geo. C. Duffie: Yours of Aug. 7th at hand. Will see you the next time I am in the city, say about September 5th, and then talk the situation over.

If these times continue much longer, people here will have no use for any light, and will simply go back into old night. Have taken about $50 worth of new business. Things are in much worse shape than has ever been told. Tell Mr. Hyde the voucher for oil at 9 cents per gallon was kerosene, and I enclose one to-day for the machine oil. The motors which were shipped and billed here I can not find in the city. The last seen of them was in the Masonic Hall just before Perin left, and it is supposed he took them with him. I will make further search as soon as possible, yet I think they are not here now. Can we exchange some meters for sockets, lamps and transformers? If so I will ship up a train load.

Very truly yours
W. S. PIERCE.

Austin, Minn., August 11, 1893.

C. R. Hyde.

Dear Sir: Inclosed please find deposit check for $12.70 which is for the goods attached by us to secure a lighting claim of $17.70. These goods have been sold and after paying costs there remains the $12.70 which I have placed on deposit. This affair took place before I came here. I have ordered the sight draft returned. Those motors I can not find in the whole town. Very truly yours,

W. S. PIERCE.

Austin, Minn., August 13.

C. R. Hyde.

Dear Sir: Enclosed please find a bill handed me by H. Hunkins for labor contracted by Mr. Perin. I have investigated this matter and find the actual work has been done and the fellow has not been paid. If there is a shortage of money here, so we can not reasonably check this month, you can date the check ahead to September 2d, so I can get in another collection, or I will pay the bill myself if you so desire.

Yours truly,
W. S. PIERCE.

Gentlemen:-

The Ansonia Electric Co. has drawn on you for $20 and exchange. Kindly give this your attention and oblige

Yours truly,
N. F. BANFIELD, Cashier.

MEM.—This must receive prompt attention.
W. S. PIERCE.

Austin Electric Company.
Austin, Minn.. Aug. 9th, 1893.

C. R. Hyde.

Dear Sir: I found a 15 light transformer out on the lines not in use which I took down and put up in the place where I have just finished a small job of 5 lights; so there is no hurry at present. I send you with to-day's report a list of small accounts not collected when I made out the monthly report; this ought to be added to the July collection. There are only two uncollected bills for July at this time, each $1.00, making only $2.00 outstanding, except two or three on the delinquent list sent here by you. As the meters were read by Perin the 8th of July, it cuts down the receipts for July. Next report we will make a better showing. There is a sight draft here in favor of the Ansonia Electric Company, amount $20.00. Please send check at once and oblige

Yours very truly,
W. S. PIERCE.

Free Lectures on Electricity.

Prof. A. L. Arey of the Free Academy of Rochester, N. Y., will give free evening lectures to a class of electricians during the winter months.

The McKeesport Case.

The Long-Delayed Decision Handed Down.

The United States Supreme Court has decided the case of the Consolidated Electric Light Company against the McKeesport Light Company in favor of the defendants. The Court holds the Sawyer-Man patent invalid. The decision was handed down by Judge Brown.

The patent in suit is United States Patent No. 317,676, dated May 12, 1883, granted upon the application of Wm. E. Sawyer and Albon Man to their assignee, the Electro Dynamic Light Company, for an improvement in electric lamps, and assigned to the Consolidated Company.

The bill was filed December 8, 1887, and is in the usual form, setting forth the granting of a patent and its assignment to the complainant, and alleging infringement by the defendant. The defendant answered the bill, setting up the usual defences, and, in addition, certain special defences which will be considered fully further on. Issue was joined; proofs were taken by both parties, and the case was held at final hearing on the pleadings and proofs by Mr. Justice Bradley and Judge McKennan, and an opinion was filed on October 5, 1889, holding the patent in suit to be invalid and directing the bill to be dismissed. A final decree was entered in accordance with the opinion on October 10, 1890, and from this decree the complainant appealed to the Supreme Court.

The questions involved on the appeal relate to the validity of the Sawyer and Man patent in suit, the proper constructions of the claims of the patent and infringement by the defendant.

The errors relied upon by the appellant were as follows:

1, The Court below erred in giving too broad a construction to the claims of the patent in suit; 2, in holding that the claims of the patent in suit were void for lack of novelty; 3, in not following the adjudication of the Patent Office on the issue of priority of invention between Sawyer and Man and Edison with respect to the invention in suit; 4, in holding the evidence that Sawyer and Man made the invention in suit prior to Edison to be insufficient; 5, in holding that the invention covered by the claims in suit was not patentable; 6, in holding that the claims of the patent in suit were for a different invention from what was described in the original application for the patent, and that the amendments to the original applications which were made in the Patent Office were not justifiable; 7, in not holding the patent in suit to be valid and to have been infringed by the defendant, and in not granting a decree for an injunction and an accounting as prayed in the bill.

This is a negative victory for the Edison interests, though an important one for them, in that they are saved from paying several hundred thousand dollars for past damages for infringement.

As to the future the decision has no interest for any one; the incandescent lamp field is now free forever.

American Institute of Electrical Engineers.

The 101st meeting of the American Institute of Electrical Engineers, to be held on November 20th, will be devoted to a discussion of the "Storage Battery Outlook." All members having information to impart, bearing upon this subject, are invited to contribute toward a better understanding of the possibilities of the accumulator.

The Henry Electrical Club.

At the weekly meeting, on the 8th inst., of the Henry Electrical Club, at the rooms of the American Institute, New York City, Mr. Joseph Sachs gave an illustrated lecture on "Systems of Dynamo Regulation."

Removal.

Coleman Sellers, E. D., consulting engineer, and Horace W. Sellers, architect and engineer, have removed to rooms 537–539 Philadelphia Bourse.

LEGAL NOTES.

Abraded Insulation is Negligence.

Justice Lathrop of the Supreme Judicial Court of Massachusetts has just rendered an opinion which cannot fail to be of interest to electric lighting men. A tinsmith named Griffin, while engaged in placing an iron conductor on a building in Springfield, Mass., came in contact with a live wire the insulation of which had become abraded. He sustained a severe shock and instituted suit for damages against the owners of the wire, the United Electric Light Company of Springfield. In the lower court the verdict was for the defendant. When the case was appealed, Justice Lathrop reversed the finding of the lower court. In his opinion he said:

"The plaintiff was not a trespasser or a mere licensee, who must take the premises of another as he finds them. He was rightfully on the premises for purposes of business. On these premises the defendant had rightly placed two electric wires. These were a source of danger unless properly insulated. This fact was recognized by the defendant by insulating them. But it was negligent if it failed to use reasonable diligence in seeing that its wires were kept in a state of repair. This duty it owed at least to every person who, for purposes of business, was rightfully upon the premises."

An action was begun at St. Paul, Minn., on the 1st inst., by Thomas Wallace, Jr., against the Carpenter Electric Heating and Manufacturing Company and the American Electric Heating Corporation to recover from the second named defendant $5,587 under the law relating to the liability of stockholders. The plaintiff claims to have just secured a judgment for the amount named against the first named defendant, but that an execution was returned unsatisfied, and the American Corporation holding $250,000 of the $400,000 stock of the Carpenter Company, he demands judgment against the former.

Judge Lawrence, of the New York Supreme Court has dissolved the Electrical and Mechanical Engineering Company, of No. 41 Cortlandt street, and made the temporary receiver, Jonathan H. Vail, permanent receiver.

Joseph Donaldson, manufacturer of gas and electric fixtures at No. 74 East Ninth street, New York, has made an assignment. Liabilities, $23,672; nominal assets, $28,022; actual assets, $7,157.

Personal.

J. G. Ihmsen, manager of the Keystone Telephone Company, Pittsburg, was a New York visitor last week.

W. H. Webb, the Solar Carbon missionary, was distributing tracts and gathering in orders on Manhattan Island last week.

European Agency for Walker Company.

An agreement has been entered into between the Walker Manufacturing Company of Cleveland and F. De La Briere and C. La Blanc, representing a group of capitalists of Paris, whereby the apparatus of the Walker Company is to be extensively introduced into Europe.

GENERAL NEWS.

What is Going On in the Electrical World.

Little Valley, N. Y.—It is proposed to bond the town for $7,000 for municipal electric lights.

Heyworth, Ill.—J. L. Humphreys' grain elevator and electric light plant were recently destroyed by fire.

Catawissa, Pa.—By a vote of 307 to 59 the citizens of this borough have voted in favor of a municipal electric light plant.

Uhrichsville, O.—The franchise for an electric line between Uhrichsville and New Philadelphia has been given to C. E. Michener.

Alexandria, Can.—The town council has entered into a contract with Ahearn & Soper, of Ottawa, to furnish electric lights for the streets.

Bessemer, Ala.—It is probable that the Electric Light Company will get control of the street railway and change it to an electric line.

Burlington, Vt.—The mayor's veto of the franchise granted to the Columbian United Electric Company has been sustained by the Board of Aldermen.

Montesano, Wash.—The city council has passed an ordinance granting to Albert Daub a 15-year franchise for operating an electric light plant.

Valatie, N. Y.—The trustees have entered into an agreement with Robert P. Richmond to light the streets of this village with sixty 25 C. P. electric lights.

Unionville, Mo.—A committee of citizens has been appointed to confer with the city council on a proposed issue of bonds for water works and electric lights.

Toluca, Mex.—It is proposed to introduce electric lighting in Toluca, capital of the State of Mexico, employing power generators at neighboring water falls.

Ontonagon, Mich.—At a special election held for the purpose the citizens voted to bond the village for $12,000 for the purpose of putting in an electric light system.

Los Angeles, Cal.—The council has passed the final ordinance granting to the Los Angeles Traction Company a franchise for an electric railway in Eighth street.

Lafayette, La.—Proposals are wanted until November 20 for surveys, maps and estimates for waterworks and electric light plant. T. M. Biossat will furnish information.

North Wilkesboro, N. C.—W. F. Trogdon, North Wilkesboro, wants estimates on cost of transmitting by electricity 100 horse power a distance of one and one-half miles.

Richmond, Va.—The Traction Company have about 200 hands employed in the construction of the new trolley line in Broad street and to the Exposition grounds.

Skaneateles, N. Y.—The village trustees have granted to the Auburn Inter-Urban Railway Company a franchise to lay and operate an electric surface railroad in this village.

Kansas City, Mo.—The Missouri, Kansas & Texas Trust Company and the Metropolitan Street Railway Company are rival applicants for an electric car line on Wyandotte street.

Cincinnati, O.—Manager Heck of the "Zoo" recommends putting in a new electric light plant of capacity sufficient to light the entire grounds and all the buildings, to cost about $20,000.

Woburn, Mass.—It is reported that the Woburn Electric Light Company is about ready to liquidate all indebtedness, and that it will continue the business after a thorough reorganization.

Tarrytown, N. Y.—Two companies have made application to the board of trustees for a franchise to build an electric railroad in this village to connect with the White Plains road at Elmsford.

Mankato, Minn.—C. L. Alleman and S. R. Snow will ask the council for a franchise for a combined electric street railway, electric light and steam heating plant, to be built and operated as soon as possible.

Halifax, N. S.—Preparations have been made to lay the rails for the electric tramway immediately on their arrival from New York; the cars and equipment generally are expected to be first class.

Hagerstown, Md.—The Hagerstown and Potomac Electric Railway Company has reorganized, with the following local directors: Peter J. Mayberry, John H. Blake, Albert J. Everly and McKinley B. Embrey.

Long Branch.—The Long Branch Lighting Company's plant has been bought by the Consolidated Gas Company of New Jersey, and the latter has assumed control of the plant here. There will be no change in the local management.

Tennallytown, Md.—The Potomac Electric Light and Power Company has secured the contract to light this city by electricity. They will immediately string overhead wires and erect seventy electric lights in place of the naphtha lamps now in use.

Worthington, Minn.—Work on the city electric light plant is well under way and the lights will be turned on about December 10. About 400 private lights have been ordered by citizens, and the city will use eight arcs, besides several on the court-house.

Scranton, Pa.—The Delaware, Lackawanna & Western Company have demonstrated the success of electric motive power in mining operations at their Bellevue shaft, and will introduce the electric system of haulage in all their mines in this section.

Athens, Ga.—This city is now experimenting in the operation of its own arc light plant, recently purchased from the owners here for $9,000. The incandescent plant is now owned by Mr. R. L. Bloomfield, president of the Athens Manufacturing Company.

West Chester Pa.—The representatives of a party of Philadelphia and New York capitalists are interviewing the farmers between this place and Quarryville, Lancaster county, relative to securing the rights of way between these points for an electric railway.

East Orange, N. J.—The Suburban Electric Light & Power Company, an East Orange corporation, has applied to the township committee for an electric light franchise and for authority to lay underground conduits for the transmission of their current.

Jacksonville, Fla.—J. F. Eldridge, treasurer of the town of Orange Park, states that Boston and Chicago capitalists are interested in the projected electric railroad between Jacksonville and Orange Park, and there is every indication of its early construction.

Moreland, Cal.—At a meeting held here recently to get the views of the people as to contributing aid to the proposed San Jose and Saratoga Electric Railroad it was decided to raise a fund of $50,000 for the purpose. L. M. Hale, of San Jose, is an active promoter of the railway project.

Standish, Mich.—Beecher Kimbel, of Au Sable, has asked the council for a twenty-five-year franchise for an electric light plant. He says he will light the city for $48 a year per lamp and furnish it to business houses for 75 cents per month. It is thought that his offer will be accepted.

Salida, Col.—The Edison Electric Light Company have sold their entire plant to the Mountain Electric Company of Denver. All local interests have been sold and all property and franchises pass into the hands of the new company. Mr. Bentley, of Florence, will be the new manager.

South Braintree, Mass.—It is reported that the New York, New Haven & Hartford Railroad Company will at once commence the erection of repair shops and a large power house here to furnish electric power for the proposed line between this place and Boston to be operated by electricity.

Rutherford, N. J.—A franchise has been granted to New York and Philadelphia capitalists connected with the Union Traction Company of New Jersey under which that company can begin the construction of its proposed trolley line from Rutherford to Newark, a distance of fifteen miles.

New York.—The Madison Avenue Street Car Company will have two cars fitted with storage batteries in regular service on its line in a few days. One of the cars has been run over the line already and worked without a hitch of any kind. If the experimental cars prove a success after sufficient trial all the cars on the line will be similarly equipped.

Quebec, Can.—Canadian capitalists are interesting themselves in the project of an electric street railway in Buenos Ayres, Argentine Republic. The city has 750,000 inhabitants, and there are only two streets in which the electric company has not the right to lay down tracks. Canadian trade with the Argentine Republic is now $4,000,000 a year.

Wakefield, Mass.—A company to be known as the Peabody, Lynnfield & Wakefield Street Railway Company has been formed to build an electric railroad from Peabody to Wakefield through Lynnfield. The men interested in it are B. W. Russell, Daniel Low, Thomas H. Johnson, of Salem, with J. M. Danforth, of Lynnfield, and E. P. Shaw, of Newburyport.

Biwabic, Minn.—Steps have been taken to incorporate this place as a city so as to enable it to sell bonds and use the money for improvements. It is proposed to raise at least $10,000 in this way, put in an electric light plant, extend the water system, improve the streets, etc. Biwabic is a mining town.

Benton Harbor, Mich.—A franchise for a new electric street railway company will be asked of this city probably at the next regular meeting, December 4. The line will run from the City Hall on Main street to Easton Springs. The enterprise is backed by a syndicate of Chicago and local capitalists.

Philadelphia.—The stockholders of the People's Traction Company at a recent meeting decided to reduce the capital stock of the company from $10,000,000 to $6,000,000. This action makes the par of the stock $30 instead of $50, so that it is now full paid and subject to no further calls.

Beverly, Mass.—The old storage battery railway between Beverly and Danvers, which failed in operation and was abandoned three years ago, is now being repaired. It has come into the possession of the Lynn & Boston Street Railway Company who will equip it with the trolley system and operate it.

Trempealeau, Wis.—Business men here will make an effort at the next session of the Legislature to have an appropriation made for improving the Trempealeau river so as to make it navigable for canal boats and smaller craft. The next step will be to fit out a trolley electric system for running the canal boats.

New Haven, Conn.—The "Leader" states that it is announced "that a new electric railroad is to be built and put in condition to operate by early spring. It will connect existing lines in Hartford with the city of Rockville, thus making a through line from the capital city to one of the most bustling centers of the State."

Beatrice, Neb.—The consolidation of the two electric companies here has been completed and the new concern will be known as the Beatrice Electric Company. The capital stock is fixed at $100,000. The officers are: J. A. Horbach, president; J. E. Smith, vice-president; A. S. Maxwell, secretary; Paul W. Horbach, treasurer.

Winona, Minn.—The profiles and plans of the projected electric railway from La Crosse to Neillsville, through Black River Falls and Merrillan, about 70 miles, have been nearly completed in the office of Engineer Pickles in this city. The company projecting the road will decide this winter whether to go ahead with its construction.

Downsville, N. Y.—Citizens of Downsville have subscribed a sufficient sum to cover the expense of surveying a line for an electric railroad to East Branch. A New York company is said to be satisfied that there is business enough to make a railroad to East Branch pay and is willing to consider the matter of building the road when surveys are submitted.

New Albany, Ind.—The Commercial Club of New Albany have about completed arrangements for the construction of the long-talked-of electric line from New Albany to Evansville, Ind. The line will extend along the river front between the two cities, taking in Corydon, Leavenworth, and in fact all of the river towns in Indiana between the terminal cities.

Akron, O.—The Akron, Bedford and Cleveland electric line started its first trains on October 30, and there is now an hourly service between the two terminals. The line is thirty-nine miles in length and has a roadbed equal to the bed of the ordinary steam line, so that the limit of speed may be reached. The scheduled time to the heart of Cleveland is one hour and a half.

Milford, Pa.—The building of an electric or steam railroad between Frenchtown and Pittstown, Huntingdon county, is talked of by the citizens of these two towns and the residents along the proposed road. Many of the property owners have already offered the right of way free through their properties and it is thought other property owners will do the same.

Bennington, Vt.—A preliminary survey for the electric road between Bennington and North Bennington is being made, and has been completed as far as North Bennington. It is intended to continue the survey as far as Walloomsac to connect with the line to Hoosick Falls. The work of constructing the road will be commenced early in the spring if present plans be carried out.

Brooklyn, N. Y.—The entire system of the Brooklyn Heights Railroad Company is now operated by electricity, steam on the Cypress Hill branch having been done away with. The electric cars on that line began running on the 5th inst.—A deal has been consummated between the Nassau Electric Railroad Company and the Brooklyn Traction Company, by which the former is to secure control of the latter.

Grand Rapids, Mich.—Grand Rapids will in a few weeks be connected with the Grand river and Flat river water power at Lowell by an electric line which will convey 500 horse power in electricity to this city. The power transmitted here will be used for lighting and for running motors, contracts for power up to 200 horse having already been made. The cost of the line from Lowell to this city approximates $450 a mile and the distance is 19½ miles.

Chattanooga, Tenn.—The master commissioner, Henry O. Ewing, advertises the sale of the Chattanooga Electric Railway by public auction on the 23d day of December next. The property will be sold subject to any rights which the bondholders of the Chattanooga Electric Street Railroad Company or the City Street Railroad Company may have by reason of certain trust deeds executed by the said two last named companies and entered of record in the register's office of Hamilton county, Tenn.

Youngstown, O.—A number of capitalists of Pittsburg, New Castle, and Beaver county, Pa., are organizing a company and will apply for a charter to construct an electric line from Pittsburg to New Castle. The new line will probably be a continuation of the line which is now being constructed on the east side of the Ohio river, and will run through Rochester, New Brighton and Beaver Falls and reach Youngstown via Enon Valley and Poland.

Logansport, Ind.—Eastern capitalists are interested in the construction of a new north and south electric street railway here, and it is announced that the system will probably be completed within the coming year. J. T. McNary, ex-manager of the present east and west line, will be the manager of the new company. If proper encouragement is given along the proposed route the system will be extended as rapidly as possible to Delphi via Camden and thence to Burlington by way of Flora and Bringhurst.

Lorain, O.—According to plans now under consideration, the East Lorain street railroad will be extended to Cleveland on an air line along the lake shore, a distance of 24 miles, connecting with Cleveland lines at Rocky River. The road will be used for both passengers and freight. Nearly all the right of way has been secured, and the commissioners of Cuyahoga and Lorain counties will be asked for a franchise in a few days. Mark Hanna, of Cleveland, is reported to be the financial head of the scheme.

Washington, D. C.—During a recent visit of Mr. Geo. Westinghouse, Jr., to this city, he stated to a "News" reporter, "that work on the new electric locomotives, now being constructed at the Baldwin Locomotive Works, Philadelphia, is progressing rapidly. These locomotives will be completed within a short time, when experimental trials will be made on the Pennsylvania railroad between New York and Philadelphia. It is expected that the electrical engines will be able to haul an ordinary train of coaches and maintain a speed of 120 miles per hour."—Lieut. N. E. Mason, the naval officer in charge of the proving grounds at Indian Head, Md., recommends that in the interests of economy and safety the quarters and buildings at the station be lighted by electricity. Oil lamps are now used.

Chicago.—It is stated that the franchises and property of the Englewood and Chicago Electric Railway Company and of the Chicago and Morgan Park Railway Company have passed into the control of a syndicate which includes August Belmont, John I. Waterbury, Isaac L. Rice, President Griscom of the International Navigation Company, J. C. Shaffer, of Chicago, and President W. W. Gibbs of the Electric Storage Battery Company of Philadelphia. It is proposed by this syndicate to construct a suburban electric railway system 100 miles long, using the "Chloride Accumulator" as motive power.

Niagara Falls, N. Y.—The Cliff Paper Company of this city has decided to do away with their steam engines and adopt electricity as a motive power. The generator will be placed in the gorge of the Niagara River, coupled to a horizontal shaft and water wheel operated under a head of 125 feet. The Cliff Company will immediately build a power house above their pulp mill in which will be placed the generator. A 250-horse power water wheel of the Leffel horizontal pattern has been ordered and will be ready as soon as the power house is finished. Two motors of 100-horse power will be attached to each of the paper machines.

Madison, Wis.—William T. Fish and H. C. Adams have secured a franchise from the town of Madison to build an electric railway line from Camp Randall to Wingra park, thence to Greenbush and from there back to this city, connecting with the present line near the Illinois Central depot.—Surveyors are at work on the line of the proposed electric railway from Chicago to the Wisconsin lakes and summer resorts. The route as being surveyed will start from the St. Paul Railroad at Libertyville, cross the Wisconsin Central at Gray's lake and run through the Fox lake region up to Wilmot, Wis., and probably to Lake Geneva and Madison.

Oakland, Cal.—It is the intention of the Pacific Transmission Company to put in a plant at Corrall Hollow for the generating of electric power to be transmitted by wire to San Jose and Oakland. The former place is to be supplied with 1,200 horse power and the latter with 3,800 horse power. The plant to be erected will be of the latest and best improved, regardless of cost. It will generate the power from refuse coal which would otherwise be waste material at the mine.—The Oakland "Enquirer" says: "The great economy of electric railroads as compared with cables is proved by the fact that the Southern Pacific finds it can save $2,900 a month by converting the San Pablo avenue road into an electric line. That is the result of investigation and computation recently made by the experts of the company, and the change will be made very soon now."

Milwaukee, Wis.—The special committee on street lighting has decided to report to the common council in favor of entering into a five years' contract with the Milwaukee Street Railway Company for the lighting of the city streets and public places with 2,000 candle power arc lights. A two-mile radius is to be established inside of which are to be only underground wires, and lights fed by such wires are to be paid for at a rate of $109 per lamp per year—a dollar less than what is now paid all over the city. Outside of this limit it is proposed to permit the stringing of overhead wires and in that district the rate is to be $92 per lamp per year.—The ten miles of subways for the cables of the Pabst Heat, Light & Power Company have been completed and the work of putting in the wires in the conduits is under way. The other work necessary to complete the new system is being pushed, and will be done by the time the cables are laid and connections made. New Willans engines, of English make, are to be put in and new Westinghouse generators, and the new plant will have a capacity of 50,000 lights as against 5,000, the capacity of the present plant. It will be run on the alternating instead of the direct system, with a pressure of 240 volts in place of 110 as at present. It is asserted that it will be one of the most complete plants of the character in the country.

TELEPHONE AND TELEGRAPH.

The Berliner an Extension of Blake's Patent.

To the Editor of ELECTRICITY.

SIR: There is one point in the transmitter situation which I have not seen raised. A patent was issued to Francis Blake. No one will deny that the Blake transmitter operated by variable pressure on electrodes which were intended to be in "constant contact." The Bell Company had the sole and undisputed use under this patent during its entire legal life, which is all that the patent laws anticipate that any patentee or assignee shall have. To claim under the Berliner that which was so long practically used under the Blake would be really an extension. Do the patent laws admit of extensions in this way?

A. BLAKE.

[If the Berliner patent is sustained in the court of last resort it will certainly mean, in this case at least, that the generally accepted interpretation of the meaning and intent of our patent laws has been an incorrect one. It will mean that practically a reissue of a valuable expiring patent can be secured if the matter is gone about in the right way.—ED.]

The Motion Denied.

The Supreme Court of the United States on the 11th inst. denied the motion of the Bell Telephone Company to dismiss the appeal of the United States in the Berliner case. The court holds that it has jurisdiction to try the case.

A Cable Up the Amazon.

Mr. Alexander Siemens, of London, is now engaged in surveying the route for the new cable about to be laid up the Amazon from Para to Manaos under exclusive concessions from the Government of the Brazilian Republic. The entire length is 1,365 nautical miles, and there will be in all sixteen stations on the line. This long sub-fluvial line will for the first time bring these regions, so increasingly productive of india-rubber, coffee and sugar, into direct telegraphic communication with Europe. All past attempts on the part of the Brazilian Government to establish aerial lines through these districts have failed, owing to the rapidity and density of the forest growths.

To Extend the Postal Lines.

Officials of the Postal Telegraph Company have been at Memphis, Tenn., looking over the prospect of extending the Postal's lines west of the Mississippi River through Arkansas and Texas. It is also thought they contemplate purchasing a line from Memphis to New Orleans operated by the Yazoo and Mississippi Valley Railroad.

The Longest Telephone Span.

The longest suspended telephone wire is no doubt that extending across Lake Wallenstadt, Switzerland. The distance from post to post measures one and a half miles, yet at the lowest point the wire is still 120 feet above the lake.

Litigation in the Northwest.

Papers have been filed in Milwaukee in the case of the National Telephone Construction Company against the Wisconsin Telephone Company in which it is sought to restrain the defendant from taking down a short telephone line in Waukesha and to prevent it from being disconnected with the long-distance service of the Wisconsin Company.

The subscribers of the Wisconsin Telephone Company at Milwaukee, who object so vigorously to the rates and rules recently enforced by the company, have formed an association for the purpose of "mutual action in seeking relief." Each subscriber is to contribute to a common fund which is to be used for the "purpose of investigating the workings of the telephone business and securing relief from burdensome charges and inefficient service."

The new exchange of the Wausau Telephone Company, Wausau, Wis., was opened last week with 121 subscribers. Service is supplied at $3 and $1.50 per month. To meet the rates, the Wisconsin Telephone Company announced a reduction to $1.25 and $1 per month.

The United Telegraph, Telephone & Electric Company, under a franchise granted to the Hyde Park Telegraph, Telephone & Electric Company in 1889, and purchased at a receiver's sale, is laying conduits and erecting pole lines in the streets of Hyde Park, Chicago. The company announces that it will establish a complete telegraph, telephone and messenger service.

The Automatic Telephone & Electric Company of Chicago has made an assignment to Frank C. Wood. The assets of the company are about $5,000 and the liabilities slightly exceed that amount. The company was organized about two months ago as the licensee for an automatic telephone for the State of Illinois outside of the city of Chicago. The company had not begun actual operations when it got into financial difficulties and finally concluded to make an assignment.

The manager of the Wisconsin Telephone Company at Oshkosh, Wis., has declared his company to be willing to furnish free service in that place if necessary to hold the business. The Oshkosh Telephone Company is about ready to open its new exchange, hence the desperate effort of the old company.

The Automatic Telephone Service Company, Buffalo, N. Y.—to provide for the use of the Strowger automatic telephone in that city. Capital stock, $300,000. Directors: Oliver Watson, Edward Mitchell, Henry Koons, Charles Eck and Tracy C. Becker, all of Buffalo.

The Lake Superior Telephone Company, which has already secured a franchise at West Superior, Minn., has applied for similar privileges at Duluth, Minn. John Goodnow, of Milwaukee, is identified with the new company.

The capital stock of the Southern New England Telephone Company is to be increased from $1,500,000 to $1,650,000. The increase is to be applied to improvements.

The Southwestern Telephone and Telegraph Company will extend its line from Waco to Houston, Tex.

The new telephone exchange with seventy-five subscribers is now in operation at Ocala, Fla.

The Delmaria Telephone Company is being organized at Wilmington, Del., with a capital stock of $250,000.

A fire alarm system is to be installed at Medina, N. Y.

New Companies Incorporated.

The People's Telephone and Telegraph Company, San Jose, Cal. Capital stock, $50,000. Directors: W. C. Andrews, Gus Lion, F. E. Spencer, H. G. Hickok, C. E. Severance, Nicholas Bowden, F. H. Burkholder, W. H. Field and Fred S. Moore.

The Western Telephone and Telegraph Company has been organized at Fort Wayne, Ind. The company is composed of local Lima, Ohio, capitalists. G. W. Beers is president and D. J. Cable, of Lima, is secretary. The company already controls telephone exchanges at Lima, St. Mary's Defiance, Van Wert and Wapakoneta, Ohio, and toll lines at many other points. It has options on lines at Decatur, Portland, Bluffton and Hartford City. Telegraph stations will be operated in connection with the telephone.

COMMERCIAL PARAGRAPHS.

Mr. J. M. Atkinson, already well known in the electrical trade, has been placed in charge of the Forest City Electric Company's Western office recently opened in Chicago.

W. D. Forbes & Company, 1300 Hudson street, Hoboken, N. J., are distributing an attractive circular calling attention to their high speed engines and other machine specialties.

The Siemens & Halske Electric Company, Chicago, has issued a series of catalogues devoted to Band Arc Lamps, Electric Rock Drills, Electric Motors, and other forms of apparatus. The books are profusely illustrated and contain considerable interesting and valuable data.

Fred M. Locke, Victor, N. Y., has issued an illustrated catalogue and price list of his well-known High Insulation Line Material. Supplementary to it he is publishing a long list of testimonial letters from people who have been using his goods.

The Ruete Conduit Company has established its general sales office in the Havemeyer Building, New York, with Mr. Frederick Noll, already well known to the electrical fraternity, in charge. The works of the company at 164 and 166 First street, Jersey City, are being fitted throughout with the latest types of labor-saving machinery, and within a few days the company will be able to take care of all orders. Mr. E. T. Greenfield, an interior conduit pioneer, and W. T. Ruete, whose name the company bears, will have personal supervision of the manufacturing department.

H. L. Merritt has become proprietor of the Boston Incandescent Lamp Company, and will continue the manufacture of the "Boston" lamp at 70 Pearl street, Boston.

INCORPORATIONS.

The Metropolitan Electric and Power Company, Allegan, Mich.—to do a general electric supply and water power business. Capital stock, $50,000. Promoters: John S. Rannay, Chicago, Ill.; F. A. Makin, Samuel Clark, Monterey, Mich.; Frank E. Semon, Allegan.

The Mexican National Exposition and Land Company, Jersey City, N. J.—to purchase, hold and improve lands, construct buildings thereon, establish electrical works, tramways, water works, etc. Capital stock, $1,000,000. Promoters: John P. Stockton, Trenton, N. J.; John R. Dos Passos, J. M. Ceballos, H. B. Hollins, New York City; C. N. Jordan, Brooklyn, N. Y.

The Camden Water, Light and Power Company, St. Louis, Mo—to deal in light, power and water. Capital stock, $50,000. Promoters: F. W. Paramore, E. E. Paramore, H. F. Mueller, Chas. Brown, St. Louis.

The Standard Brass and Electric Company, St. Paul, Minn.—to manufacture electrical and mechanical apparatus and supplies. Capital stock, $50,000. Promoters: Jehiel W. Jaggar, Jacob Heilbron, Theodore Guitting, St. Paul.

The Hafemeister Electric and Machine Company, Cleveland, Ohio—to manufacture machinery and electric goods. Capital stock, $5,000. Promoters: F. C. Hafemeister, G. C. Spaller, Henry F. Stolte, Wm. C. Hafemeister, E. F. Cowley.

The Nortonville Electric Light, Heat and Power Company, Nortonville, Kan.—to manufacture and supply light, heat and power to the public. Capital stock, $2,200. Promoters: John Campbell, John W. Harris, L. F. Randolph, C. C. McCarthy, Nortonville.

The Canton, Ohio, Light, Heat and Power Company has increased its capital stock from $50,000 to $150,000.

The Electric Light Company of Manitowoc, Wis, has filed an amendment to its articles increasing its capital stock from $40,000 to $50,000.

The Western Electric Transit and Power Company, Boulder, Col.—to construct electric plants, railway lines, carry on a general business of an electric transit company, etc. Capital stock, 100,000. Incorporators and directors: E. B. Goodwin, W. K. Mehollin, Oliver I. Cheney, John Leahy, A. J. Macky, H. J. Danford, Bernard Mallon and Frank Kline.

The Oakdale Electric Light, Heat and Power Company, Oakdale, Pa. Capital stock, $8,000. Directors: John C. Bryson, Ebenezer A. Thompson, Samuel E. McClurg, Harry D. Robb, Samuel D. Bryson, Oakdale.

The Hyde Park Thomson-Houston Light Company, Chicago, has increased its capital stock from $100,000 to $125,000.

The Newton Traction Company, Jersey City, N. J—to contract for, build and construct street railways, electric railways, electric power and light systems, etc. Capital stock, $1,000,000. Promoters: Horace B. Parker, Newton, Mass.; Louis Pfingst, Boston, Mass.; Frank P. Hillyer, New York City; John N. Baldwin, Council Bluffs, Iowa.

The Acetylene Electric Gas Company (incorporated in W. Va.), Philadelphia, Pa.—to manufacture calcium, carbide and other metallic compounds and liquifying acetylene gas, etc. Capital stock, $1,000 minimum, $1,000,000 maximum. Promoters: I. D. McKee, Jos. Cooper, Wm. T. Emerson, Edw. P. Carpenter, Philadelphia, Pa.

The Fulton Street Railroad Company, New York City (re-organization of the North and East River Railroad Company). Capital stock, $500,000. Promoters: J. H. O'Rourke, A. H. Smith, Wm. Farrell, John Bray, J. J. Mahoney, Brooklyn, N. Y.

The Los Angeles Petroleum Smelting and Milling Company, Los Angeles, Cal.—to buy and sell mineral and other lands; build and operate smelting works; buy and construct railroads, telephone lines and electric light systems. Capital stock, $200,000. Promoters: J. H Canavan, E. M. Wade, E. J. Reed, J. H. Bryant, Los Angeles; S. J. Keese, Pasadena, Cal.

The Dunmore Street Railway Company, Scranton, Pa. to build an electric street railway. Capital stock, $30,000. Promoters: Frank Silliman, Jr., Horace E. Hand, Robt. F. Fox, Scranton, Pa.

The Waddell-Entz Machine Company (incorporated in W. Va.), New York City—to purchase, sell, etc., electric apparatus and machinery, etc. Capital stock, $50,000. Promoters: Alfred A. Whitman, New York City; Jose A. Machado, Plainfield, N. J.; Antonio Knauth, New York City

The Washington Light, Heat and Power Company, Washington, N. J.—to generate electricity for light, heat and power. Capital stock, 24,000. Promoters: Jno. Karr, Hackettstown, N. J.; Wm. A. Stryker, Frank P. McKinstry, John W. Fitts, Joseph W. Johnson, Washington.

The Mount Lowe Railway Company, Pasadena, Cal.—to construct, lease and operate electric and other railroads; operate telephone and telegraph lines, water and electric lighting and power plants. Capital stock, $1,000,000. Promoters: Thaddeus S. C. Lowe, Leon P. Lowe, Herbert C. Brown, Sobieski Lowe, Pasadena; Thaddeus Lowe, Altadena, Cal.

The Pasadena and Altadena Railway Company, Pasadena, Cal.—to construct an electric railway and operate same by electricity or stationary or locomotive gas or steam engines or wire cables. Capital stock, $100,000. Promoters: Leon P. Lowe, Thaddeus S. C. Lowe, Thaddeus Lowe, L. A. Lowe, Herbert C. Prown, Pasadena.

The Reed Electric Company, Philadelphia, Pa.—to manufacture electrical and mechanical appliances and apparatus. Capital stock, $500,000. Promoters: Amos W. Bacon, Carl Hering, Philadelphia; Marcellus T. Morrill, Camden, N. J.

The Osborn Electro Magnetic Railway System (incorporated in W. Va.), Auburn, N.Y—to manufacture apparatus for transmitting electro-motor cars, and all appliances pertaining to electric railway equipment, etc. Capital stock, $30,000 minimum; $1,0 0,000 maximum. Promoters: Byron E. Osborn, J. Harrison-Pearson, Ruth E. Osborn, A. J. Parker, Auburn, N. Y.; Chas. Thompson, New York City.

The Standard Electric Storage Battery Company (incorporated in W. Va.), New York, N.Y.—to own, lease and sell electrical appliances, batteries, etc.; electrical contractors, manufacturers, etc. Capital stock, $1,000 minimum, $5,000,000 maximum. Promoters: Ernest Thalman, R. T. Mc Donald, James Marwick, W. H. Bankier, New York City.

The Scott & Janney Electric & Manufacturing Co. (incorporated in W. Va.), Philadelphia, Pa.—to manufacture and construct electrical motors, dynamos, etc. Capital stock, $5,000 minimum, $5,000,000 maximum. Promoters: Dudley W. Lane, Geo. W. Edmunds, Chas. Watson, Geo. H. Hill, Philadelphia, Pa.

The International Electric Company (incorporated in W. Va.), New York, N. Y.—to manufacture motors, dynamos and all kinds of electrical apparatus, etc. Capital stock, $10,000 minimum, $2,000,000 maximum. Promoters: Jno. H. Hankins, Steubenville, Ohio; G. M. Rundle, Danbury, Conn.; G. V. P. Lansing, Seattle, Wash.

BUSINESS HINTS.

Public Buildings, Theaters, Residences, &c., Proposed or in Course of Construction.

[The following summary is prepared weekly for ELECTRICITY for the information of advertisers and readers who are dealers in apparatus and, articles required in the electrical equipment of public and private buildings.]

Albany, N. Y.—The Albany Insurance Co. will erect a building on the Gladding property, adjoining the Albany Savings Bank.

Allentown, Pa.—Philip Schneider, shoe manufacturer, will build a factory on Jefferson and Pine sts.; the motive power of the new factory will in all probability be electricity.

Baltimore, Md.—The Baltimore Athletic Club is considering the question of erecting a club-house, to cost $60,000; Dr. B. Merrill Hopkinson is president of the club.

Beaver Falls, Pa.—An option has been secured by Pittsburg parties of a large plot of ground at Beaver upon which they propose to erect a magnificent hotel if the Masonic University is built; estimated cost, $500,000.

Brooklyn, N. Y.—E. R. Barteaux will build 3 four story brick dwellings on north side of Montgomery Place, east of 8th ave., to cost $57,000.

New York City.—Henry & Hartmann Schmidt, 112 East 129th st., will build 2 five story flats, on north side of 119th st., east of Madison ave.; Architect Edward Wenz, 205 East 84th st.... John Nold, 429 West 48th st., will build a five story flat and store on east side of Amsterdam ave., south of 100th st., to cost $17,000; Architect George F. Pelham, 503 5th ave.... Francis A. Clark, 1879 Second ave., will build 8 five story and extension brick stores and flats of various dimensions on west side of 1st ave., between 95th and 96th sts.; Architect Edward Wenz, 205 East 84th st.... Dora Bernschild, 1026 Westchester ave, will build a five story tenement and store south side of Westchester ave., east of Union ave.... Wm. W. & Thomas M. Hall, 687 Madison ave., will build 9 four story dwellings of various dimensions on north side of 87th st., east of Riverside Drive; Architect A. M. Walsh.... Curming & Ferguson have purchased a plot on the east side of Amsterdam ave., north of 106th st, and plot on Amsterdam ave., south of 108th st., upon which they will erect five story flats and stores.

Paterson, N. J.—The building which is to be erected by Quackenbush & Co. on Main st. will be equipped with electrical appliances.

Philadelphia, Pa.—Work will be begun in a short time, renovating St. Augustine's Roman Catholic Church, 4th, below Vine st.; among the new features to be introduced are electric lights in place of gas.... Preliminary sketches have been prepared by Architect Henry D. Dagit for the elevation and details for a large ten story office building to be built by the Pennsylvania Mutual Life Insurance Co.... The dwellings, twelve in number, which Wright & Prenzel will erect on west side of Germantown ave., above Broad st., will be lighted by electricity.... The Philopatrian Literary Institute has adopted plans prepared by Yarnell & Goforth for its new building, which is to be erected on the site of the present one, on 12th st., below Walnut; the structure will contain a library, reading room, reception parlors, conversation rooms, offices for the officers of the institute and gymnasium on the upper floors, a culinary department, bath and a swimming pool in the basement.

Pittsburg, Pa.—C. L. Flaccus, the glass manufacturer, has broken ground for a residence at the intersection of Negley, Stratford and Roup sts., to be equipped with all modern improvements.... Architect W. S. Fraser has completed plans for a six story fireproof building on Penn ave. above 9th st., for Charles Lockhart.... Chess & Hall will erect a six story business house on 10th st.

Rahway, N. J.—Mr. Rothschild, who is to establish a shirt factory in Rahway, will probably introduce electric motors to run the sewing machines.

St. Paul, Minn—The plans prepared by Cass Gilbert have been accepted for the Minnesota State capitol.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 5, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

549,094. Brake for Electric or Other Cars. Edward S. Amrock, Waltham, assignor of one-half to James H Walsh, Boston, Mass. Filed March 16, 1892.

549,256. Fender Attachment for Trolley-Cars. Henry F. Risch, Brooklyn, N. Y. Filed Aug. 4, 1894.

549,416. Insulating Rails. Francis W. Wilson, New York, N. Y. Filed June 22, 1895.

ELECTRIC LIGHTS AND APPLIANCES.

549,132. Electric-Arc Lamp. Francis Jehl, Vienna, Austria-Hungary, assignor to F. Hardtmuth & Co, same place. Filed May 12, 1894.

549,201. Incandescent-Lamp Reflector. Charles J. Klein, New York, N. Y. Filed April 18, 1895.

549,268. Arc Cut-Out. Caryl D. Haskins, Newton, Mass., assignor to the General Electric Company of New York. Filed March 6, 1895.

549,409. Electric-Arc Lamp. Charles F. Vogelius, Bloomfield, N. J., assignor to Joshua F. Bailey, New York, N. Y. Filed Jan. 17, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

549,153. Controlling Electric Motors. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 8, 1895.

549,162. Electric Switch. Joseph B. Smith and Albert L. Clough, Manchester, N. H. Filed April 26, 1895.

549,189. System of Electrical Distribution. William M Fairfax, Brooklyn, N. Y. Filed Feb. 7, 1893.

549,209. Electromagnetic Switch. Charles L. Penny, Newark, Del. Filed March 12, 1895.

549,234. Armature for Dynamo-Electric Machines or Motors. Ward Decker, Owego, N. Y. Filed Nov. 17, 1892.

549,237. Electric Switch. Gerald W. Hart, Hartford, Conn., assignor to the Hart & Hegeman Manufacturing Company, same place. Filed March 19, 1895.

549,383. Automatic Regulator for Converters of Energy. William E. Moore, Augusta, Ga. Filed March 20, 1895.

549,456. Carbon-Contact-Resistance Switch. Friederick G. H. Meyer, Charlottenburg, Germany, assignor, by mesne assignments to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed April 4, 1894.

549,461. Electrical Dental Engine. Frank C. Priestly, Denver, Colo. Filed Feb. 12, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

549,179. Printing-Telegraph System. Jonathan E. Woodbridge, Duluth, Minn. Filed Jan. 29, 1895.

549,304. Telephone. Samuel Alexander, Hartford, Conn. Filed Sept. 24, 1895.

549,477. Local Transmitter-Circuit for Telephones. William W. Dean, St. Louis, Mo., assignor to the Bell Telephone Company of Missouri, same place. Filed March 29, 1895.

MISCELLANEOUS.

549,152. Electric Heater for Curling-Irons. George D. Pogue, Jerseyville, Ill. Filed March 29, 1895.

549,186. Electrolytic Apparatus. Thomas Craney, Bay City, Mich. Filed March 16, 1893.

549,195. Electric Meter. Ralph O. Hood, Danvers, Mass. Filed March 9, 1895.

549,240. Electrical Annunciator. Robert L. Hunter, Minneapolis, Minn. Filed Dec. 11, 1893.

549,241. Electrical Annunciator. Robert L. Hunter, Minneapolis, Minn. Filed Feb. 3, 1894.

549,254. Method of Making Insulator-Rings. Charles F. Peterson, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed June 1, 1895.

549,346. Transmitting-Time-Signals. Charles E. Buell, North Plainfield, N. J. Filed May 27, 1895.

549,443. Electric Supporting-Insulator. Joseph Collins, Washington, D. C. Filed Sept. 23, 1895.

549,470. Electrical Resistance. Henry E. Werline, Lancaster, Pa., assignor of three-fourths to Frank S. Barr, same place, and Edwin L. Reinhold and Henry Burd Cassel, Marietta, Pa. Filed Dec. 23, 1895.

ELECTRICITY.

Vol. IX. NEW YORK, NOVEMBER 20, 1895. No. 19

ELECTRICITY

Published every Wednesday by the
ELECTRICITY NEWSPAPER CO.
B. E. GREENE, President.
L. J. MONTGOMERY, Secretary.

Publication Office, - - 6 Park Place, New York.

Editors: BURTON E. GREENE.
R. H. WILLOUGHBY.

Business Manager, - - - JOHN L. GANS.

SUBSCRIPTION RATES:

United States, - - - - - - - - - $2.50
In Clubs of Five or More, - - - - - - - 2.00
Foreign Countries, - - - - - - - - 4.50
Single Copies, - - - - - - - - - 10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

American vs. English Progress. No one who has been abroad recently, or who reads the English technical papers, can fail to note that in electric traction work America is far in advance of the parent country. Nothing shows more plainly the difference between the character and forces of the two nations than a comparison of their progress in this line. Electric railroads of various kinds have become so common in America that a new line with 25, 50, or 100 miles of track creates little comment. Not so in England. At the opening of every new line, however small, there is a public function at which some of the leading dignitaries of the Empire are expected to preside, and several pages of the best technical papers are devoted to descriptions and illustrations which must be interesting to English readers (else they would not be printed), but which would be considered commonplace and stale by the American public.

Knowing that this sort of thing was looked for in the English press, our London correspondent (who is, by the way, one of the brightest newspaper men in London) recently sent us for publication a long description of one of these events, beginning as follows:

"On Monday, October 14th, there was publicly opened a new line of electric tramways on the overhead trolley system, running between Kingswood and Bristol, two West of England towns, a distance of nearly four miles."

He also reported:

"The journey of about four miles occupied about thirty minutes, but it must be borne in mind that red tape will not allow us to run our cars at more than about eight miles an hour in England, therefore that is no index to the capacity of the cars. On the return journey the party stopped at the power house, which is about half way down the line, to inspect the machinery there, and afterwards adjourned to partake of the usual banquet."

Commenting on the slowness of the British public in going ahead with traction work, he says:

"In one respect our slowness to adopt electric traction over here is a distinct advantage, inasmuch as now that there are evidences of an extensive revival of the business and important schemes are in progress, while various others are in the air, we are enabled to make use of the past and dearly purchased experiences and the conclusions deduced therefrom by electric traction pioneers in the United States. We have far more light to guide us in the choice of systems and the various details of apparatus, as to what is the more suitable and so forth, than you had in the States when you laid down your first important traction schemes. It may thus be expected that all our systems which are now in progress will be in every way successful and satisfactory."

Of course there is more than a little common sense in this view of the case: Millions of capital were lost here in establishing successful electric railways, and it is a purely American characteristic that so much money can always be had here for experimental work when the looked-for success appears to justify the expenditure. From the narrow point of view of the capitalist, we have no doubt Englishmen showed good judgment in waiting for America to blaze the way. But from the broader standpoint, considering the greatest good to the greatest number, America has no mistakes of judgment to confess. As early as 1890 or 1891, millions of American workingmen were giving thanks for the introduction of trolley roads, giving them the opportunity of living cleanly and wholesomely in suburban districts—something never before attainable. This number has been increased every year.

Moreover, from recent reports we are not willing to admit that English construction of electric railways is better than our own. Certain it is that although several years behind us in the lighting field, we have maintained our superiority at every point—if we except the application of the gas engine and the accumulator adjuncts. The great American public does not regret the ardor and enthusiasm with which the electric railway business was pushed here. The rooster crows.

If we have paid for the education of our British friends, we are a philanthropic people, and will continue to lead the world and teach progress.

* * *

Electricity and Sewage. The decomposition of sea water by electrolysis, and the application of the chlorine thus obtained to the disinfection of sewage has, wherever tried, demonstrated not only the complete practicability of the method but its economy, commercially considered.

Prof. John W. Langley, of the Case School of Applied Science, Cleveland, Ohio, who has given considerable attention to this problem by investigation and experiment, states some interesting facts in his address elsewhere published in this issue. To those interested in the problem of the cheap and effective purification of sewage, the data deduced from Prof. Langley's experiments will be of considerable value. Although the operating plant used by Prof. Langley was of a capacity totally inadequate to the needs of a large city, the results attained show that from the expenditure of one electrical horse power per hour 6.37 pounds of chlorine can be produced.

"The quantity," Professor Langley says, "would purify over fourteen thousand gallons of sewage per day of ten hours. A hundred horse-power would therefore disinfect nearly a million and a half gallons in the same time. The cost of the process will be but little more than the cost of electricity plus that of pumping the sea water and the small additional amount for wages. These can be approximately estimated at twenty-five cents for 1,400 gallons when carried out on a scale of 500 horse-power. Taking the wholesale price of bleaching powder, its cost to do the same amount of disinfection would be at least twenty times as great. For inland cities the cost of salt would have to be added, but even then the expense would still be much below that of bleaching powder."

The economy and simplicity of this method would, it seems, indicate its general application in the near future.

* * *

Russell Sage and Stockjobbing Trusts. One would as little expect a discourse from Dr. Chauncey M. Depew on "The Vanity of Flattery" as a dissertation by Mr. Charles A. Coffin on "The Evils of Bonding." Treated by the authors, these subjects would be as incongruous in the literature of post-prandial and business life as the subjects themselves are foreign to the habits, tastes, inclinations and achievements of the distinguished gentlemen named. Scarcely less surprising would it be to learn that Russell Sage, the multi-millionaire, has become the author of what may properly be termed a treatise on the "Wickedness of Trusts."

Mr. Sage, it may truthfully be said, has more than a speaking acquaintance with Wall Street. There have been days in his eventful career when he was on the wrong side of the market, but he hasn't stayed there long. By the aid of the experience of years, a highly-developed Shylockian instinct, and a careful perusal of ELECTRICITY, he has discovered that the annual reports of stockjobbing companies, like dynamite bombs, are not always what they seem. The process by which vanishing assets are converted into tangible, or a deficit into a profit, like some of the processes of nature and of science, are known only by the results accomplished, or by the phenomena exhibited.

Yet, notwithstanding Mr. Sage has learned that the stock of companies which one day sells at 34, on another at 29¼ and on another at 30¾, is actually worth but about $4 a share, and not a particularly safe investment at that. For aught the public knows, it may have been the discovery of this and similar facts that prompted him to exclaim, more in anger than in sorrow:

> The public, or rather stock and bond holders and dealers in the certificates and bonds of these corporations, should be enabled to know what the companies are doing. Regular reports should be forced from them. They should not be allowed to run as blind pools, over-capitalized, watered, mismanaged by the cliques in control, over whose actions the stockholders really have no power.

It is to be regretted that Mr. Sage has neglected to be specific in his remarks, omitting, as he has done, to name the particular stocks to which the designations "blind pool," "over-capitalized," "watered," "mismanaged," etc., are applied. To have enumerated this class of insecurities would have added much strength to another observation he made anent this subject:

> It is all very well to say that nobody is forced to invest in these concerns, but the securities are put out through the regular channels and powerful influences are willing to induce the public to come in with its money. There is no valid excuse for secrecy on the ground that the independent trade otherwise would learn about inside business. Whatever cannot stand up under open competition has something wrong with it.

* * *

The Farmer Patents. The announcement that a number of patents issued to the late Moses G. Farmer are now offered for sale will create considerable interest. Mr. Farmer was one of the earlier pioneers, a prolific inventor, and one who did much good work. Although partially paralyzed for some time before his death, his mind was clear and bright, and he was active to the last in originating new devices and improvements on some of his earlier products.

It is more than possible that some of the new telephone companies will find in these Farmer patents just what they need to insure a successful business and as a protection against patent litigation.

Under the Searchlight.

Views and Opinions on Timely Topics.

By those best posted, the rumor that Mr. Coffin has resigned from the General Electric Company is regarded as sheer nonsense. It is stated by those who know, that Mr. Coffin will never be forced out. When he retires if at all, it will be voluntarily.

Mr. Coffin still has confidence in his star, and believes he can yet pull the General Electric Company out of all its difficulties.

We are authorized to announce that Mr. Coffin is not a quitter.

* * *

A Western View of the Standard Telephone Company.

(From the Pacific Electrician.)

When the Standard Telephone Company was organized in the East it was stated that it had unlimited millions back of it, that it had secured valuable patents, and was prepared to push the telephone business in all parts of the United States.

It has had its agents out in different parts of the country endeavoring to form local companies to sell *rights* (?) and has talked about starting factories in various localities. Lately there has been considerable inquiry from different quarters as to the purpose and standing of this company, and until recently no satisfactory answer could be given. ELECTRICITY seems to have got at the true inwardness of the concern.

The Standard Company has no factory, it has no rights, and it is evidently running a skin game. A concern that will calmly advise the commission of a felony will be pretty sure to swindle its own licensees

* * *

This Man Is a Fraud.

(Aberdeen [Miss.] Special in New Orleans Picayune.)

At a meeting of the Board of Aldermen a contract was awarded for lighting the town by electricity to Thompson Houston.

Mr. Coffin Resigns

Continued Friction in the United Electric Securities Company.

As a result of the three-cornered fight between the General Electric Company, the United Electric Securities Company and the Ft. Wayne Electric Corporation, Mr. Charles A. Coffin handed in his resignation as a director in the United Electric Securities Company of Boston last week.

The resignation has not yet been acted upon.

The General Electric Company holds all the common stock of the Securities Company—$500,000. There is $1,000,000 preferred stock widely scattered. At this year's annual meeting, early in September, Mr. Coffin appeared with proxies enough to give him about 100 majority. The opposition threatened to make the controversy public through circulars, and the meeting was adjourned without action.

Mr. Coffin's contention was that Messrs. Pevear, Allston Burr and Perry be ousted from their official positions. This was an impossible concession on the part of the honest investors who believe, and properly so, that these three gentlemen are looking out for the best interests of the Securities Company regardless of entanglements with any manufacturing company.

Since September 10 there have been several meetings of Securities Company stockholders; all adjourned without action.

The present holdover officers of the Securities Company are: Samuel Carr, President; Arthur Perry, Vice-President; Allston Burr, Treasurer. Directors: Oliver Ames, Allston Burr, Isaac T. Burr, Samuel Carr, C. A. Coffin, Robert Treat Paine, 2d, Francis Peabody, Jr., Arthur Perry, H. A. Pevear.

A Submerged Electric Railway.

(From our London Correspondent.)

An interesting electric railway is now in course of construction along the coast between Brighton and Rottingdean, on the southeastern coast of England. The line is intended purely for pleasure purposes. It is questionable whether the novelties and peculiarities of this line are to be met with in any other part of the world.

The coast is bold, practically the whole distance having chalk cliffs varying from 60 to 120 feet in height. The rails being laid a considerable distance from the shore, a fine view of the coast is obtained.

The rails are laid on concrete block (made *in situ*), spaced about 3 feet apart, mortised into the sound rock, the height of the blocks varying with the irregularities of the shore; a shifting sand of very moderate depth covers the rocks in places; the track, however, has been laid sufficiently high to prevent any trouble from accumulations on the rails. The steepest gradient is 1 to 300 and the radius of curves 40 chains. The line consists of four rails (54 lbs. per yard) laid as two tracks of 2′ 8½″ gauge, spaced about 18 feet between outer rails, thus giving a gauge of 18 feet, this being rendered necessary to give the required stability to the cars. The rails are secured by steel clips and bolts, the latter being embedded in concrete, oak blocks, through which the bolts pass, being placed between the rails and the concrete blocks. Tie rods are also used every 10 feet on the straight and every five feet on the curves, heavy angle fish-plates being used for the rail joints.

The depth of water over the rails at high tide is 15 feet. Although the most violent gales experienced for many years occurred during the winter of 1894-5, no damage whatever was done to the permanent way, so the fact that it possesses ample strength to resist the force of the sea has been satisfactorily demonstrated, and no accumulation of sea weed, etc., has taken place at any time.

The car is a structure on 16 wheels, 33 inches in diameter, carrying the passengers at a height of 24 feet above the level of the rails; the four main legs are tubes of drawn steel 11 inches in diameter. At the bottom of each leg is placed a bogie truck having four wheels, the outside of the bogie being shaped like an inverted double-ended boat to facilitate its passage through the water, and also to remove any obstructions from the rails. The four bogies are firmly held together by steel tubular struts. The wheel base is about 28 feet and the effective gauge 18 feet, giving great stability. The tops of the main legs are firmly built into lattice girder work carrying the deck, and the whole structure is firmly secured by cross ties and is of great strength although offering but a small surface to the force of the waves.

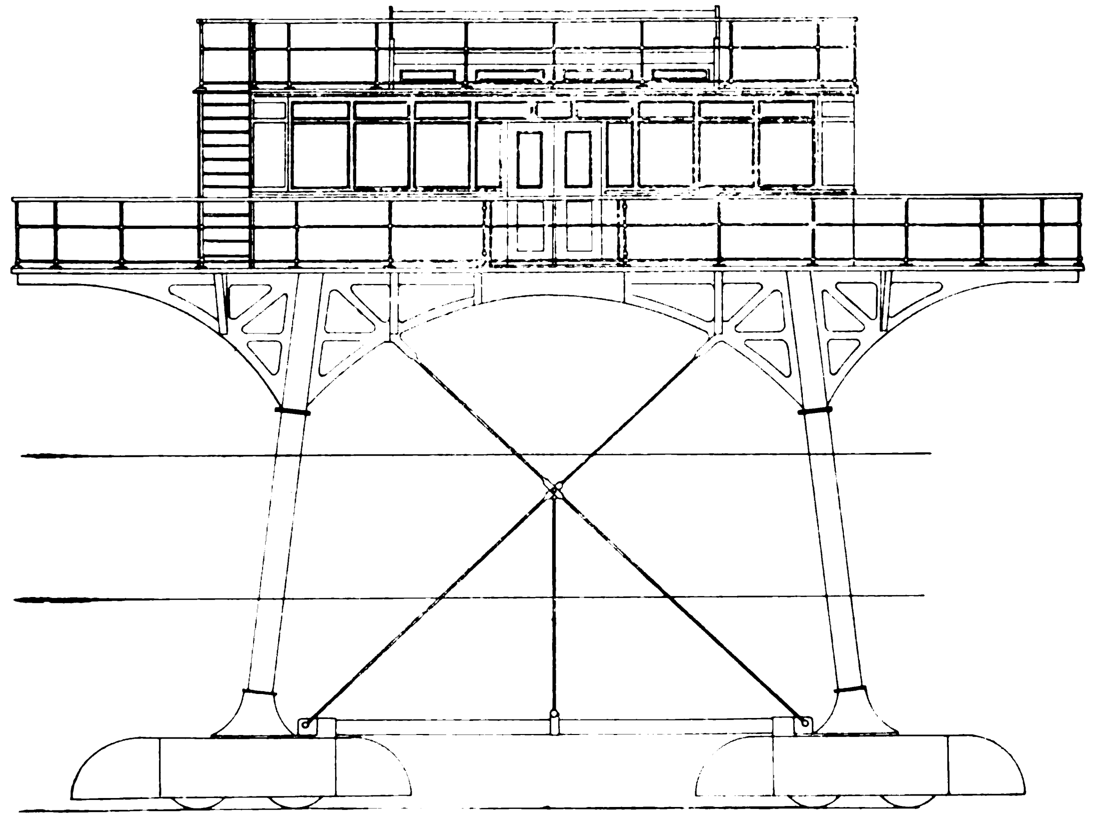
The main deck appurtenances and erections are carried out exactly as if for a yacht; the deck measures 50 feet long and 22 feet wide, the railings round the deck being of iron with a wooden top rail and wire netting. Seats with reversible backs are provided. The center space of the deck is occupied by the saloon, a structure 12 feet wide by 25 feet long, provided with plate glass windows all round and a large central ottoman. The center of the ceiling is occupied by a stained glass dome. The roof of the saloon is railed round and forms a promenade deck, and on this upper deck are placed the controlling apparatus for driving and stopping the cars. The total accommodation is for 100 to 150 passengers. As the journey will be undertaken more for the sea air than for quickly making the trip, the speed will be kept between six and eight miles an hour.

The driving machinery consists of two 30 H. P. electric motors placed vertically immediately over *two of* the main legs, one on each side of the car, the shafting being carried down inside and communicating with toothed gearing which actuates the wheels. The brakes are worked by rods passing down the remaining two legs. The current at 500 volts will be conveyed to the car by means of a trolley pole and overhead wire, provided the consent of the corporation of Brighton be obtained for the portion within the borough.

It was originally intended that accumulators should supply the motive power, but it has since been considered that to make the undertaking a commercial success current should be carried by wires, poles being laid along the foreshore for this purpose. The weight of the accumulators necessary was found to be equal to that of about 60 passengers, a consideration which weighed largely with the promoters in deciding.

The total cost is said to be only $100,000 and the system is to be worked by the company, who have laid it without the assistance of contractors.

Mr. St. George Moore is engineer, in conjunction with Mr. Magnus Volk, whose name has been associated with the Brighton Electric Railway for the past ten years or more, and who is really the promoter of the present undertaking and will supervise its construction. It should be mentioned that it was with Mr. Volk that the idea of running a self-propelling car on a railway submerged in the sea originated.



ELEVATION OF CAR—SUBMERGED ELECTRIC RAILWAY.

DR. CUSHMAN'S LECTURES ON THE TELEPHONE.

ABSTRACTED BY JOHN S. BIGGAR.

The expiration of Bell's 1876 and 1877 patents does not affect Cushman's 1851 claims now pending. Bell's 1876 and 1877 patents covered broadly, as stated by the Supreme Court's decisions, two methods of electrically transmitting and receiving speech. One method was by passing through a circuit, then occupied by a current, a second current, making use of articulate speech in the creation of this last current. The apparatus used by Bell, as described in his patent, to produce this second current, was the same as the receiver now commonly used.

The other method patented by Bell was increasing and diminishing the transmitting current by increasing and diminishing the resistance of the circuit through which the current passed. The apparatus used in this method operated upon the principle of variable pressure between electrodes, the variations being produced by the vibrations impinged upon the transmitting device when it was spoken into.

Cushman invented such apparatus in 1851. In 1868 George B. Hicks improved Cushman's instrument o 1851 by employing a loose connection in a local circuit, using coke in its construction. Morse invented and patented a method of placing in a circuit a variable contact, the pressure of which could be regulated by the hand so as to increase the sound at the receiver.

The Bell Company have proven, and the courts have decided, that a microphone carbon transmitter is the equivalent of Bell's magneto-transmitter. A large number of suits have been brought by the Bell Company against parties making, using and vending telephones employing battery transmitters, and in every case where decisions have been reached the courts have held such infringing transmitters to be the same as the apparatus, and operating by the same method as set forth in the patents granted to Bell in 1876 and 1877. Over one hundred patents upon transmitters have issued since 1876, to live only till the courts could say: "Begone, you are an equivalent of Bell's 1876 and 1877 patents. These patents to Bell are not dead. They live. They have been made strong by litigation.

In regard to the 1876 patent the Supreme Court says: "The patent is for the apparatus described or its equivalent." Any apparatus, then, that will increase and diminish the resistance of the circuit in the manner described so as to vary the current will infringe the apparatus constructed under the patent of 1876. The Berliner patent of 1891 is the same patent of 1876 under a different name. On March 4, 1895, the Supreme Court unanimously decided that the date of a United States patent, not the application, controls in determining the life of a foreign patent. This decision sounds the death knell of the American Bell Telephone Company's chief reliance.

The Berliner patent is void and has been once so decided. It is void because anticipated by Bell in 1876 and others since then. If valid at all Berliner's patent must be confined to mechanical construction, combination and design. He must combine those particular parts, so designed and shaped. He cannot combine old parts that produce old results.

Berliner stands in the same relation to the Bell patents of 1876 and 1877 as Jones stood to a patent issued to Smith. Smith obtained a patent on a machine for killing ducks. He combined a man, a gun and a dog, which made his machine; Jones combined a woman, a gun and a dog, which combination constituted his invention. The courts held Jones's patent to be void because the mere change of words, or a slight variation, did not constitute an invention.

DYNAMOMETER FOR STREET CARS.

A dynamometer car is to be used on the Chicago City Railway for track inspection. The idea originated with Superintendent M. K. Bowen.

Mr. Bowen's scheme is to register the dynamometer curve in dollars and cents so that a glance at the map will tell the total cost to the company in pulling a car over any part of the track.

Personal.

Mr. W. D. Packard, secretary and treasurer of the Packrad Electric Company, Warren, Ohio, was an Eastern visitor last week.

G. E. EXPLOITING WORK.

OBJECT LESSONS—THE CHARACTER OF ESTABLISHED STATIONS.

Samples of the Facilities Afforded to Local Enterprises.

[The Edison Company, to a small extent, and the T.-H. Company (the organization of which was mainly adopted by your company), to a greater extent, had been in the habit of doing more or less exploiting work, resulting in the acquisition of stocks and bonds of local lighting and railway companies. By the facilities which it had thus been able to afford to local enterprises it was enabled to expand its business.—*G. E. Company's Annual Report, 1894.*]

CHAPTER II.

TRIALS AND TRIBULATIONS OF A G. E. CENTRAL STATION MANAGER.

Reports of the Superintendent of the Austin (Minn.) Station.

Austin, Minn., Aug. 27, 1893.

C. R. Hyde.

Dear Sir: I have been trying some of these lamps with adapters, and find they are wholly unfit for any place. These adapters fit the lamp base so tightly that you cannot make contact with the pole piece of the adapter and the pole piece of the lamp. Only about one out of ten will work, so you see that I can do but little with these goods. Yours very truly,

W. S. PIERCE.

Austin, Minn., Sept. 13, 1893.

Geo. C. Duffie.

Dear Sir: Inclosed please find statement of the 2 cars of coal ordered the 2d day of August, not the last two cars. There are two cars on the track, just in, on which I paid the freight charges this morning with my personal check, amounting to $80.00. Please send check for this amount payable to either Arthur Cole, or as usual, and he will endorse and give to me, so I can get my money back. Yours truly,

W. S. PIERCE.

Robinson & Cary Company,
Railway, Mill and Miners' Supplies, Engines,
Boilers, Machinery, etc.
St. Paul, Minn., Sept. 21, 1893.

Austin Electric Light & Power Co.,
Austin, Minn.

Gentlemen: Kindly hand us payment $6.60, the amount of your invoice of July 17th last, so that the same may reach us not later than the 25th inst., and greatly oblige yours truly,

ROBINSON & CARY COMPANY,
By S. M. CARY.

Austin Electric Company.
Austin, Minn., Sept. 22, 1893.

C. R. Hyde.

Dear Sir: Please ship us 50 lbs. waste and 100 lbs. boiler compound. We can not keep our boilers from scaling with the kerosene. Yours truly,

W. S. PIERCE.

Austin Electric Company.
Geo. C. Duffie, Treasurer.
W. S. Pierce, Manager.
Austin, Minn., Sep. 29, 1893.

C. R. Hyde.

Dear Sir: Enclosed please find bills of time, for which please send check. I will see that enough has been collected to pay these checks before I give them to the parties. Yours truly,

W. S. PIERCE.

Austin, Minn., Oct. 13, 1893.

C. R. Hyde.

Dear Sir: I have been absent on a trip to the World's Fair, and returned this morning. I have before me a letter from R. G. Tobey, requesting me to send him the monthly reports of this station for the months of July and August. This is the first knowledge I have had that I was to send duplicates each month to the Boston office. Very truly yours,

W. S. PIERCE.

Austin, Minn., Oct. 18, 1893.

C. R. Hyde.

Dear Sir: We are low on carbons. Please ship at once 2,000 $\frac{7}{16}$″ plain carbons. Don't ship the T. & H. such as we had which caused so much trouble, but send the "National" if possible. The boys worked me on those tips or half carbons, because they are simply those poor carbons broken off.

Yours very truly, W. S. PIERCE.

Austin, Minn., October 23, 1893.

C. R. Hyde.

Dear Sir: I send you receipt for freight paid by myself on four cars of coal. Please send me check for the $160 and oblige, or make the check payable

to Arthur Cole and he can endorse and give to me.
Very truly yours,
W. S. PIERCE.

Austin, Minn., November 1, 1893.
Austin Electric Company, Dr.
To Barney Farrington.
Salary as first engineer for the month of October 1893.. $60.00

[It is evident from the above that Mr. Barney Farrington got his job back.—ED.]

Austin, Minn., November 10, 1893.
Austin Electric Company, Dr.

Austin, Minn., November 10, 1893.
C. R. Hyde.

Dear Sir: Inclosed please find notice of expiration on insurance. Shall be in St. Paul Saturday. Want to see Duflie if possible. Have another scheme to lay before him relative to another contract with the city. Very truly yours, W. S. PIERCE.

Austin, Minn., November 1, 1893.
C. R. Hyde.

Dear Sir: Will hold checks till collections are made to cover the same. We are at work on the commercial circuit now. We can not connect up on switchboard till bank boards come. Very truly yours,
W. S. PIERCE.

Austin, Minn., Nov. 13, 1893.
C. R. Hyde.

Dear Sir: I found the company's account overdrawn only $9.90 at Citizens' Bank after paying the $70.00 check, and have covered the amount out of personal funds, and enclose duplicate deposit slip.
Very truly yours, W. S. PIERCE.

Austin, Minn., Nov. 17, 1893.
C. R. Hyde.

Dear Sir: Enclosed please find another deposit slip, which makes $20.00 I have put up at the C. N. Bank. This covers all checks and a little more I know of. Received the note for the money advanced on the street job, but not the back salary of $300. I supposed the company would send a draft for this last amount as I gave them time on the other. I made the first all-night run with street lights last night. Everything went all right and gave tip-top satisfaction. I shall reach out now for more commercial and resident lights. The dynamo we have will be unable to carry the load in a short time, and there is no way out unless we run both engines during the heavy load; *this means coal*, and hence there should be no time lost in getting a 1,000 light dynamo in place of one of these. Enclose some newspaper clippings which give an idea how the street lights are received by the public. This time of the year *takes coal* and makes us look down our noses. Very truly yours,
W. S. PIERCE.

Austin, Minn., Nov. 18, 1893.
C. R. Hyde.

Dear Sir: This all night business eats up coal like everything with this kind of a steam plant. This whole steam plant is an abortion from start to finish, and simply places on the company's shoulders the effects of the plans and work of a combination of a pack of fools. This station is heated with radiators, and these radiators are not connected with the exhaust steam but the live steam from the boilers. This is one instance of the economy planned in this plant. You will have to order 2 or 4 cars of COAL, because by the time it gets here we shall need it. *I can see no way by which this plant can make any money under present conditions. The outlook in the electrical industry to my mind is gloomy in the extreme.*

I have lost all the money I can stand in the cursed business, and don't propose to lose any more unless I am forced.

Now, then, I am reliably informed by one of the stockholders that the General Electric Company is preparing to dissolve or go into receivership.

The Northwest Company owes me one note of $2,200 and $300 back salary. It seems they make no effort to pay. I had the promise of the $300 from Mr. Levis while in St. Paul, but they slip out by saying I have been transferred to the Austin plant pay roll.

Strictly on the quiet, I wish you would give me the true facts why my salary is held back after advancing money out of my own funds to keep the business up. Just between you and myself personally I am red-headed, and unless some money comes my way in the near future I shall step down and out, and take radical measures to collect my due.

If the whole thing is going to crash, let the cross fall on those who have placed the company, and not on a weak cuss who has simply worked and obeyed orders. Let this letter be confidential and greatly oblige,
Very truly yours,
W. S. PIERCE.

Austin, Minn., Nov. 19, 1893.
C. R. Hyde.

Dear Sir: I am forced to hire one man extra for three or four days to help change transformers from all night to twelve o'clock circuit, but such a change pays vastly more than the expense comes to. We must exercise every means possible to save fuel, because the consumption for all-night work scares me nearly out of my boots. Expense must be cut down as low as possible. Very truly yours,
W. S. PIERCE.

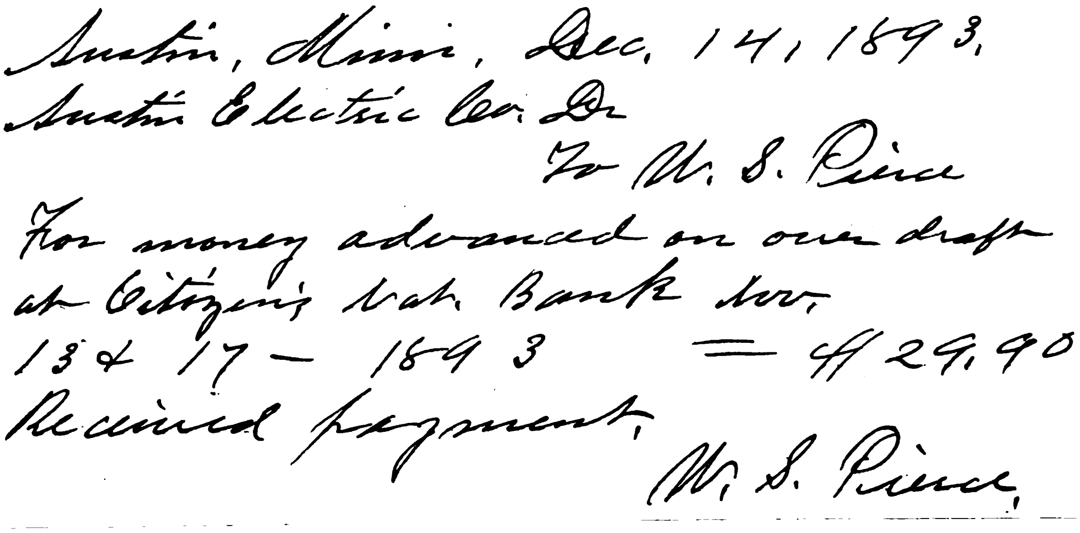
Austin, Minn., Nov. 22, 1893.
Howard C. Levis.

Dear Sir: While in St. Paul, I had but a few hours in which to do anything, because I had work here pressing a homeward march. After mentioning the condition of things here while in your office, I supposed I could go to the cashier and draw my salary up to Nov. 1st, but found only $75 placed to my credit, leaving $300 which I did not get. I advanced all the money for installing the street lights here, and in settlement got only a six-months note. This leaves me so I very much need my salary up to Nov. 1st, and in transferring me to the Austin plant account amounts to nothing because I have just advanced $30 more to that Co. to satisfy overdraft at the bank. I do not consider myself at work for the Austin Co., but for the N. W. Co. as before. When I came here I understood my salary was to be paid as before, and that I was here temporarily to bring about certain results. While these results are being realized, yet I cannot look to the Austin Co. for my pay, inasmuch as I have rendered them more aid now than is my duty, and inasmuch as this Co. has no cash at hand. If you will speak to Mr. Duflie or Mr. Hyde in relation to this matter, they will explain more fully than I can in this letter. Hoping to hear from you in the near future I remain
Yours very truly, W. S. PIERCE.

Austin, Minn., Nov. 30, 1893.
C. R. Hyde.

Dear Sir: Will make report of running supplies on hand promptly. One thing we have none at all on hand, and that is COAL. We are now running on borrowed coal. Please hurry up the last shipment. During the last two weeks there has been no end of trouble. First we tried to light the streets and supposed the tissue paper cutouts were all right. They did work well for a few nights, but all at once they cut out circuit after circuit till all the lights were out in spite of all the relief lamps we had. Then we fused up a little heavier, but they all went the same way again, breaking lamps and making lots of extra work and loss of light. We now have them fused with the right thickness of paper after several trials. Then again, the incandescent dynamo refused to generate, forcing me to take her apart. Found a lead wire grounded on the armature core. Have it repaired all right now. Next in line was the 50 light arc machine; while running all right she burned off a lead wire, and that had to be ripped up the back. Have that repaired all well and good. Next in order, our load was so heavy with the streets that our compound could not carry the load with 125 pounds of steam, yet our inspection certificate allowed only that much. I had the boilers tested for 135 pounds and now the engine carries the load. We can take on no more, however, unless we run both engines and that will not pay as the plant is now constructed. Will explain the reason why when I see you. Have worked days and nights for two weeks and a nearly dead. Have done nothing collecting yet. W try to get about that at once. In haste.
W. S. PIER

Better send a signed check blank so I can pay freight on coal promptly when it comes. I have money myself and the Co. still hold back the due for Sept. and Oct. salary.



Austin, Minn, Dec. 14, 1893.
Austin Electric Co. Dr
To W. S. Pierce
For money advanced on over draft at Citizens Nat. Bank Nov. 13 & 17 – 1893 = $29.90
Received payment,
W. S. Pierce

THE INEFFICIENCY OF THE DIRECT METHODS OF CONVERTING HEAT INTO ELECTRICAL ENERGY.*

BY LEON LE PONTOIS.

The production of electricity directly from heat is a problem which has occupied the attention of many able electricians. Could the enormous energy latent in coal and solar heat be made to appear as electric energy, by means of a simple transforming apparatus, more efficient and less cumbrous than steam or gas engines driving dynamos, there is no doubt that great progress might be accomplished thereby, and that one of those grand steps of progress would be taken of which the nineteenth century so justly boasts.

Unfortunately, it seems that there is no economical solution to the problem. Three quarters of a century have nearly elapsed since Seebeck discovered that by heating one of the junctions of a metallic circuit, consisting of two metals soldered together, an electric current was produced. The science of thermo-electricity thus originated has been developed by Becquerel, Pouillet, Pelletier, Mathiessen, Thomson, but these distinguished scientists and experimenters have never succeeded in producing an apparatus by means of which more than 2 per cent. of the heat energy could be converted into electricity.

Experiments have been made in another direction. Electricity has been obtained from heat by heating and cooling magnetic circuits in rapid succession, so as to modify their magnetic reluctance, thereby inducing alternating currents in coils surrounding such circuits. Thomson, Berliner, Edison, Tesla, have devoted some time to this mode of conversion, and although such ingenious apparatus as the pyro or thermo magnetic generator have been the outcome of their work, as far as we know the efficiency obtained by this mode of conversion has never been superior, if equal, to the efficiency of the thermopile.

Can these persistent failures be attributed to the fact that such distinguished experimenters and scientists have not as yet struck the right process of conversion, or must we come to the conclusion that after all the most economical solution to the problem lies in the construction of a more perfect heat engine driving the already highly efficient dynamo? My opinion is in favor of the latter mode of conversion, and I will endeavor to bring before you as clearly and briefly as I can a few of the reasons on which my belief is based.

Let us consider first the case of the thermo-electric battery. Here is one of a very simple construction; it consists of a bar of bismuth bent twice at right angles, at the ends of which are soldered two copper strips which terminate in two binding screws connected to a galvanometer. If one of the solderings is heated, the needle of the galvanometer is deflected, indicating the passage of a current from the heated to the cool junction; the deflection is greatly increased if the other junction is cooled at the same time.

Thermo-electric currents have long been attributed to an electromotive force produced by the contact of heterogeneous substances, a force which varies with the temperature. Becquerel ascribes them to the unequal propagation of heat in the different parts of the circuit. He found that when all parts of a circuit are homogeneous no current is produced on heating, because the heat is equally propagated in all directions. This hypothesis has been confirmed by many experiments showing that thermo-electric currents can be obtained in a monometallic circuit when a source of heat is applied between two neighboring points of the circuit under different atomic structure.

We will now attempt to show how the unsymmetrical propagation of heat waves along a metallic circuit is attended by the manifestation of electric force. But before going any further I beg leave to remind you of two strange facts of the thermo-electric science which are known as the Thomson and Peltier effects.

Thomson found that when a wire, which is the seat of unidirectional electrical disturbance, is heated, heat waves are not equally well propagated on both sides of the heated point; that is, the apparent conductivity for heat seems to be greater in one direction than in the other. This phenomenon shows that there is a close relation between electricity and heat. Indeed Hertz's experiments have demonstrated beyond doubt that light, heat and electricity, which have their origin in a vibratory motion of matter, are propagated by ether at an equal rate of speed. Moreover, Hertz has shown that an electrical disturbance, so improperly called "electric current," is not all propagated in the wire itself, but under all circumstances penetrates from without into the wire, and spreads into the metal with a comparative slowness. Now the electric force makes itself manifest by heating effects in the conductor, but more especially by a state of stress exerted in the medium surrounding the conductor, which stress is characterized by the magnetic properties exhibited by the medium.

The formation of this field of magnetic force is progressive, and is attended—while it takes place—with radiation of electric waves throughout the medium. Now, if the formation of magnetic whirls around the conductor characterizes these long ether waves known as electric waves, why should not the propagation of these shorter ether waves called heat waves, along a conductor, be also attended with the formation of magnetic fields of force in the surrounding medium?

It seems pretty well established that the only difference existing between electric waves and light waves is solely a question of wave length. Both are electro-magnetic disturbances. Why not extend this appellation to heat waves, which are much more likely to present the same characteristics as electric waves by reason of their wave length, being much longer than the wave length of light waves? It is very likely that these three apparently different forms of energy—light, heat, electricity—are endowed with the same capacity of exhibiting effects which we attribute exclusively to electricity. The only reason why they do not apparently possess the same electric capacity must be attributed to the fact that the bodies which we consider as conductors of electrical energy (because they prevent it being dissipated) present great resistance to the propagation of the rapid vibration characterizing heat, and an almost insuperable resistance to the more rapid vibration causing on our retina the sensation of light.

If we introduce this hypothesis in the study of thermo-electric phenomena, their understanding becomes absurdly easy. Let us take up, for instance, the case of the Thomson effect. A conductor AB is the seat of an unidirectional electric disturbance of direction AB. A source of heat—say a Bunsen burner—is applied in C. The propagation of heat waves on both sides of this point will be attended with the formation of two thermomotive forces equal and opposite. One of them will tend to decrease the original electromotive force, the other will tend to increase it. Whatever be the value of the original vector, as long as it is not zero, the thermomotive force of direction BA will be decreased, while the thermomotive force of direction AB will remain unaltered. Now, if the circuit is closed, it is obvious that the flow of heat energy in one direction will be greater than the flow of heat energy in the opposite direction. Thus heat is unequally propagated on both sides of the heated point.

The Peltier phenomenon is a consequence of the Thomson effect. When a current is propagated across the junction of two metals having different atomic structure, the junction is heated when the current is in one direction and cooled when it is in the other.

Let us consider two bars of antimony and bismuth, AB, soldered together in C. When a current is propagated in the direction AB, the bars become unequally heated on account of the resistance of antimony being greater than the resistance of bismuth. This causes a difference of heat potential between the two metals, and heat waves are propagated from the antimony to the bismuth. According to what we have seen previously, the action of the current tends to direct the largest part of the heat towards the soldered point, therefore its temperature is higher than the temperature of any part of the circuit. If now, the current is propagated in the direction BA, it can readily be seen that the result will be quite opposite, and that the point C will be the coolest point of the circuit. Allusion has already been made to thermo-electric currents produced when a circuit composed of two different metals has the two junctions unequally heated.

A variety of notions has been entertained by physicists as to the origin of thermo-electric currents. They generally have been attributed to an electromotive force produced by the contact of heterogeneous substances, a force which varies with the temperature. A few years ago, Dr. Oliver B. Lodge, the eminent English physicist, succeeded in a certain measure in demonstrating the probability of this hypothesis—in the particular case of a copper iron couple heated at some temperature below 275 degrees C. But the same hypothesis is not verified in many other combinations.

Becquerel ascribed them to the unequal propagation of heat in the different parts of a circuit. He found that when all parts of a circuit are homogeneous no current is produced on heating, because the heat is unequally propagated in all directions. But if uniformity of this is destroyed by coiling it in a spiral, or by knotting it, thermo-electric currents result from the unequal propagation of heat on both sides of the heated place.

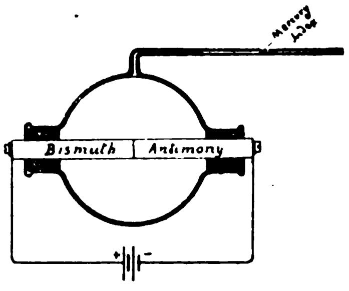


FIG. 1.—APPARATUS FOR DEMONSTRATING THE PELTIER EFFECT.

As, however, Becquerel employed a red heat in his experiments, it is possible that the current obtained was due to a softening of a portion of the wire, while the knotted portion retained its hardness.

I made an experiment which tended to prove this. I had a copper ring, about 10 inches in diameter, vertically mounted on a horizontal spindle. A little above the superior part of the ring a magnetic needle was delicately suspended by a silk thread and kept by the thread in the same place as the ring. A Bunsen burner and air blast were placed so as to heat and cool simultaneously the lower part of the ring. Thus a portion of the ring was softened while the other was hardened. If, now, the ring was slowly rotated on its axis, the intermediate portion was heated, and the deflection of the needle indicated that a current was circulating through the ring from hard to soft. After a few moments the needle would come back to its former position, but if the ring was slowly rotated the defection of the needle was kept nearly constant, and the angle of deflection was maximum for a certain speed, which was about 50 revolutions per minute—the angle of deflection increasing according to a parabolic function when the difference between the temperature of the hot and cool portions of the ring was increased.

I made some experiments with a view of increasing the efficiency of the apparatus. I used a series of rings 1-100 inches thick, coated with lampblack, and separated by small washers. The rings were mounted on iron spiders, and when they were set in rotation the spider and the shaft were very thoroughly magnetized—the plant efficiency was of course considerably increased, but the economical efficiency was practically the same; as in the former experiment, and as far as I could ascertain, it was about 1 per cent. or nearly so.

---

* Paper read before the Engineers' Society of Western Pennsylvania.

This experiment seems to demonstrate that Becquerel's hypothesis is based on facts. The unequal propagation of heat in a metallic circuit may be caused by differences in thermal conductivity—by unequal decrease of temperature on both sides of the heated place. It may also be caused by differences in the specific heat of the two metals, or at two neighboring parts of the same metal, but whatever is the reason on account of which heat is unsymmetrically propagated on both sides of a heated point, it seems to me that the explanation of the phenomenon could be found in analyzing carefully these different causes.

I picture to myself what is going on inside a thermopile as follows: The propagation of heat waves on both sides of the heated point is always attended with electrical displacements in the surrounding medium which affect more or less the inside of the conductor. If the circuit is homogeneous, the resultant of the electric force inside the conductor is zero, but if such is not the case, the resultant is something different from zero, and an unidirectional electrical disturbance or current takes place inside the conductor.

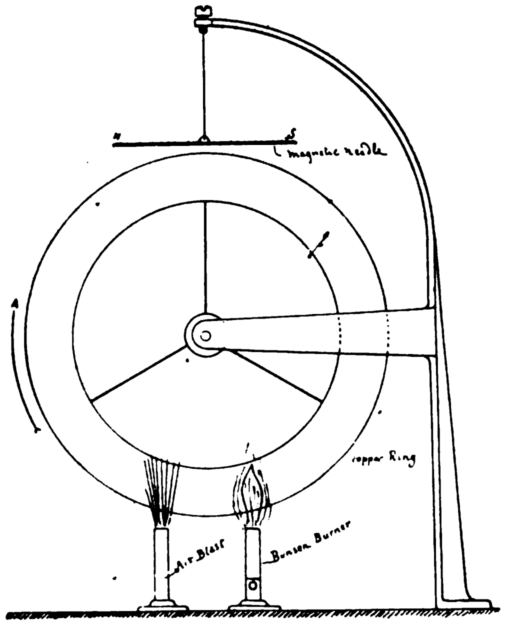

FIG. 2.—THERMO-ELECTRIC GENERATOR.

Now, it is obvious that the dissipation of a certain amount of heat energy in a thermopile must be attributed to a loss by radiation or convection, and to the absorption of heat energy in the atomic motions which determine the manifestation of electrical energy.

The thermopile may be considered then as an imperfect heat engine working between two temperatures, and its theoretical efficiency calculated as follows:

Let t and t_1 represent the temperatures of the hot and cold junctions; e the E. M. F. per degree Centigrade. The total E. M. F. will be represented in this case by $E = e\,(t-t_1)$ and the current by $C = \frac{e\,(t-t_1)}{R_1+R_2}$, R_1 and R_2 representing the internal and external resistances.

According to a well-known law of electrodynamics, the efficiency of a battery is maximum when the internal resistance is minimum. Thus in the particular case of the thermopile the efficiency depends directly on the specific resistance of the metals used. By looking over the following thermo-electric series, we can see that by choosing badly conducting metals, such as bismuth and antimony, or still better, bismuth, cobalt; potassium, nickel; sodium, lead; tin, copper; silver, platinum; gas coke, zinc; cadmium, strontium; arsenic, iron; red phosphorus, antimony, tellurium, selenium. With selenium and tellurium the efficiency is greatly increased; chosing non-conductors, it becomes enormous, but when we use non-conductors we cannot expect to excite currents flowing in closed circuits; we can only expect electrostatic forces.

It seems to me that the best way to treat the problem is to consider the case in which the external work done by the battery is maximum, and calculate the efficiency corresponding to that maximum; the maximum work of a battery is obtained when the internal resistance is equal to the external resistance, then we will have $W = \frac{e_2\,(t-t_1)^2}{2R_1} - \frac{e^2\,(t-t_1)^2}{4R_1} = \frac{e^2\,(t-t_1)^2}{4R_1}$ which expresses the value of the minimum work.

The internal resistance depends on the dimensions and the specific resistance of the bars constituting the battery.

Let r_1 and r_2 represent these specific resistances, and s_1 and s_2 the sections of the bars, having a length L, we shall have $R_1 = L\left(\frac{r_1}{s_1} + \frac{r_2}{s_2}\right)$.

The external work per second is, therefore,

$$W = \frac{e^2\,(t-t_1)^2}{4\,L\left(\frac{r_1}{s_1} + \frac{r_2}{s_4}\right)}.$$

Now let us compare this useful work to the energy wasted by the ordinary conductivity of heat along the bars.

If we represent by Q the amount of heat propagated and $r1^1$ $r2^1$ the thermic resistances of both metals, we have $Q = (t-t_1)\left(\frac{s_1}{r_1{}^1\,L} \div \frac{s_2}{r_2{}^1\,L}\right)$.

The amount of heat energy, furnished at a temperature t, which can be transformed into mechanical work by a perfect heat engine, working with a temperature difference $t-t_1$, is $\frac{t-t_1}{t_1}$. Therefore the heat lost per second will be in our case

$$\frac{J(t-t_1)^2}{t_1}\left(\frac{s_1}{r_1} + \frac{s^2}{r^1{}_2}\right),$$

J representing the mechanical equivalent of heat.

The relation existing between this wasted energy and the useful work is

$$\frac{4J}{te^2}\left(\frac{r_1}{s_1} + \frac{r_2}{s_2}\right)\left(\frac{s_1}{r_1{}^1} + \frac{s^2}{r^1{}_2}\right),$$

an expression which is absolutely independent of $(t-t_1)$ and of L.

The resistance being given, $\frac{s_2}{s_1{}^1}$ must be determined so as to make $\frac{s_2}{s_1}$ a minimum; this condition is fulfilled when $\left(\frac{s_2}{s_1}\right)^2 = \frac{r_2}{r_1} + \frac{r_2{}^1}{r_1{}^1}$; thus the expression giving the efficiency corresponding to the maximum work becomes $\frac{4J}{tL_2}\left(\sqrt{\frac{r_1}{r_1{}^1}} + \sqrt{\frac{r_2}{r_1{}^2}}\right)^2$.

I have applied this formula to the case of german-silver iron couple, and found for the value of the efficiency corresponding to the maximum work, 1.358 per cent. Of course, I do not give this value as being absolutely correct, for the exact determination of the specific resistance is an extremely difficult operation. However, I believe that this value is about correct, for I have made similar measurements on a copper iron couple and obtained nearly the same results.

Two characteristic figures enable us to compare the efficiency obtained by the direct method of conversion through the thermopile and the efficiency obtained by driving a dynamo by means of a gas engine. The Clamond Carpentier thermo-electric battery, which is recognized as being the most efficient, consumes 25 cubic meters per kilowatt hour. A good Otto gas engine driving a dynamo spends about 1.35 cubic meters per kilowatt hour. Hence the thermo-electric battery, to produce an equal quantity of available electric energy expends nearly eighteen times as much heat energy as the gas engines directly driving the dynamo.

(*To be continued.*)

A MODERN BRITISH ELECTRIC LIGHT STATION.*

BY H. R. J. BURSTALL.

The Edinburgh municipal plant was finally opened on April 11, 1895. Having regard to the different districts to be served, and taking into account all the local circumstances, a low-tension three-wire system was adopted for the central and northern district, and an alternating-current high-tension system for the southern and eastern district, both systems being worked from one central station and under the same control and management.

The boiler house is designed to contain seventeen boilers, of which at present only six at the west end are in place.

The boilers are of the dry-backed marine type, each 10¼ feet mean diameter and 12 feet long, with two Purves flues, 3¼ feet inside diameter, and 166 tubes of 3 inches internal diameter.

On the top of the boilers are fitted superheaters, each consisting of two nests of tubes enclosed between the top of the boiler shell and a fire-brick casing above, with a space left in the center for the steam-valves, safety-valve, etc. Sinclair's mechaniical stokers are fitted to each boiler, and are worked from two lines of shafting, which are carried by the columns of the boiler house and driven by an electric motor.

The pump room contains at present one duplex steam-pump and two three-throw pumps driven electrically; each pump has a maximum capacity of 4,500 gallons per hour. The electrically driven pumps are specially designed to run with a large range of speed; and for this purpose can be connected with either the 230-volt or the 115-volt mains. In the pump room is placed the electric motor for driving the mechanical stokers with its countershaft; and there is ample space for more pumps when they are required.

The engine rooms are each about 102 feet long, and are side by side, forming really one room divided by a line of columns. The engine room next the boiler house is reserved for the low-tension plant, the other contains the high-tension plant. A platform, raised 4 feet above the engine-room floor-level, runs the whole way across the west end of both engine-rooms, and on this are placed the switchboards and regulating gear for both the low and high tension systems, as well as the office of the engineer on watch.

The machinery at present in the low-tension engine-room consists of eight engines, four of 100 I. H. P., two of 250 I. H. P., and two of 360 I. H. P., with their dynamos; and provision is made for eight more engines of 360 I. H. P. in the future. All are Willans central-valve engines driving their dynamos direct. All the dynamos are two-pole shunt-wound machines with drum armatures, all wound to give 270 volts, except two which are driven by two 100-I. H. P. engines; these two are wound to give 135 volts, being used as balancing machines on the three-wire system.

An 8-ton traveling crane, running the whole length of the engine block, is provided in each engine-room, for convenience in overhauling, etc. These cranes are worked entirely from below by means of ropes.

The main leads from the dynamos are drawn through curved wrought-iron pipes let into the concrete, into chases in the center of the engine foundation-block, along which they are carried to the chamber under the switchboard platform. The leads from the field winding of the machines are also carried in the same manner to their regulating resistances, which are placed under the platform; the switches for these resistances are fixed upon the handrail on the platform, in front of the switchboard, the leads from the resistances being brought up through the posts of the handrail.

The switchboard consists of seven slate panels each about 7 feet high. The instruments and gear for regulating the battery are mostly placed on the center panel, and those for the switching and manipulation of the dynamos and feeders are on the six outer slates; the connections for the positive side of the system are on the left hand, those for the negative on the right, and the middle wire is connected on the center panel.

---

*Abstract of paper read before the Institution of Mechanical Engineers in London, Oct. 24, 1895.

BALANCING MACHINES.

The foregoing description applies only to the high-volt machines; the connections for the balancing machines are somewhat different. The leads for each of these dynamos are connected—through fuses, ampere meters and automatic switches, as for the high-volt machines—to two contacts of a double-pole switch on the center panel, and can be connected alternatively with two of three contacts, one of which is connected to the middle wire and the other two to dynamo bars on the positive and negative sides of the switchboard respectively. Thus each balancing machine can be put between the middle wire and either the positive or the negative side of the switchboard. These machines are run in exactly the same manner as the high-volt machines, and the whole of their regulation is done from the switch platform.

In the circuit of each dynamo is a registering ampere-hour meter, from which are taken readings whenever the machine is started and stopped; and the station records of the units generated are made up from these readings. Voltmeters are provided, which can be connected to the terminals of each dynamo by means of multipolar switches; other voltmeters are also connected, so as to show the electromotive force between any of the omnibus bars on the positive and negative sides and also between the omnibus bars and the middle wire. A pair of voltmeters are fixed on the upper part of the center slate, and are connected through multipolar switches so as to show the pressure between the middle wire and the positive and negative wires respectively at any feeding point on the system; and for this purpose light wires are brought back from the feeding points. The switchboard attendant is thus able to know directly the electromotive force on the distributing mains and regulates the electromotive force at the switchboard so as to keep this constant.

The two lower horizontal omnibus bars can be connected by plugs to any feeder or any dynamo; by this means it is possible to run any feeder or feeders at a higher or lower electromotive force than the others, should occasion arise. The same two bars are also used for testing, and for the introduction of standard instruments into the circuit of any feeder, dynamo or battery, for the purpose of checking or calibrating the switchboard instruments without breaking any permanent connections or running the circuit on temporary connections. The instrument or standard resistance, etc., is connected between two of the omnibus bars, and the dynamo or feeder, etc., is plugged on one of the lower omnibus bars; the current passes through the resistance, etc., to the top bar, which is on the outside circuit. In the actual running of the station considerable use is made of these spare omnibus bars.

The battery consists of 132 cells of the new Crompton-Howell 31-plate type. It is arranged in two tiers on four rows of stands, which are of cast-iron with wooden longitudinal bearers, carrying the cells; the eight hospital-cells are arranged on separate stands. All the cells are similar, and have each a nominal capacity of 1,000 ampere-hours, the normal rate of discharge being 200 amperes. They are contained in lead boxes, and stand on glass-oil insulators upon the longitudinal wooden bearers.

The high-tension portion of the station consists at present of only two engines and alternators with their switchboard, and the rectifiers for arc-lighting with their regulating arrangements and switchboard; but in the immediate future this plant will be considerably extended. Each of the alternators is driven direct by a Willans three-crank engine of 150 I. H. P. on the same bedplate. The alternators are of the "Portsmouth" type, with some modifications necessary owing to their increased speed of 450 revolutions per minute. The exciting current is taken from the low-tension switchboard at 230 volts, and is only a few amperes. The alternators work at an electromotive force of between 2,000 and 2,200 volts with a frequency of 52½ complete alternations per second.

The switchboard is built up of slabs of slate, forming shelves projecting from the west wall of the engine-room, and divided up into compartments for each alternator and circuit by slate partitions. The outer pole of each circuit and each alternator is connected to an earth plate at the station, the whole of the rest of the system being insulated from earth; owing to this arrangement all the switching can be done on the inner pole, which renders the switchboard and its manipulation very simple. The inner pole of each alternator and each circuit is connected to two similar switches through ampere meters and fuses, and can by these switches be connected to either or both of two omnibus bars at the top of the switchboard. In this way any alternator and any circuit can be connected, and the system can be worked at two different electromotive forces if necessary. The primary object of this arrangement, however, is to enable a machine to be thrown into circuit rapidly by running the machine up to full volts on one omnibus bar, and changing circuits over from the other omnibus bar, on which the other machine is running, without having to synchronize the second machine; the two omnibus bars can then be synchronized, the alternator and circuits changed over at leisure, and all the circuits and alternators run in parallel. In the outer circuit of each alternator is connected a registering watt-hour meter for measuring its output. Voltmeters are connected between both of the inner omnibus bars and the outer omnibus bar; and duplicate synchronizing transformers with lamps and switches are provided between the two inner omnibus bars. In the exciting circuits are ampere meters and regulating resistances, the switches of which are placed opposite the switches and ampere meters of their respective machines. At present the switchboard is arranged for only two alternators and two circuits; but it can be readily extended when required, the gear for new circuits extending in one direction and that for new alternators in the other. The two circuits are at present connected only to the rectifiers for arc lighting.

Opposite to the alternators, and standing on the same foundation block, are placed the Ferranti rectifiers for the series arc lighting. These are three in number, one for each of the two circuits and one to spare. They each consist of a self-regulating transformer, of which the primary winding is connected to the omnibus bars of the high-tension switchboard, and the secondary winding is connected through a commutator and distributing switchboard to the arc lamps. One winding is hung on knife-edges in a frame, and is capable of movement nearer to and further from the other; this automatically keeps the current in the secondary winding constant at 12 amperes, varying the electromotive force to suit the number of lamps in circuit. The current from the secondary winding of the transformer is then changed, by a commutator driven by a synchronous motor, from an alternating current to a unidirectional pulsating current, which is distributed to the lamps. A small distributing switchboard is placed close to the rectifiers, by means of which any rectifier can be put on to either of the high-tension omnibus bars, and either circuit of arc-lamps can be put on to any rectifier; and provision is made on this switchboard for extending the number of arc-lamp circuits.

In the engine room the low-tension plant comprises eight Siemens dynamos; two have each an output of 450 amperes at 135 volts; two of 220 at 275; two of 600 at 260, and two of 865 amperes at 260 volts. The contractors for the engines, dynamos, steam and exhaust piping, feed-pumps, heaters, etc., were Messrs. Siemens Brothers & Company, who also supplied the switchboard and all connections. The high-tension plant in the engine room consists of two alternators, each having an output of 40 amperes at 2,100 volts, a high-tension switchboard, and three rectifiers for arc-lighting, with switchboard. The contractors for the whole were Messrs. S. Z. de Ferranti.

In the three-wire system of distribution for the northern and central district the electromotive force between the two outer conductors, positive and negative, is 230 volts, while that between the middle and the positive or negative is 115 volts. The latter is the electromotive force of the lamps on the consumers' premises, no trouble being now experienced in obtaining glow-lamps to work at this electromotive force, or even higher. All three wires are laid in those streets where the demand for current is large. In the other streets the positive and middle wires are laid on one side of the street, the negative and middle on the other; and a spare way is left on each side for a third conductor should the demand require it. The distributing mains are all in parallel, and are connected up throughout the system; rings are completed wherever possible, so as to ensure equality of pressure, and to admit of disconnections being made without interrupting the supply.

The feeders from the station are connected to the distributing mains at sixteen points. They consist of two conductors only, the positive and negative; the middle wire is interconnected throughout as much as possible, and is brought back from three districts on the system. The cables are put in parallel at the station, and one connection only is made to the switchboard. The positive and negative sides respectively of all the feeders are put in parallel at the switchboard, but any feeder or feeders can be put on a separate machine if required.

As far as possible, consumers in each street and district are balanced against one another by connecting them alternately between positive and middle wires and between negative and middle wires; large consumers have all three wires taken into their premises, and their lights balanced against one another in a similar manner. But however carefully this balancing is done it is impossible to get a really accurate balance; the "out of balance" current varies from hour to hour and even from minute to minute, and is different on different days of the week. The amount out of balance is compensated for at the station by means of the balancing machines, one of which can be put on either side of the system; the balancing during the light load is done from the battery alone. Light wires, forming potential leads or pilot wires, are brought back from all three conductors at each feeding point, and are connected to the feeder voltmeters on the switchboard; so that the pressure at the feeding points at any part of the system is directly known at the station, and the necessary regulation made for keeping the electromotive force constant. The distributing mains are brought back to the station, but are used only for the supply of light and power there; no regulation is done on the mains anywhere, except to the feeding points.

No high-tension feeders or distributing mains have yet been laid. They will be laid as concentric cables in ring circuits, and banked transformers in small sub-stations will be used wherever advisable, while houses in districts where the lighting is scattered will be served by isolated transformers. The concentric cables will be pulled into Doulton stoneware casings under the footways, and into cast-iron pipes under the roadways. The casings have already been laid in those streets which have been opened up for the low tension mains, and the work of laying the high-tension mains in the southern and eastern district is now being proceeded with.

The streets are lighted by means of 176 public arc lamps. In some streets the arc lamps are run four in series off the distributing mains; and each series of four is provided with a fuse, switch and line resistance. Each lamp in the series is also provided with an automatic device which, in the event of the lamp failing, cuts it out and introduces into the circuit a resistance equal to the lamp, so that the other lamps in that circuit are not affected. The lamps in Princes street are constructed for a normal current of 15 amperes, and all the other low-tension lamps for 10 amperes.

In certain streets, in which no low-tension mains are laid, the lamps are run on special high-tension series circuits from the rectifiers at the station. There are at present two series circuits, both of which are laid in all the streets lit by high-tension lamps, and the lamps are connected alternately to each circuit. The circuits are laid as concentric cable drawn into cast-iron pipes, the outer conductor of the cable being insulated. There are twenty-four lamps on each circuit, each provided with an automatic cut-out in case of its failing to act, and also with a switch in the pillar, by which it can be entirely disconnected from the circuit if necessary, while the switch is so made as to complete the circuit for the other lamps.

In arranging the circuits for the arc lamps care has been taken to put alternate lamps on separate circuits in all streets, whether run from the distributing mains or from the series circuits. This minimizes the risk of any street being left in darkness by the failure of any circuit, and also allows half the lamps to be switched off at or about midnight, still leaving the streets well lighted. The arc lamps are of Crompton-Pochin type, and are fitted with 18-inch spherical globes. They hang from the bracket of a cast-iron pillar, the center of the globes being 23 feet above the level of the pavement. In Princes street the lamps are about 45 yards apart and are on one side only of the street. In the other parts of the city the lamps are about 60 yards apart and are placed alternately on the two sides of the street.

THE APPLICATION OF ELECTRICITY TO THE SEWAGE PROBLEM.

Professor John W. Langley has been conducting at the Case School of Applied Science, Cleveland, elaborate experiments on the application of electricity to the purification of sewage. At a meeting of the Cleveland Council of Sociology, held on the 8th inst., he read a paper giving the results of his experiments and investigations.

"The members of the public are quite familiar," said Professor Langley, "with the uses of electricity as a source of light and power, but they have not had their attention called to its uses as a chemical agent. This, too, is a growing field for its employment in electro-metallurgy and in the production of alkali. One of the newest and perhaps one of the most general interest is a proposition to utilize the decomposing power of electricity for the destruction of bacteria and noxious odors, particularly in that fluid which is pre-eminently rich in them—sewage."

Referring to the practical results that have already been accomplished, Professor Langley said:

The plan was first tried in the village of Brewsters, N. Y., which is situated on the watershed of the Croton supply to the city of New York. The drainage from this town found its way into an adjacent marsh and from there into streams running into the Croton basin. An electrical engineer by the name of Wolf proposed to decompose sea water by electrolysis, and to turn the solution of chlorine thus obtained into the drainage from the village. The plan proved to be completely successful, as shown by a report issued by Dr. Cyrus Edson, Health Officer of New York, in 1892 and 1893. By an expenditure of a little over five-horse power to work a dynamo, the sewage was completely disinfected at an estimated cost of less than 1 per cent. of that of the older methods using chloride of lime or carbolic acid.

The next important trial of the new method was in the city of Havre, in France, where it is known as the Hermite process from the name of the inventor, who, in Europe at least, is considered to be the originator of the idea. After an extended trial of the system a commission appointed by the Mayor of the city made a lengthy report, establishing the following points: First—The method is cleanly, practical, and easily carried out. Second—When the disinfecting fluid is allowed to lie a sufficient time in contact with the sewage the bacteria are completely destroyed, none of them survive. Third—An amount of free chlorium one-half a gram to the litre of sewage accomplishes complete disinfection. Fourth—The process as worked at Havre, with the price of coal and wages there prevailing, seems slightly more expensive than the older methods by chemical precipitation, but this might be remedied by further experience.

The next important installation is in the city of Ipswich, in England, where it is now being applied to the entire sewerage system of the town, and with complete technical success if we may judge from a report which appeared last summer in the London journal *Lightning*.

The process consists in pumping sea water or an artificial brine made from salt through tanks in which are placed electrodes supplied with current from dynamos. The chlorides of magnesium and sodium in the sea water are decomposed into alkali at one pole and free chlorine at the other. The latter dissolves in the water and becomes the disinfecting fluid, which is then turned into the sewers or is delivered to tanks in which the sewage is temporarily arrested. The disinfecting fluid itself is colorless and has only a moderate odor of chlorine, while the alkali formed in the decomposition of the salt greatly lessens the corrosive action of the chlorine on metal pipes.

In order to give a scientific basis on which to make estimates of the cost, I have made in the electrical laboratory of the Case School of Applied Science numerous experiments, using an artificial sea water which practically represented the real article. Small decomposing tanks were made after the pattern of the large ones, and the electrical energy used was carefully measured. From these it appears that six and thirty-seven-hundredths pounds of chlorine can be made every hour from one electrical horsepower. This quantity, using the Havre estimate, would purify over fourteen thousand gallons of sewage per day of ten hours. A hundred horse-power would therefore disinfect nearly a million and a half gallons in the same time. The cost of the process will be but little more than the cost of electricity, plus that of pumping the sea water and the small additional amount for wages. These can be approximately estimated at twenty-five cents for 1,400 gallons when carried out on a scale of 500 horse-power. Taking the wholesale price of bleaching powder, its cost to do the same amount of disinfection would be at least twenty times as great. For inland cities the cost of salt would have to be added, but even then the expense would still be much below that of bleaching powder.

This method is one especially adapted to hospitals and large public buildings. No special electric installation would be necessary for buildings already wired for light or power, since a moderate amount of current could be drawn from them. The salt water could be decomposed in moderate sized tanks placed on each floor, and allowed to run into the drain system in small quantities either automatically or by hand regulation. Thus this cleanly and practically inoffensive fluid would fill the traps of the various sinks and basins, and so disinfect all the material while it was yet within the building and before it reached the city sewers.

American Institute of Electrical Engineers.

The 101st meeting of the Institute will be held at 12 West 31st street, New York, on Wednesday, November 20th, at 8 o'clock P. M.

The meeting will be devoted to a topical discussion on "Storage Battery Applications."

Several members, having had experience in this field, have expressed their intention of giving their views, and communications on the subject have already been filed by Messrs. Arthur E. Childs and C. L. Edgar, of Boston; Dr. F. B. Crocker and Mr. Nelson W. Perry, of New York City, and Mr. Carl Hering, of Philadelphia. It is the wish of the Committee on Papers and Meetings that all members who can contribute something of interest on this occasion should send in communications in case they cannot be present.

A similar meeting of Western members will be held the same evening, Wednesday, November 20, at 8 P. M., in the rooms of the Western Society of Engineers, 1737 Monadnock Building, Chicago. The California members will also discuss the subject the same evening.

THE DEPARTMENT OF ELECTRICITY AT THE ATLANTA EXPOSITION.*

If asked to specify the notable features with which the Atlanta Exposition may hereafter stamp itself on electrical history, the writer would be inclined to name electrical transmission over long distances and in factories, and the further differentiation of important classes of work in the department of lighting, heating and intercommunication. The advance in these respects from 1893 to 1896 is thus again individualized just as political evolutions are by successive Presidential terms or the tenure of European monarchs. Those who are intimately familiar with the electrical advances know that the recent three lean years of national depression have been singularly fruitful in valuable innovations and improvements which, perhaps, the reckless disregard of economy manifested in the flush days of prosperity might have left in obscure neglect. As a corollary to this higher refinement and better engineering has come a lower range of prices for apparatus, so that equipments shown at Atlanta may be purchased for prices that would have seemed incredibly low at Chicago in 1893. This again means a boon to the inspecting public and a further popularization of electrical arts and appliances. . . .

MR. LUTHER STIERINGER.

In the case of buildings and grounds, the true principle is to outline and accentuate against the dark background of the night. Thus the imagination is given a chance, and this freedom is pleasant to all intelligent minds. The contour of the landscape is caught, the contrast of light and shadow is agreeably heightened, the expenditure of energy for the given result is minimized, and the spectator whose eye is not stunned or dazzled moves about with serene disposition, the rest given to the optic nerves being felt by the body as a whole. It may be said that success in this respect must depend largely upon artifice. It does, but not of the kind which betrays itself. The artist in light looks upon any subject just as the painter does upon a landscape. He has to compose a perfect picture by means of the disposal of illumination, and he must be judged by the resultant harmonious whole. For example, to erect huge towers and masts for lamps outside buildings would inevitably dwarf the structures. To make each building a blaze of light would blot out the grounds. A sea of light in the paths and lawns would reduce the buildings to islands of darkness; so that the study of interaction, distribution and diffusion becomes for a lighting expert not only a severe problem but a fascinating and absorbing pursuit. In dealing with questions of light for strictly utilitarian purposes, means must be adopted quite different from those that promise success in spectacular displays, but the result is ever a matter of guess-work. The experiment is much the same as the firing of modern heavy artillery; each shot is so costly and so irretrievable when fired, that native genius and prayerful study must be taxed to the full in advance to insure the hitting of the mark. Let the reader of these words, for example, give a few minutes to the lighting of the grounds and buildings as a matter of plan. Be his approval or criticism what it may, he will see at once how extremely difficult it would have been to change this plan after adoption, and, therefore, how much experience and thought must necessarily have gone *into it in* advance.

---

*By Luther Stieringer, E. E., Consulting Electrical Engineer of the Exposition.

. . . Before proceeding to touch on other ex*hibits*, it may be noted that the electrically luminous twin fountains "Atlantis" will embrace water designs of endless variety, including the untried novelty of a "mist bank," supplemented by the hardly less new forms of lily jets, geysers, wheat sheaves, ring curtains and parabolas. The lighting will be done by means of 24 projectors, each of which focuses a beam of light of not less than 250,000 candle-power. The hydraulic part is on an equally imposing scale, water being furnished to the fountains at 100 pounds pressure through a 24-inch main with a capacity of 15,000 gallons a minute. The fountain island is about 100 feet in length by 50 in width, and its jets will shoot to an altitude of full 150 feet.

The Atlanta Exposition will, in the domain of industrial electric lighting, emphasize as with the punctuation of a full stop the close of a most notable period of electrical controversy, namely, that as to the superiority of the direct or the alternating current.

Another point to emphasize is the fact that much of the series arc lighting has succumbed to the use of arc lamps on the direct current incandescent circuits, which, as Atlanta will show, thus combine on one set of wires arc lamps, incandescent lamps, motors and heating appliances. Where series arc light holds its own, economically, it is done by abolishing the small arc machines of 25 or 30 lights shown so profusely several years ago as beau ideals at the Philadelphia Electrical Exhibition and by adopting dynamos that will carry as high as 150 arc lights. Expositionally speaking, the demonstration of this new class of work will date from Atlanta.

As the direct current still maintains its sway and dignity in the field of lighting, motor work and the operation of the ubiquitous trolley car, and is facile princeps in the art of distribution, so the alternating current has found its special and peculiar field in transmission by the electrical utilization of large or remote water powers. The gaze of the world is fixed on Niagara, but since the Chicago Fair a great many plants of similar interest have been put in successful operation.

The storage battery has one of its happiest exemplifications in the electric launches, and the Atlanta exhibit will, commercially, be worthy of observation. The ingenious inventor can make his opportunity here and be very welcome. The storage battery has, until very lately, been the spendthrift and black sheep of the electrical family. Barely now has it reformed, and the road is long that it has to travel before capital can be freely drawn out for its exploitation as it was after the Paris Electrical Exposition in the early '80s. But what there is good of it is to be seen at Atlanta, and the result is far better than any of us dared anticipate before the fleet at Chicago had carried its 1,000,000 passengers with such remarkable success. Visitors to the Fair will note the absence of storage battery railway work—a branch that once was watched and nursed with the liveliest expectations.

Electricity has hitherto been peculiarly the enjoyment of the dweller in the city. May we not hope for the demonstration at Atlanta, choice center of one of the finest raw material portions of the whole world, that electricity is now to be tamed for the service of the farmer?

The second of the suggestions it is desired finally to make is that electricity belongs to no man. Rich as it is in countless beautiful inventions, its unpreempted auriferous soil has scarcely been scratched. Morse and Edison, Brush and Tesla, Bell and Gray, Thomson and Sprague—great as their ideas and discoveries have been, are but exemplars and sign-posts for the younger men who must come after, and of whom the South must furnish its quota.—*Dixie*.

When the Russian squadron came over to participate in the naval display in New York Harbor and Hampton Roads on the occasion of the Columbian festivities in 1892 the Grand Duke Alexander, who was with the fleet, took a great fancy to the electric launch that had been provided as part of the equipment of the United States ship New York. Through the courtesy of this Government the Grand Duke was permitted to purchase this launch. Grand Duke Alexander took his new acquisition back to Russia with him, and it proved to be a source of envy to all who saw it, not excepting the Emperor himself, who has, through the naval attache of the Russian Embassy at Washington, invited bids for an electric boat.

LEGAL NOTES.

RECEIVER FOR THE LOUISIANA ELECTRIC LIGHT COMPANY.

The United Electric Securities Company Wins.

Judge Pardee of the United States Circuit Court at New Orleans has appointed George Q. Whitney and Gen. A. S. Badger receivers of the Louisiana Electric Light Company.

The United Electric Securities Companies of Portland, Me., filed last summer a bill alleging that the Louisiana Company was insolvent, and making very sensational charges of mismanagement by its directors and of malversation of the huge amounts it received for lighting the city. Temporary injunctions were granted and a hard fight was made by the Louisiana people to continue in control.

The American Loan and Trust Company, holders of $670,000 worth of Louisiana Electric Light bonds, have filed a bill in equity asking injunctions restraining Maurice J. Hart and Ronald T. McDonald from disposing of $200,000 worth of Edison Electric Light Company capital stock, which is one of the principal assets of the defendant company.

Marcus C. Gormley has filed a bill in the Circuit Court asking for a receiver for the assets and franchises of the General Electric Street Railway Company of Chicago, and also to cancel a quantity of stock which he says has been issued to various persons.

The Siemens & Halske Company have prepared a series of suits for infringement against a large number of electrical lighting and railway concerns, involving a large sum of money. The patent at issue is on the direct-current booster.

Chief Justice Beasley of the New Jersey Supreme Court has handed down a decision in the case of the Pennsylvania Railroad Company's appeal from the State Board of Taxation in the matter of the taxing by Atlantic City of a trolley line within the city limits. The Court holds that the tracks, ties and like property of the company must be assessed by the State Board of Assessors, but that the electric cars, equipment, electric plant and other property pertaining to the electric railway shall be assessed by local assessors.

Judge Waddell, of West Chester, Pa., on the 12th inst. decided that the city of Chester could not enter into a contract for lighting the city with the Beacon Electric Light Company, and made the injunction perpetual restraining the city officials from entering into such a contract. This action grew out of an attempt of councils to award the contract for lighting the city for five years to a new company at a saving of some $16,000. The Chester Electric Light Company, which has been furnishing the light, asked for the injunction on the ground that the city could not enter into such a contract unless the money was appropriated to pay for the same at the time the contract was signed. The case will be appealed.

THE MICROPHONE QUESTION.

To the Editor of ELECTRICITY.

SIR: Is there really any meat in the "constant contact" chestnut?

Prof. Bell had demonstrated, and published as early as March 7, 1876, that an "undulatory current" was required in the transmission of speech.

In his anticipation of a battery transmitter, in his patent, the intention to have an unbroken circuit is unmistakable—in fact the battery circuit could not be broken by any possible vibration of the diaphragm. This patent was issued fifteen months before Berliner's original application, to say nothing of his subsequent "constant contact" amendment. It was a matter of common knowledge among those skilled in the art at that time that an "undulatory current" could not be produced by broken contact.

Prof. Bell's description of the current required was most perfect "undulatory." If it means anything it means an unbroken current of variable strength. With this to guide them, every early experimenter worked on this line. I do not know of a case where the early descriptions and models do not plainly indicate "constant contact," even if not so worded in the claim.

Edison certainly knew that "undulations" could not be produced by breaking the circuit, and that an intermittent current could not be "undulatory."

In his patent No. 474,230, application filed April 27, 1877, thirty-eight days before Berliner's original application, in Claim 1 he says: "The contiguous faces of said disk and diaphragm being in contact." Too bad he did not say "constant," though the device plainly says it and does it. In Claim 2 he says: "Both having broad surfaces in vibratory contact with each other." Is the English language so flexible as to admit of construing "vibratory contact" to mean vibratory separation? I think not.

I never thought or heard of transmitting by means of broken contact until some years later, when it was attempted to evade the Bell patent by using intermittent instead of undulatory currents. This failed, of course, for two reasons—first, because it did not evade the Bell patent, and second, because it could not be made to work well, as anyone might know who had heard his correspondent talk too loudly in a Blake transmitter.

A. BLAKE.

BOOK REVIEWS.

THE ELECTRICAL TRANSMISSION OF ENERGY. A Manual for the Design of Electrical Circuits. By ARTHUR VAUGHAN ABBOTT, C. E. 567 pages, with 7 curve sheets in pocket. Cloth, 8vo. Price, $4.50. New York: D. Van Nostrand Company.

This work is the first comprehensive attempt yet made to collect together the innumerable details of which it treats. It is truly, as the author calls it, a manual, and as such will doubtless find its way most extensively into the class room.

From the title one would be led to suppose that its chief aim was to lay before the reader the various transmission questions. This it does with sufficient fullness in a descriptive way, but its scope is rather the laying out of circuits than the transmission of currents.

Happily it is by no means a mathematical treatise, only such mathematics being used as is required to show in true relation cause and effect and to enunciate laws. By this means the author has very widely enlarged the usefulness of the work, for there is no one engaged in line construction who cannot understand, nor any one who will not benefit by the possession of the work.

The book is divided into twelve chapters with the following titles:

I—Introduction, which discusses distribution in general, in series, parallel, mixed systems and indirect distribution. II—The Properties of Wire: The Conducting Circuit, Wire Manufacture, Hard Drawing, Wire Gauges, The Circular Mil, Insulated Wire, Testing and Inspecting, Wire Specifications, Tension of Aerial Lines. III—The Construction of Aerial Circuits; this is divided into three heads, viz., General Line Work, Electric Railway Circuits and Lightning Arresters. IV—Construction of Underground Work: 1, Conduits; 2, Cables and Conduit Conductors. V.—Electrical Instruments. VI—Methods of Electrical Measurements. VII—Continuous Current Conductors; *a*, Conductors and Insulators; *b*, Heating of Conductors. VIII—Conductors for Alternating Currents. IX—Series Distribution. X—Parallel Distribution. XI—Miscellaneous Methods and Long Distance Transmission. XII—The Cost of Production and Distribution.

Scattered throughout the work are almost innumerable tables referring to the subject under discussion, and one possessed of this book need scarcely look elsewhere for anything in this line that he may need.

A chapter which will be particularly appreciated by a very large number of people is VIII, on Conductors for Alternating Currents. In this the subject is most fully treated and the methods of calculating them given. Three of the pocket-sheets refer to this subject.

Chapter XII, treating of the cost of production and distribution, is admirably handled, and Pocket-sheet Table 75 enables one to determine without calculation cost of generating plant per H. P. Pocket-sheet Tables 76, 77 and 78 enable one to determine directly, by means of curves, other items of cost.

In connection with 78 there is a small table giving curves for the determination of cost of underground conduit work, and in connection with 77 another smaller one, No. 24, with curves representing the current strength required for elevation of temperature in wires.

GENERAL NEWS.

What Is Going On in the Electrical World.

Cottondale, Ala.—The Tuscaloosa Manufacturing Company will put in an electric lighting plant.

Preston, Minn.—This city has declared by vote in favor of issuing $18,000 bonds for an electric light and waterworks system.

Rochester, N. Y.—The supervisors have adopted a resolution to expend $18,000 for gas and electric fixtures for the new court house.

Thompsonville, Mich.—The vote taken on the question of bonding the village for electric lights was almost unanimous in the affirmative.

Tacoma, Wash.—The city's electric lighting business has increased beyond the capacity of the plant and the power of the plant is to be increased.

Mauch Chunk, Pa.—At the election in East Mauch Chunk the citizens voted to bond the town in the sum of $15,000 for the erection of an electric light plant.

Corunna, Mich.—At the recent election there was a large majority vote in favor of bonding the town in $30,000 for waterworks and an electric light plant.

Madison Ind.—Proposals are wanted by the city of Madison for the purchase or lease of its electric light plant and for the construction of an electric railway in connection therewith.

Gowanda, N. Y.—At a special election held on the 9th inst. the taxpayers voted for the appropriation of $1,200 per year for the maintenance of electric lights to light the village streets.

Fulton, N. Y.—The Oswego Falls and Fulton Street Railway has changed hands and will be converted into an electric road, with the probability of its extension to the city of Oswego.

New Orleans.—J. J. Cohn, M. Ber and associates have petitioned the city council for a franchise permitting them to establish an electric lighting plant and to furnish light to the citizens.

Brunswick, Ga.—An effort is being made to get outside capitalists to take hold of the street railway here, transform it into an electric road and extend the system. Col. W. A. Jeter is promoting the scheme.

Schenectady, N. Y.—The second of three electric locomotives which are being constructed at the General Electric works in this city for the Baltimore and Ohio railroad was sent away from the works last week.

Hagerstown, Md.—Powell Evans, representing a Philadelphia syndicate, has bought out the Schuyler Electric Light Company of Hagerstown. Mr. Powell and his associates have the contract for lighting the streets.

San Leandro, Cal.—At the next meeting of the San Leandro town trustees, the ordinance calling an election on the question of bonding the city for the purpose of providing an electric light plant will be finally passed; the amount decided on is $10,000.

Boston, Mass.—Brookline is to have a new electric railway, to be known as the Brookline Street Railway. Its promoters are some of the best-known business men and financiers of Boston, Newton and Brookline, who will have the co-operation of moneyed men of New York.

Yonkers, N. Y.—A fire at the car shed of the New York and Putnam Railroad Co., at Van Cortlandt Park, destroyed a number of cars and a new electric motor. The motor was valued at $6,000 and the secret of its construction, which belongs to the company, at many thousand dollars more.

Oxford, Pa.—Farmers and citizens in the neighborhood of Cochranville have subscribed $14,000 and given rights of way for the proposed electric railway from Philadelphia to Lancaster via Cochranville. A branch will be constructed to Oxford.

Mechanicville, N. Y.—The water power below this village has lately been inspected by capitalists who are reported to have in view the erection there of a great electric power plant to furnish heat and power for the electric railroads in the vicinity and also for Troy and Albany.

York, Pa.—The electric light plant of the borough of Delta, this county, was destroyed by fire on the 11th inst. The loss is about $2,000, partly insured. The plant will probably be rebuilt.

Pottstown, Pa.—The survey of a large portion of the route for the electric railway between West Chester and Pottstown has been completed and the construction work will begin in a short time.

Frederick, Md.—The board of managers of the Frederick-Middletown Electric Railroad have adopted a route for the proposed road. They are now closing contracts for the right of way. The work of grading will soon begin.

East Orange, N. J.—The Suburban Electric Light and Power Company, which was recently given a franchise in East Orange, has secured subscribers to its system equal to the capacity of its plant, 1,000 lamps. The plant is to be enlarged at once.

Jersey City, N. J.—It is probable that in a few days advertisements will appear for bids for lighting the city with electric lights under the plan adopted by the Street and Water Board. About three times as many electric lights are to be used as are now in service.

Milwaukee, Wis.—The "Wisconsin" states that the Milwaukee Street Railway Company's property will be sold to the highest bidder within three months, probably shortly after the New Year, and will then be reorganized and operated by a new and strong company.

Glenville, Ohio.—The citizens of Glenville will on December 10 vote on the proposition, which has been favorably passed upon by the council, to issue $100,000 bonds, the proceeds from which will be devoted to the fire department, sewers, electric lighting and water works.

Elizabeth, N. J.—The Consolidated Traction Company have secured dock facilities at Elizabethport and on Staten Island and are arranging for connection with the trolley lines on Staten Island, whereby they can establish rapid transit by a short route from Elizabeth to New York city.

Winchester, Mass.—Col. Charles F. Woodward and others have applied to the selectmen for a franchise for an electric street railway to enter Winchester. If the franchise is obtained and the line built, power for its operation will be furnished by the Wakefield & Stoneham Company.

Chicago.—The recent earthquake damaged the electric plant of the Parisian Circus, on Wabash avenue, by jarring and knocking out of adjustment all the finer machinery, destroying the usefulness of many delicate connections and parts of the equipment. Almost an entire new outfit is necessary, costing about $500.

San Francisco, Cal.—The reconstruction of the Ellis street cable line into an electric line will be completed in about three weeks. It is the intention to eventually extend the road across Market street into Fourth street, and continue down the latter thoroughfare to the Southern Pacific depot at Townsend street.

Vincentown, N. J.—It is stated that the Pennsylvania Railroad Company is so well satisfied with the operation of the Burlington and Mt. Holly branch by electricity that it will soon introduce the trolley on the branch between Evansville and Vincentown and also the Newtown Square branch, starting at Fernwood.

Fenton, Mich.—The common council has granted a franchise of the streets to John E. Nolan, of Saginaw, to construct an electric street railway. Mr. Nolan has a franchise for the city of Flint, and an electric line will connect the two towns, a distance of sixteen miles. It is promised that the railway will be in operation by July, 1896.

Akron, O.—The Rapid Transit Company and the projectors of the second electric road between Akron and Cleveland have pooled issues and will build the road. It reaches Cleveland by a westerly route, while the Akron, Bedford & Cleveland line, already built, takes an easterly course. Philadelphia capital is backing the move.

Richmond, Va.—The stockholders of the Rappahannock Electric Light & Power Company have elected the following officers: H. Browning, president; J. B. Ficklen, vice-president and general manager; A. B. Botts, secretary and treasurer. Directors: H. Browning, A. B. Botts, J. B. Ficklen, Mrs. Letitia Souther and Mrs. C. D. Willis.

St. Louis.—The Franklin avenue car line is having a new track laid, the rails being welded together by the electric process. When completed there will be about ten miles of track thus welded. The rails used are sixty feet long.—A certificate of lease of the Manchester Road Electric Railway to the St. Louis and Meramec River Railroad Company has been filed.

Albany N. Y.—The Mt. Vernon Railroad Company has applied to the State Railroad Commissioners for permission to substitute electricity for horse power and to extend its lines to White Plains, New Rochelle and other points.—A fly wheel in the power house of the Albany Railway Company burst on Wednesday last killing one man, injuring three others, and doing much damage to the building and machinery.

Washington, D. C.—Crosby & Fish have acquired control of property in Georgetown known as the Dent foundry and iron works and intend to establish a plant on the site for the purpose of furnishing electric light and power.—The National Convention of Electrical Workers was held here last week. There was a good attendance from all parts of the country and the meetings were animated and of great interest to the members of the organization.

Baltimore, Md.—Clemens Herschel has approved plans and specifications for the dams, waterways and electrical machinery submitted to him by the Susquehanna Construction Company for the great electric generating plant to be established at Conowingo, on the Susquehanna river. The purpose of the company is to transmit the power developed to Baltimore, Wilmington and other places. The cost of the works as estimated will be about $3,000,000. The company was incorporated at Baltimore on the 7th inst.

Niagara Falls.—Last week, current from the Power Company's works, reduced to 600 volts by the big rotary transformer from the Westinghouse works at East Pittsburg, which had arrived and been set up a day or two before, was turned into the wires of the Buffalo and Niagara Falls Electric Railway and made the cars travel over the road between North Tonawanda and the Falls with unprecedented speed. The Railway Company's own current was cut off for the experiment.

Brooklyn, N. Y.—Sealed proposals will be received at the Department of City Works, Municipal Department Building, until the 25th inst. for the installation of electric light wiring in the municipal building. Plans and specifications may be seen, and forms of proposals may be procured on application at the Department of City Works. F. Kingsbury Curtis, representing the New York Guaranty and Indemnity Company and a special master appointed by the United States Courts, will offer at public sale at 111 Broadway, New York, on December 5 next, the rights franchises and property owned by the Long Island Traction Company and the interest it owns in the capital stock of the Brooklyn Heights and the Brooklyn, Queens County and Suburban Railroad Companies, together with all assets receivable by the Brooklyn Heights Company under the lease of February 14, 1893, and all the interest of the Traction Company in a certain guarantee fund of $4,000,000 mentioned in the lease.

Los Angeles, Cal.—The way in which the work is being pushed makes it likely that before the first of the year the cable roads of the Los Angeles Consolidated Street Railway Company will be operated by electricity. Wires are now being strung on the line and new machinery has been ordered for the generating plant. The chief engineer has fitted up a room at the power house where on certain evenings he gives lectures to the grip men on the uses of electricity and the management of electric cars.

Naugatuck, Conn.—An electric railroad company is to be organized immediately to build a line from Naugatuck Junction southward to the shore, thence to Milford, with extenison to Woodmont and Woodmont station. It will be about eight miles long. Some of the men interested in the proposed railroad are Gen. G. H. Ford of New Haven, ex-Sheriff Charles A. Tomlinson, ex-Judge William B. Stoddard, ex-Senator George M. Gunn, ex-Representative Tibbals and Charles W. Beardsley.

Asbury Park, N. J.—Articles of incorporation and a map of location have been filed at Trenton, showing the proposed route of a new trolley road to be constructed from Belmar to Point Pleasant. This road is to be known as the Asbury Park, Belmar, Spring Lake and Manasquan Division of the Atlantic Highlands, Red Bank and Long Branch Electric Railway Company. The road, after belting the town of Belmar, will pass through Como, North Spring Lake, Spring Lake, Sea Girt, Manasquan, Brielle, and Point Pleasant. Connections will be made at Asbury Park with the Atlantic coast line, which runs to Long Branch and Pleasure Bay. Work on the new line will be begun at once.

Philadelphia.—The management of the entire business of the consolidated street railways is to be turned over to the Union Traction Company on December 1, on which date the superintendents and engineers appointed by General Manager Beetem will take charge of their departments. Since the consolidation the three systems have been practically operated by the old management under the general supervision of Mr. Beetem, and at present each company is buying its own supplies and materials and charging them against the Union Company, which is also credited with the receipts. After December 1 the Union Company will make all purchases and handle all receipts, though separate accounts will be kept for each of the three companies.

Syracuse, N. Y.—A company has been organized to build an electric railway from this city to Pleasant Beach on the lake, where grounds will be laid out as a park and furnished with all the attractions of the period. There will be among other things a bicycle track one-third of a mile long with a grand stand seating 3,000 people; observation tower, 400 feet in height, after the plan of the Eiffel tower; dancing pavilion, 150 by 150 feet; water toboggan slide, 250 feet in length; carousal building and wheel, with a carrying capacity of 100 people; music pavilion; electric fountain, modelled after the famous fountain at Fairmount park; Ferris wheel, 100 feet in height; scenic theater, etc. The whole park is to be lighted by its own electric plant. The officers of the company, just elected, are: President, A. T. Hoteling, Baldwinville, N. Y.; vice-president, John W. Truesdale, Syracuse; treasurer, Frank T. Miller, Syracuse; secretary, J. M. Price, Philadelphia; manager, A. E. Aldrich; promoter in chief, J. L. Dailey. The capital stock is $100,000.

Niles, Mich.—There was much rejoicing here over the opening of the Mahoning Valley Electric Railway. When the first cars arrived from Youngstown an impromptu meeting was held at the Sanford House, and several good speeches were made in which great things were predicted for the valley through the operation of the line. Hon. J. J. Sullivan, of Warren, paid a high tribute to John E. McVey, of Youngstown, and others connected with him in the building of the road, and evinced his pleasure in a jolly speech, saying among other things, that "ever since Raymond D. Sykes (a new arrival in Niles) was awarded the prize at the Canfield fair for being the handsomest baby in the Mahoning valley, I knew that Niles had a great future before it." Judge King, also, in a similar vein, showed how the advent of the trolley in a community connects itself with social interests of the most profound concern. "Something," he said, "had been mentioned about sparks. Now it seems to me that one good effect of the opening of this line will be to increase sparking. Young men will not have to pay livery bills and their horses eat pint oats, because they can call on the girls and get back home at any hour with little expense. So that for that reason the line is a good thing."

New York.—The Edison Electric Illuminating Company of New York reports gross earnings for October of $148,219, a decrease of $336 as compared with the same month of last year, and net $62,716, a decrease of $5,909. For the ten months ending October 31 the gross earnings were $1,469,376, an increase of $148,936 as compared with the corresponding period of last year, and net $708,433, an increase of $84,486.—The Metropolitan Traction Company has succeeded in leasing the Forty-second street and Boulevard surface line, and has also secured control of two other lines in the lower part of the city, which latter gives it the much desired connections with the ferries in the lower part of the city on the North and East rivers. The company will inaugurate a system of transit to and from the down town ferries, which will be feeders for its main lines, and will open up for the public an easy transit from the ferries to the different shopping centers of the city. A system of electric power will, it is stated, be used on these smaller lines.—The Kingsbridge street railway franchise was sold on the 14th inst. by Comptroller Fitch to the Third Avenue Railway Company for 38½ per cent. of its gross receipts over and above the three per cent. for five years and the five per cent. for the following five years required by law, and in addition the company gave to the city a bonus of $250,000. The franchise carries with it a provision that other companies shall have the right to use a certain part of the new route.—An explosion in the Brush electric light plant at 210 Elizabeth street, on Friday evening, threw many of the city's streets into darkness and caused considerable damage at the station. The cause of the trouble was the bursting of one of the main pipes leading from the boiler room to the engine room. None of the employees was injured.

TELEPHONE AND TELEGRAPH.

The Mutual Plan in New England.

George W. Coy, of New Haven, Conn., has just completed the organization of a new telephone company in Bridgeport and another in Norwalk. The Bridgeport exchange is to have 600 instruments and the Norwalk company have contracted for 136 telephones. In both instances the companies organized are mutual concerns and the maximum cost of the telephones are to be $20 a year for each instrument. It is stated that a number of business men of New Haven are awaiting the result of the Bridgeport venture, and if it proves a success a local rival to the Southern New England Company will be started.

Sold the Pole Lines For Taxes.

For some time past the Western Union Telegraph Company has refused to pay its taxes in several of the towns of Orleans county, N. Y., on the ground of excessive valuation. The county treasurer put up the company's property at auction and sold it to William A. Parmelee. The effects consist of standing poles and wires in use.

The Milwaukee Telephone Users' Association has elected permanent officers as follows: President, Eugene S. Elliott; vice-president, E. H. Bottum; secretary, Frank M. Hoyt; treasurer, David Adler. The association will continue its fight for lower rates in that city.

The Merrill Telephone Company, recently organized at Merrill, Wis., has let the contract to put in a telephone exchange to the Standard Telephone and Electric Company of Madison. The contract calls for the completion of the new exchange by December 10.

An ordinance is now pending in the common council of Hoboken, N. J., which if passed will give the Citizens' Telephone & Electric Company of that city subway rights on most of the important streets.

A tax of 25 cents per pole has been imposed upon the electric light, telephone and telegraph companies of Jacksonville, Fla. The companies will combine in a fight against the tax.

W. S. Rowe, manager of the Missouri Mercantile Telephone Company, has taken charge and will complete the construction of the new exchange at Pierre, S. D.

The International Telephone Company, Chicago, has made an assignment to Lynden A. Seymour. The liabilities are about $1,500 and assets nominally the same.

Marshall & Tobie will at once begin the erection of a telephone exchange at Keithsburg, Ill., having secured the requisite number of subscribers.

The Trenton Telephone Company, Trenton, Mo., will improve its exchange by the addition of a new switchboard and new 'phones.

The Northwestern Telephone Company of Milwaukee, Wis., is seeking a franchise to operate a telephone exchange at Racine, Wis.

A telephone exchange company is being organized at Newberg, Ore., by Gen. A. C. Parkinson and John Lamont.

James M. Lemon, of Minneapolis, Minn., has asked for a franchise to construct a telephone exchange at Orlando, Fla.

The DeKalb County Telephone Company is planning to construct a telephone line between Sycamore and Sandwich, Ill.

The town council of Fort Valley, Ga., has granted a ten-year telephone franchise to W. H. Harris and W. P. Harwell.

The Providence Telephone Company will erect an exchange building at Pawtucket, R. I., to cost $60,000.

The American Telephone and Telegraph Company has been granted a franchise at Kalamazoo, Mich.

The Iowa Union Telephone Company will extend its lines from Traer to Diwadle and Reinbeck.

Du Bois, Pa., is being canvassed to secure subscribers for a new telephone exchange.

New Companies Incorporated.

The Bluff City Telephone Company, Trempealeau, Wis. The incorporators are: Dr. B. A. Corneille and Clarence S. Utter. The object of the company is to build a telephone line from Trempealeau to Centerville, a distance of five miles, to connect with the Galesville line of Luce & Veitch, which also connects with the line of the Northwestern Telephone Company at Winona, giving a service to St. Paul, Chicago and the East.

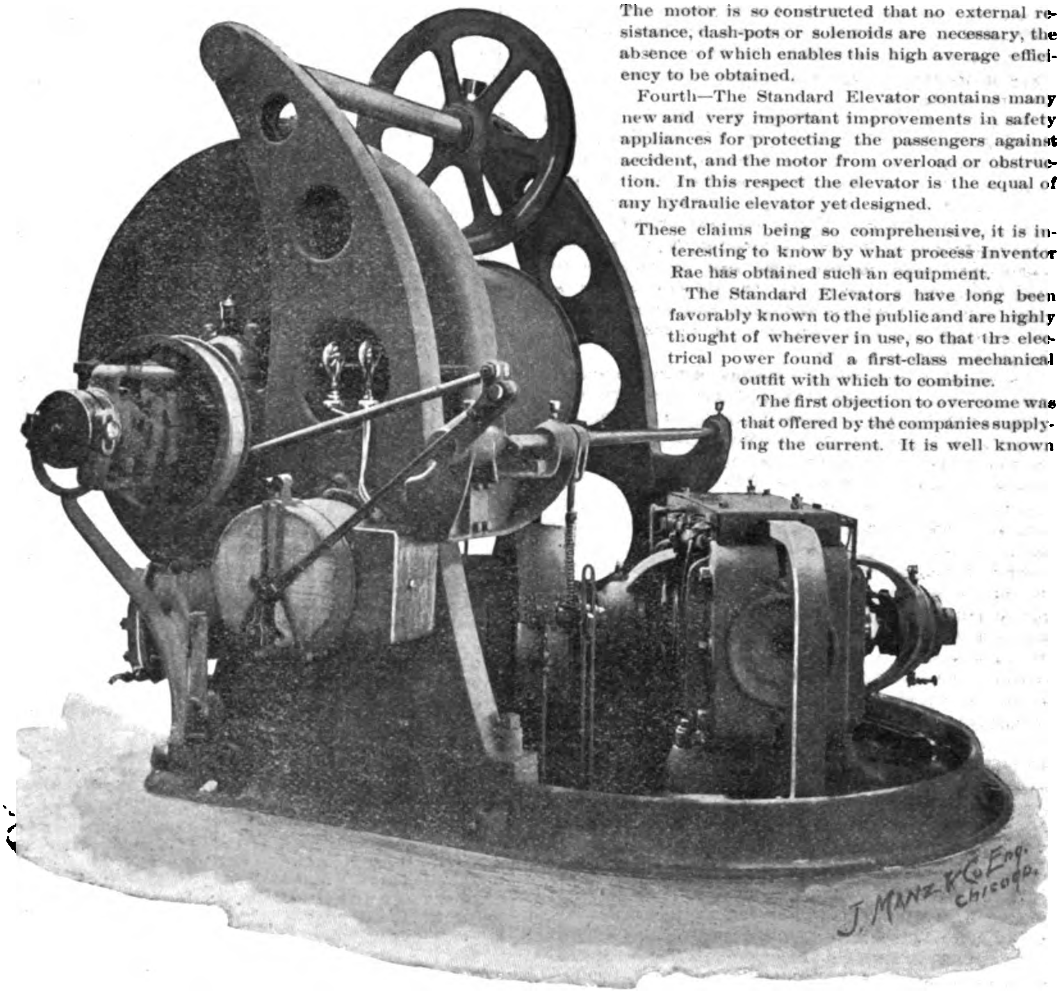
The stockholders of the Boyd's Telephone Company, of Rockville, Md., have elected these directors: Dr. J. E. Deets, Mahlon T. Lewis, Glen Poole, L. E. Price, Charles Waters, R. Barnes, Perry E. Waters, A. C. McCardell, R. K. Day, W. B. Burdette, and R. H. Bowman. The directors elected R. K. Day president, W. B. Burdette secretary, and Dr. J. E. Deets treasurer.

The Home Telephone Company, Alexandria, Va. Capital stock, $250,000. The officers are F. B. Hubbell, president; William L. Marbury, vice-president; James Russell, treasurer, and W. J. Atkinson, secretary and general manager.

The Western Telephone and Telegraph Company of Lima, O., has been incorporated with a capital stock of $25,000. Incorporators' names not given.

Standard High Duty Electric Elevator.

The adaptability of electricity to all service where power is required was never so apparent as in its application to passenger elevators.



STANDARD HIGH DUTY ELECTRIC ELEVATOR.

The modern elevator is one of the essential features of civilized society. Not only is it indispensable to all office buildings, but it is now considered a necessity in all hotels, club houses and houses of any pretension.

The many drawbacks of the hydraulic elevator, coupled with the great cost of installation and maintenance, has limited the field of the elevator up to date, but the success of the electric hoist seems destined to develop a field the extent of which has not yet been calculated.

The essential features of the electric elevator are (a) high speed, (b) absolute safety, (c) completely under control of operator, (d) applicable to the current to be supplied by the lighting mains, (e) low cost of operation and maintenance.

Each and all of these features are combined in the new electric elevator recently placed on the market by the Standard Elevator and Manufacturing Company of Chicago. The electric design is by Frank B. Rae, the well-known electrical engineer.

One of the reasons for the limited use of electricity in elevator work up to the present time is that elevator manufacturers have paid little or no attention to the design of the motor. In nearly all cases they have purchased an ordinary motor of some standard type from one of the electrical companies, and by the use of external resistance and complicated switches, controlled by dash-pots and solenoids, have operated a winding drum with more or less success.

Of course this clumsy construction would lift the load, start and stop the car, but it was highly inefficient as an elevator engine, and subject to the annoyances of stoppage, breakdowns, etc., inseparable from such makeshift construction.

The Standard Electric Elevator bids for public patronage on some very broad and interesting claims.

First—The operator has complete control of the car. He can move the car the entire distance of its travel at any speed irrespective of its load. At the same time the design of the motor is such that he cannot damage things by carelessness or a wilful manipulation of the controlling lever.

Second—The car starts immediately upon moving the lever, reaches maximum speed quickly and without jar. This is a feature of vital importance, as it enables the motor to assume a full load without the delay incident to all other types of electric elevators.

Third—The car *starts* with its maximum load, and secures a *high average efficiency*. As the percentage of total energy expended throughout the day in an electric elevator system is greater for starting the car from rest than in moving it at full speed, this is a matter of the first importance to the owner, who has the cost of operation to meet. The motor is so constructed that no external resistance, dash-pots or solenoids are necessary, the absence of which enables this high average efficiency to be obtained.

Fourth—The Standard Elevator contains many new and very important improvements in safety appliances for protecting the passengers against accident, and the motor from overload or obstruction. In this respect the elevator is the equal of any hydraulic elevator yet designed.

These claims being so comprehensive, it is interesting to know by what process Inventor Rae has obtained such an equipment.

The Standard Elevators have long been favorably known to the public and are highly thought of wherever in use, so that the electrical power found a first-class mechanical outfit with which to combine.

The first objection to overcome was that offered by the companies supplying the current. It is well known that the Edison companies refuse to permit more than 25 amperes of current at 220 volts to be drawn from their mains at any one instant, as a greater strain would seriously interfere with the lights. Heretofore this has been obviated by the operator waiting until, by the cutting out of resistances, the 50, 60 or 70 amperes necessary to start the load is introduced into the motor. This involves considerable delay, in addition to consuming a large amount of energy that in the Standard Elevator is not required at all.

Mr. Rae solved this problem by designing a motor specially adapted for the work, that is, a motor having a field of very large magnetic carrying capacity that can be energized at starting by a very large number of ampere turns. Thus the starting torque is provided by an intensely strong field and a small current.

Heretofore the greater part of the 220 volts provided by the lighting mains to electric elevators has been wasted in external resistances, leaving but little for the motor. In the Standard motor, however, there are no external resistances whatever, but a large number of turns are provided, giving the required ampere turns for energizing the field naturally.

The safety devices are novel and effective. An automatic locking device on the electrical controller and switch prevents injury if the car is loaded beyond its rated capacity. Under this condition of overload it is impossible for the operator to increase the current, the locking device holding switch at the position of maximum lifting capacity of motor. This permits a heavy load to be raised at slow speed with absolute safety.

In case of the car meeting with an obstruction when running at high speed, such as a tight place in the guides, the controller device will automatically diminish the speed and increase the power applied, so that when the obstruction is passed the car will again accelerate independent of but under the control of the operator.

Another valuable feature is that in case the current ceases, owing to interruption by stoppage of generating plant, or break in the supply conductors, the controller at once assumes the starting position independent of the operator, so that should the current be suddenly turned on again it finds the motor and appliances in condition to receive it without injury either electrically or mechanically.

Power Plant of the Niagara Falls Hydraulic Power & Manufacturing Company.

The hydraulic basin from which water is now taken for furnishing power to the various mills supplied with power by the above company, is located parallel to and about 300 feet back from the edge of the high bank of the Niagara River. For this new plant the water will be taken in an open canal from this hydraulic basin to a forebay 30 feet wide and 22 feet deep, which is now being built near to the edge of the high bank. From this forebay penstock pipes built of flange steel, 8 feet in diameter, conduct the water down over the high bank 210 feet to the site of the power house on the sloping bank at the edge of the water in the river below the Falls.

The building will be 60 x 100 feet, the intention being to add to the length of the building (60 feet) and place other wheels, fed by separate penstocks, from the same forebay as above as demand arises. There are four turbine wheels of the horizontal type, furnishing about 8,000 horse-power, to be located on the first floor of the power house. These wheels will work under a head of 210 feet, the highest head under which water has ever been used for power in the quantity proposed in this plant. The pressures exerted by water under this head are enormous, and every detail of the penstock and water wheels must be designed with the greatest care to hold it.

The penstock leads from the forebay vertically about 135 feet to the top of the sloping bank, thence down the slope to the side of the station next to the bank, making the total length of the 8-foot pipe about 240 feet. Into the building the pipe, 10 feet in diameter, runs horizontally, suspended over the tailrace. The thickness of the steel is fifteen-sixteenths of an inch. All horizontal joints are butt-strapped, held with three rows of rivets on each side. The cross seams are all double riveted. The necessity for strong work in this pipe will be seen when it is remembered that the total pressure on the end of the pipe exceeds a million pounds. From this horizontal portion of the penstock the water is taken directly up through 60 inch valves on to the water wheels, which are supported upon iron beams stiffened by braces into the side of the tailrace. The four wheels for this plant are being built by James Leffel & Co., of Springfield, Ohio, under general plans and specifications made by the engineer of the Niagara Falls Hydraulic Power & Manufacturing Company. Three of these turbines are specified to generate each 1,700 horse-power under a head of 205 feet, which is the minimum head estimated as obtainable, and to run at a speed of 250 revolutions per minute. As the ordinary head will be from 240 to 215 feet, the power of these wheels will be from 1,800 to 2,000 horse-power each.

The turbines are mounted on horizontal shafts of the double discharge design. These large turbines are fitted with runners 74 inches in diameter, made of extra quality of bronze metal, fitted with balance gates. The turbines are so designed that the wheel runners are absolutely balanced, due to the equal discharge of water on each side, thus doing away with all end-thrusts on the shafts. The wheels are fitted in cases 11 feet in diameter, made of best heavy plate steel, double riveted. The feeder pipe connections to these large cases are on the bottom of same, being riveted directly to the 5-foot hydraulic cylinder valves. All these valves are connected to the main feeder pipe, which is 10 feet in diameter, and occupy the space under the turbines between the foundation walls. The draft tubes from the turbines pass down each side of the main feeder pipe, connecting with the tail water, which is set at a distance of 27 feet from the center of the turbine shaft.

W. C. Johnson, of Niagara Falls, chief engineer of the company, is in charge of the plans for this work.—*Canadian Journal of Commerce.*

INCORPORATIONS.

The Electric City Malting and Brewing Company, Niagara Falls. Capital stock, $125,000. Directors: J. S. Macklem, C. F. Hathaway, A. C. Buell, and F. L. Lovelace, of Niagara Falls.

Hayes-Tracy-Fyfe Company at Chicago—to manufacture electrical devices. Capital stock, $30,000. Incorporators: Jamas Hayes, Edward C. Tracy and Herbert A. Schyver.

The Sheboygan Lamp Company, Sheboygan, Wis.—to manufacture electric lamps. Capital stock, $10,000. Promoters: J. Donahue, W. C. Johann, J. E. Collins, Sheboygan.

The Leechburg Electric Light and Power Company has been chartered at Harrisburg, Pa. Capital, $16,000.

The Columbian Construction Company, Clarksburg, W. Va.—to construct and operate ice, cold storage, electric light, gas and water plants, etc. Capital stock, $500 minimum, $5,000,000 maximum. Promoters: H. T. Miller, J. H. Johnson, Washington, D. C.; Fred. Balcolm, Jacksonville, Fla.; Fred C. Suter, Philadelphia.

The Philadelphia Electrical Equipment Company, Philadelphia. Pa.—to manufacture and sell electrical machinery and devices necessary and useful in the erection and use of electrical apparatus. Capital stock, $50,000. Promoters: Matthew A. Rettew, James R. Rettew, E. T. Watts, Philadelphia.

The Susquehanna Construction Company, Baltimore—to develop a water power on the Susquehanna River, near Conowingo, and generate electricity there for transmission to Baltimore and elsewhere. Capital stock, $100,000. Incorporators: J. Wesley Kerr, Otto J. Fisher, John Henry Miller, George K. McGaw and Fridge Murdock, who, with Edward J. Silkman and George W. Haulenbeck, comprise the board of directors.

Articles of agreement and consolidation have been filed of the St. Louis, Siloam and Southern Railroad Company of Missouri, and the St. Louis, Siloam and Southern Railroad Company of Arkansas, under the name of the St. Louis, Siloam and Southern Railroad Company. The consolidated company has a capital stock of $8,000,000

The North End Street Railway Company, New York—to build a street railway thirteen miles long, beginning at the junction of Manhattan avenue and 116th street and ending at the junction of Kingsbridge road and the northerly line of the city. There will be several branches. The directors are Daniel H. Shea, Thomas J. Regan, Pierre Jay, Frank F. Ogston and William C. Shailor, of New York; Edward K. Lynch, William D. Davis and Thomas E. Laughlen, of Brooklyn, and Charles H. Sisson, of Mount Vernon.

The Catskill, Cairo and Windham Street Railroad Company—to construct a street railroad, about ten miles long, in Greene County, from Catskill Landing to the village of Cairo, N. Y. Capital stock, $100,000. Directors: Louis E. Robert, Michael W. Conway, Wm. C. Wood, Daniel H. Gilligan, John L. Heins and Jacob Faber, of Brooklyn; Daniel Sharp, of Catskill, and S. Mattison, of Newark, N. J.

Articles of incorporation have been filed at Des Moines, Ia., by the Foreign Patent Company of Polk County, Ia. The capital stock is $15,000,000. The incorporators are Thursday Gordon Hall, Truman Hall, Robert H. Laird, all of Buffalo; William H. Laird, New York; Charles Turner Brown, Chicago. The company was organized for the purpose of handling patents issued by countries other than the United States for the manufacture, preservation and distribution of a fixed gas from carbonaceous material, steam and air with electric, catalyic or chemical action. Articles were filed at the same time by the same incorporators of the Rhode Island Electric Gas Company, having its headquarters in Polk County. The capital stock is $3,000,000. The company will sell the territory and construct plants for the patents of the parent company.

The West Side Suburban Water Company, Los Angeles, Cal.—to acquire water and water rights; construct dams, ditches, reservoirs, etc., for distributing water for irrigation and domestic purposes; operate machinery; generate electricity for supplying light and power. Capital stock, $2,000,000. Promoters: C. E. Brook, C. W. Buchanan, John McDonald, J. D. Cory, Pasadena, Cal.; W. S. Montgomery, E. C. Hine, James Kerr, Los Angeles, Cal.

The Contoocook Electric Light Company, Contoocook, N. H.—to operate an electric light plant in Contoocook and Warner. Capital stock, $10,000. Promoters: Walter S. Davis, G. A. Curtice, Horace I. Davis, George W. Paige, Amos A. Currier, Contoocook.

The Newark Consolidated Electric Railway Company (incorporated in W. Va.), Newark, Ohio—to construct railroads in Newark, Ohio, and operate them by electricity, etc. Capital stock, $500 minimum, $250,000 maximum. Promoters: Reinhardt Scheidler, J. A. Flor, John Schlagal, F. A. Crane, W. C. Christian, Newark.

The American Signal Company, Chicago, Ill—to manufacture and sell electrical and other machinery and appliances. Capital stock, $100,000. Promoters: Charles C. Arnold, Joseph P. Eames, John T. Bailey.

The Pacific Electric Company, Tacoma, Wash.—to manufacture, sell and dispose of electric lights and shades and other electrical apparatus. Capital stock, $2,000. Promoters: W. S. Dean, A. T. Espersen, Charles Bedford.

The Clay City Electric Light Company, Clay City, Ind.—to furnish the town of Clay City with electric light and power. Capital stock, $5,000. Promoters: Wm. Parsons, Chas. F. Nickey, Benj. M. Guirl.

The Oregon Electrical Construction Company, Portland, Ore.—to build, operate and maintain telegraph and telephone lines between Portland and Astoria, Oregon. Capital stock, $20,000. Promoters: G. F. Heusner, F. C. Miller, J. S. Urquhart, Portland, Ore.

The Pacific Water Company, Kings City, Cal.—to deal in real estate; develop and pipe water for domestic and irrigation purposes; establish plants for electric lights for all purposes; construct and run street cars. Capital stock, $300,000. Promoters: Wm. E. Ward, Benj. S. Coppock, E. Coppock, H. V. Morehouse, A. L. Burbank, San Jose, Cal.

The Sierra Development Company, Sausalito, Cal.—to deal in lands, goods, wares and merchandise; construct and operate mills for working ores; construct reservoirs, dams, ditches, flumes and pipe lines for distributing water for power; agricultural, mining, electricity, or other forms of power. Capital stock, $250,000. Promoters: M. F. Hudson, Oakland, Cal.; E. H. Rixford, T. B. Keret, H. C. Campbell, San Francisco; O. C. Millet, Sausalito, Cal.

The St. Joseph Railway, Light, Heat and Power Company, St. Joseph, Mo.—to build and operate street railways, etc. Capital stock, $3,500,000. Promoters: W. T. Van Brunt, R. A. Brown, J. R. Van Brunt, St. Joseph; W. M. Harriman, New York City.

The Lorain and Cleveland Railway Company, Cleveland, Ohio—to construct, operate and maintain a railroad to be operated with electricity between Lorain and Cleveland; generate electricity, selling the same for light, heat and power purposes. Capital stock, $500,000. Promoters: B. Mahler, E. W. Moore, E. C. Tillotson, S. H. Short, J. B. Hoge.

The Highland Railroad Company, New Albany, Ind.—to own and operate street or electric railroad in New Albany, to be operated by steam, electricity or other power. Capital stock, $25,000. Promoters: Henry Terstegge, John S. Shrader. Jacob Zinsmeister, Chas. Schwartzel, New Albany.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 12, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

549,485. Electric Locomotive. Francis B. Badt, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, same place. Filed Aug. 1, 1895.

549,580. Conduit-Electric Railway System. Byron E. Osborn, Auburn, N. Y. Filed July 14, 1894.

549,652. Underground Electric Propulsion. John E. Parker, New York, N. Y. Filed June 23, 1894.

549,655. Contact Device for Electric Railways. Constantin A. Philipsborn, Berlin, Germany, assignor by mesne assignments, to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed April 20, 189

ELECTRIC LIGHTS AND APPLIANCES.

549,577. Arc Lamp Globe Holder. Gilbert L. Moyer, Hartford, Conn, assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed March 19, 1895.

549,664. Apparatus for Heating and Lighting. Homer T. Yaryan, Toledo, Ohio. Filed Aug. 6, 1894.

549,724. Bracket for Incandescent Electric Lights. Wilber R. Hitchcock, Cornwall, Canada. Filed March 27, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

549,502. Dynamo-Brush. James Dickson and Robert G. Shapcott, London, England. Filed July 7, 1893. Renewed June 24, 1895.

549,422. Electric Motor System and Traction Device. Thomas P. Milligan, South Orange, N. J. Filed Jan. 26, 1895.

549,597. Combined Rheostat and Reversing Switch for Electric Motors. Jonathan P. B. Fiske, Alliance, Ohio Filed Nov. 6, 1894.

549,598. Electric Controller. Jonathan P. B. Fiske, Alliance, Ohio. Filed Feb. 13, 1895.

549,608. Electric Controller. William H. Morgan, Alliance, Ohio. Filed Aug. 22, 1895.

549,621. Controller for Electric Motors. Merle J. Wightman and Oscar Urban, Scranton, Pa. Filed Feb. 6, 1895.

549,636. Electrical Steering-Gear. George S. Grimston and Alfred H. Dykes, London, England. Filed April 9, 1895.

549,644. Regulation of Alternating Generators. Francis P. Ide, Eau Claire, Wis. Filed April 6, 1895.

549,874. Electric Speed-Regulator. Carl W. Larsor, Schenectady, N. Y., assignor of one-half to Walter N. Sheaff, Lynn, and Amond U. Jaasted, Boston, Mass. Filed April 8, 1895.

549,876. Electric Motor. Robert Lundell, Brooklyn, assignor by direct and mesne assignments to the Electric Experimental and Developing Company, New York, N. Y. Filed March 2, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

549,491. Railway Telephone System. William H. Clewley, Providence, R. I., assignor to William H. Nixon, same place. Filed April 10, 1895.

549,709. Multiple Telegraphy. Thomas B. Dixon, Henderson, Ky. Filed Sept. 12, 1895.

549,802. Telephone-Transmitter. Ignatius Lucas, Passaic, N. J. Filed May 15, 1895.

549,803. Telephone-Transmitter. Ignatius Lucas, Passaic, N. J. Filed May 31, 1895.

549,860. Telephone. Alfred Stromberg and Androv Carlson, Chicago, Ill. Filed Sept. 21, 1893.

MISCELLANEOUS.

549,501. Electric Shunting Device Augustus B. Depuy, Camden, N. J. Filed March 19, 1895.

549,542. Electric Elevator. Humphrey R. Smith, Chicago, Ill., assignor to the Winslow Brothers Elevator Company, same place. Filed March 4, 1895.

549,556. Automatic Electric Cut-Off. Clinton E. Whitney New York, N. Y. Filed Jan. 2, 1895.

549,715. Electric-Clock System. Adolf Franke, Berlin, Germany. Filed Sept. 19, 1893.

549,789. Automatic Danger-Signal Apparatus. Frederick Henius, Newark, N. J. Filed April 22, 1895.

549,794. Lightning and Heavy Current Arrester and Alarm. Miller R. Hutchison, Mobile, Ala. Filed May 25, 1895.

549,810. Electric Switch. William T. M. Mottram, Dallas, Tex. Filed July 9, 1889.

549,886. Electric Meter. Ralph O. Hood, Danvers, Mass Filed June 8, 1895.

EDITORIAL NOTES.

Conduit Electric Railway Activity. Although there has been comparatively little publicity attached to the subject, there is no doubt that for several months past the question uppermost in the minds of the larger manufacturing companies has been that of conduit electric railways.

The business of corporations is conducted very much as the business of individuals, and it is not to be wondered at that up to very lately these manufacturing companies have all been inclined to throw cold water upon the underground conduit business.

It is remembered that the Bell Telephone Company held back for a number of years any comprehensive long-distance service out of consideration for the Western Union Telegraph Company, which was a large holder of Bell Telephone Company stock. Probably the motives which have impelled the treatment of the conduit problem have been somewhat similar. The trolley systems were installed, business was growing rapidly, it was profitable, trolley securities were on the market in large quantities, and the introduction of a successful conduit system two years ago would no doubt have been an injury rather than a benefit to the manufacturing companies themselves. The continued and growing hostility to the overhead trolley, however, in large cities has no doubt convinced the manufacturers that sooner or later some one would come into the market with a successful conduit system, and there has of late been a decided awakening and a very lively effort among the riva companies to get control of and develop a practical system. It is now generally admitted that the solution of the problem will soon be thoroughly demonstrated.

ELECTRICITY has already commented on the system in use in Lenox avenue in this city and also in Washington, and the figures would seem to show that this system is out of the question on the ground of excessive first cost, whatever claims are made for economy in operation. It is equally true, however, that even this system is fully as practical as were the early Sprague and Van Depoele trolley systems. The General Electric Company may be said to stand committed to an open conduit, and it should be remembered that until very recently they have had in their employ, in the railway department, Mr. Walter H. Knight, who was one of the earliest advocates of the conduit system in this country, and it is probable that he has been giving more or less thought to this question ever since the absorption of the Bentley-Knight Company by the Thomson-Houston Company. We believe it is admitted, however, by the General Electric Company's best engineers that the open conduit costs at least $30,000 more per mile for construction than the best closed-conduit systems. Of course, however, first cost is not the only consideration.

The Westinghouse Company have taken hold of the problem in earnest, and believe that they have already got something commercial. and fit to sell, in their surface-contact system. This system would certainly not be extravagant in first cost for construction, and has the presumption of success in its favor.

The Siemens & Halske Company have had a system in practical use at Buda-Pesth for some years, and for the purposes of that city there is no doubt of its success. It should be borne in mind, however, that at Buda-Pesth on 27 miles of track there are only 60 cars used, which is a very different situation from that to be found in any city in the United States requiring a conduit system.

The Johnson-Lundell Company has recently been incorporated to promote the closed-conduit system which was chiefly the invention of Mr. Lundell. This has been in experimental use for some time, and has attracted much favorable comment. It is announced that Frank S. Hastings, one of the old guard of Edison men, has resigned as a director of the General Electric Company, and will devote the greater part of his time to the business of the Johnson-Lundell Company.

Beyond this, there are several inventors in the field with patents of more or less value. not yet disposed of. It is understood that the General Electric Company has purchased the Love patents, and it is believed that they are looking far enough ahead to take some interest even in patents for a closed-conduit system that they may be better in position to meet the competition of the Westinghouse, Johnson-Lundell, Gray and other more or less conspicuous systems.

One of the best-known engineers in the country has taken control, as a private speculation, of one of the newer systems, and his experience and judgment are known to be such that whatever he expresses public approval of would at least command respect.

There is no doubt that in the numerous crowded thoroughfares in our larger cities overhead trolley systems will sooner or later be abolished. Capt. Wm. Brophy, in an address printed in another column, takes the sensible view that if other wires are to be buried, trolley wires should be no exception. There is a fortune awaiting the company which first establishes beyond peradventure the success of an underground conduit electric railway. This can only be done by the equipment of a considerable length of road where the traffic is heavy, and by at least one year's operations. It is not conceivable that it will not be done. Who will do it? Who will be the first to reap the reward?

The Institute and The Storage Battery.

The most recent meeting of the American Institute of Electrical Engineers serves no less aptly to illustrate the growing interest in the storage battery than it shows the highly gratifying results to be obtained from a topical discussion of a live subject. There have been meetings of the Institute which have lacked as much in interest as in value, but the last was not one of these.

In the engineering and commercial fields of electrical development the storage battery is just now receiving that measure of attention which its importance and utility seem to demand. It is therefore both fitting and proper that the Institute, representing as it does the most advanced progress in the development of the art, should consider this timely subject.

There is much that the electrical public wants to know about storage batteries. Chiefest in importance is the question of cost. It is now the contention of storage battery advocates that for specific purposes, such as generating plant adjuncts, sub-stations, etc., there is economy of both first cost and maintenance in a storage battery equipment as compared with an all steam plant. To be convinced of the truthfulness of this statement the central station manager wants data upon which to estimate comparative cost for himself. A price per K. W. hour of output does not supply such information. In the calculations of the engine-dynamo central station manager or engineer the term "K. W. hour" but rarely enters. The K. W. is the unit of capacity upon which the cost of existing central station equipments has been estimated.

As assisting to avoid the confusion of the terms K. W. and K. W. hour of output, the remarks of Prof. Crocker are of value. He said:

> Most accumulators have a normal time of discharge of about 10 hours, hence the cost per K. W. hour is only one-tenth of the cost per K. W. of output, and this would, of course, vary with any change in the time of discharge. In many cases it is specious and leads to mistakes to speak of K. W. hours, to appreciate which fact we have only to realize that the K. W. hour capacity of a dynamo is almost infinite since it might run for twenty years. The actual K. W. of output, or in short, how many lamps can be simultaneously fed, is the question in electric lighting.

The storage battery situation has been cleared of the incubus of patent litigation; as an electrical apparatus the storage battery as now perfected is efficient and reliable. To extend the field of its applications, prospective users must be satisfied as to its commercial value. The discussion before the Institute is a good beginning in this direction.

One of the conspicuous features of this meeting and discussion was the exhibition of the changed views on the storage battery problem held now by technicists from those entertained and expressed two or three years ago. Few people cared then to discuss the question at all. It was regarded as a dead issue as far as any wide application was concerned. Now it is a live subject in which every practical man is interested and to the discussion of which he comes in a receptive frame of mind. There is no denying, moreover, that many converts have been made.

If the storage battery makers look for the reason of the general feeling of skepticism or direct hostility exhibited by the technical public in years past, they find it in their own acts, the conduct of their own business. Many of the unfortunate features of the situation in the past have of course been beyond the control of any individual concern, and have therefore been charged up against the business as a whole. The history is not so ancient but that it is fresh in everyone's mind.

A half dozen or so companies owned patents of various kinds. No one company had a monopoly on the score of patents or of skill, yet several had in them the possibilities of disturbance and of preventing any material progress in the art. Millions were spent and wasted in litigation and in experiments—continued misrepresentations were made by every concern in the trade, and the one which came nearest to success had the most patent suits to defend. All exhibited a dog-in-the-manger policy, and the results are on record.

At length all the patents of value and all the companies of any prominence are merged into one company controlled by a strong mind, and we now look for better things. It is easily within the bounds of truth to say that America is now producing as good a storage battery as there is in Europe. Europe is a large user of storage batteries. Up to a year ago it may be said America had not begun to use them. If they are found economical abroad, why not here?

The Institute discussion will go further to clear the atmosphere than would appear at first consideration. And we compliment the officers of that body upon their exquisite judgment in finally declining to throw out the paper of Mr. Nelson W. Perry. Mr. Perry's views on any subject are always interesting, and his wide experience, thorough training and achievements in this field entitle him to be heard. There is music in discussion, and the American public likes music. The brilliant success of the meeting was largely due to the reading of Mr. Perry's contribution.

Under the Searchlight.

Views and Opinions on Timely Topics.

Chinese to Learn Electricity.

China is about to establish a new foreign university at Tientsin, where science, civil, electrical, and mechanical engineering, mining, and law will be taught by foreign professors.

Is This True?

(From St. Joseph, Mo., Herald.)

The Philadelphia Electric Street Railway Company plans to run a number of unlighted cars over its lines "for the benefit of the girls who cannot receive their young gentlemen friends at home."

Seeking Better Prices.

Meetings of a number of electrical contractors, supply dealers and members of the Building Trades' Council have been held in both Buffalo and Chicago to develop a plan looking to the interests of skilled workmen, the securing of better prices, and arrange for some satisfactory basis on which bids could be made. It was decided to appoint a committee of three to meet a like committee from the Building Trades' Council to draw up resolutions which might be of service in this matter, and this report will be made before a larger meeting of those concerned.

Electric Light and Art in Europe.

Electric lighting is to be applied to art in Brussels. On the Anspach memorial St. Michael is represented on horseback slaying the dragon. The sword will be made to blaze like a sword of fire, lights will be put in the saint's eyes and inside of the dragon.

"INSULATION OF OVERHEAD AND UNDERGROUND CIRCUITS HAVING A DIFFERENCE OF POTENTIAL OF 2,000 VOLTS AND OVER."*

BY CAPT. WM. BROPHY.

As you all know, the State Legislature passed a law applicable to the city of Boston, compelling the owners of all electric wires within a certain prescribed district to place them underground prior to the first day of January, 1900. This includes electric wires of every name and nature, with the single exception of the overhead trolley of the West End Street Railway Company. To the average man, the reason for this exception on the part of the body that sits under the "gilded dome" seems inexplicable. For my own part, I have never been able to fathom the motives that control the actions of our legislators at different times, and as a matter of fact I deem my life too short to attempt to do so. It is plain to me that if the electric light, power, telegraph, telephone, fire and police wires are dangerous enough to be removed from poles and other structures, and placed under the surface of the street, the bare trolley should find a similar resting-place.

Capt. Wm. Brophy.

If, as it is assumed, the aim and purpose of this law was to add to the safety of the public, by removing what is considered a serious menace thereto, it falls very far short of its purpose when it permits this class of wires to remain above the earth while all others are placed beneath it.

I now come to the question of the insulation of the wires for high potential circuits.

My earliest recollection of arc light dynamos dates back to those of one-light capacity, with a difference of potential of from 30 to 50 volts. No attempt was made at that time to run two or more lamps in series. After the lamp was improved so as to make it possible to operate several of them in series, the capacity of the dynamos was gradually increased from 1 to 5, 10, 15, 25, 30, 50, 60 and 65 2,000 candle-power lamps at 50 volts and 10 amperes, or 500 watts, increasing the difference of potential at the brushes or switchboard from 50 volts to 3,250, this being exclusive of the energy required to overcome the resistance of the wire, connections, etc.

For some years no attempt was made to increase the capacity of arc-light dynamos beyond 65 lights. Quite recently, however, 125-light dynamos have been constructed and put in operation. This means a difference of potential of 6,250 volts, independent of the resistance of the rest of the circuit.

I have thus far dealt with constant current dynamos and circuits wherein the difference of potential varies with the number of lamps in the circuit. But as you all know, we have to deal with the primary circuits from alternating dynamos as well, in which is maintained a difference of potential throughout their entire length of from 1,000 to 2,000 volts. While the voltage in this class of circuits does not increase with the increase of the capacity of the dynamos from 650 to 8,000 and 10,000 lights, yet this increased energy is sufficient to afford ample food for thought to those on whom devolves the duty of so insulating such circuits as to reduce the loss of energy to a minimum and prevent accidents to persons and loss by fire.

---

*Abstract of paper read before the Electric Potentials Boston, November 25, 1895.

The same insulating supports, and practically the same insulating covering of the wires, that were used for overhead circuits of five arc lights are used on circuits of 125 lights at the present day. The same style of glass insulator that is used for telegraph circuits is used to-day for arc light circuits, with a difference of potential at the dynamo of between 6,000 and 7.000 volts, and for constant potential circuits with a difference of potential of 2,000 volts throughout their entire length.

The insulating covering of the wires differs in name only from that first used on the small 5 and 10 light circuits. That the insulation of high potential circuits has not kept pace with the increased amount of electrical energy maintained therein, no one can deny, and it is self-evident that perfect insulation will result in increased profits to electric light and power companies and increased immunity from loss and personal injury to the public.

How can this most desirable end be best attained? This is the problem to be met and solved. The manufacturers of lead-covered insulated wires and cables have succeeded in producing an insulation that meets the exacting requirements of the Boston Wire Department, viz., 20 megohms per mile per 100 volts. There is not an underground wire or cable used on high potential circuits in Boston the insulation of which does not exceed this; but the question of how long this high grade of insulation can be maintained is yet to be determined. The almost perfect insulation of underground wires and cables has already been accomplished, and the question now to be met and answered is, can the same grade of insulation be secured for overhead circuits?

My answer is, yes, if the same grade of insulation is used, and no, if the present grade of insulation and construction is continued. If the same grade of wires used in the underground circuits is used, however, I would not advise any one to adopt this plan, as the proper place for such conductors is underground; and while the cost when compared with that of overhead construction is very great, the amount of energy saved, that is now lost, would, I believe, pay a handsome dividend on the money invested, to say nothing of the immunity from loss and injury of the community and the absence of vexatious damage suits.

I believe that all high potential circuits should be placed underground, and I believe it can be done with ultimate profit to their owners.

But we have, and I fear will continue to have for some years to come, overhead circuits, and I come now to the question of how to construct and insulate them.

I hold that all high-potential circuits should be supported on wooden poles and cross-arms, and the wires of all low-potential circuits excluded from such poles; and I do not believe it best to place such wires on fixtures placed on roofs or other portions of buildings, but if they are so placed, they should be beyond the reach of persons standing or working on the roofs.

I believe the so-called insulating covering in use at the present time for high-potential overhead circuits to be worse than a delusion and a snare. I believe it would be better to hang out the danger signal at once, by using bare copper wire, than to continue the use of this flimsy fraud that affords no protection to human life or property, but lures innocent people on to injury and death. Knowing the worthlessness of the material, it becomes necessary to use the best form of insulating supports. The present style of glass insulators is not what is required. Many of these insulators are only so in name. The very best grade of glass or porcelain should be used, and the double or single petticoat pattern, the form best suited to the purpose being that which will offer the greatest amount of dry surface between the wire and the supporting pin. These insulators should be supported on wooden pins.

Iron poles on any part of high-potential circuits should not be tolerated in any civilized community. They are a relic of barbarism that should be relegated to the scrap heap, and any attempt to patch them up only serves as a thin disguise to the danger that lurks within them. Twenty-five to forty feet of wood between the iron and the ground means that much insulation, while one hundred feet of iron only means what the glass insulator, wooden pin and cross-arm afford. The waste of energy due to the iron poles on the long circuits, on which are placed 125 iron lamp poles, is simply enormous—so great that in rainy weather such circuits have to be cut in halves in order to send sufficient current through the lamps.

Where such circuits are placed on the modern iron and steel structures they become a source of danger to persons who have occasion to handle these or other wires on the same or other fixtures.

Such circuits should not be run between the branches or through the foliage of trees, but when it cannot be avoided, the highest class of insulated wire should be used, and this encased in lead or iron. Any attempt at protecting this insulation from abrasion by covering it with tape or cotton braid is useless.

All that I have said up to this time applies with equal force to direct and alternating current circuits; but there are certain features of the latter that require separate treatment.

As you know, a difference of potential of one. two or more thousand volts exists throughout the entire length of the primary circuit and between it and the earth, so that the danger from derived circuits to ground or from one side to the other is the same at a point one or more miles distant from the dynamo as it is at the brushes. Again, it is necessary for electrical and other reasons to run the wires in parallel and close together, in order that no other wires can be placed between them, and for convenience in making connections to the different transformers. Workmen and others can hardly pass between them without coming in contact with both of them, and for this reason I consider them far more dangerous than high potential series arc light circuits. As before stated, the covering of these wires affords little or no protection to those persons in dry weather, and none whatever during or immediately after rain storms.

If these circuits are to remain above ground they should be separated so that both cannot be reached at the same time by any person; but this would involve the changing of nearly every existing circuit and a considerable increase in the cost of constructing new ones. Rather than adopt this plan, a high grade of lead-covered insulated wires should be used, and when that is done the proper place for them is underground.

The transformers should be placed beyond the reach of every one, and the primary wires that lead to them. The best way to do this is by placing the former in a stout wooden box, kept securely closed and well ventilated, and using high grade lead-covered insulated conductors.

I believe the time is coming when all these circuits will be placed underground, and the transformers also. Instead of placing the latter on the outer walls and roofs of buildings and in some portions of their interior, they will be placed in suitable vaults beneath the streets and sidewalks, and each one will be of sufficient size to supply a large number of lamps or motors.

The danger to life from high-potential circuits comes from two causes—establishing a derived circuit from any one point thereof through the person to the ground and from the ground to some other point of the circuit, or by closing the circuit through the body.

The danger from fire is mainly due to imperfect insulation.

The placing of the wires of alternating circuits underground removes one source of danger, but adds another not heretofore considered. On such circuits a second ground is not necessary to injure or kill a person who accidentally connects any portion of one of these circuits to the ground through himself. A person standing on or touching with one hand an iron pole, and with the other a bare or poorly insulated wire, or the iron case of a transformer that is in contact with the primary coil contained therein, will, owing to the failure of the insulation, surely receive a severe or fatal shock, although the circuit be perfectly free from "grounds." The reason for this is that the copper conductor is one, and the ground the other, plate of a condenser; and these plates readily discharge through any path of low resistance that is offered from one to the other. This, unlike the Leyden jar, is continually charged, owing to the alternations of the current; and the energy thus produced passes through the body of the unfortunate person who forms the connection from wire to earth, and vice versa.

To this cause may be laid the loss of one life at least; and in this case the circuit on which the accident occurred was clear of "grounds," with the exception of the one established by the unfortunate victim through the medium of an iron pole on which one of his hands rested while the other grasped one of the primary wires leading to the idle transformer.

Tests of the circuit just previous to the accident proved it to be clear of any preceptible leakage to ground. This fact having been established, the question of how this man lost his life had to be answered. This answer was rendered after the following test had been made: A known resistance was inserted in a wire, one end of which was connected to ground, while the other was connected to one side of the circuit. The electromotive force was measured by means of a Weston voltmeter, and it was found that a sufficient amount of energy passed over the wire and through this resistance to instantly kill.

From this you can see the necessity for the best possible insulation of the wires of these circuits and the greatest care in placing transformers, in order to prevent a recurrence of similar fatalities.

I will close by expressing the hope and wish that this club—a semi-scientific organization—will never hesitate to warn the public of any real dangers that may exist in connection with the transmission of electrical energy. I consider it a crime to lull the public into a sense of false security. It is equally one to needlessly alarm it.

American Institute of Electrical Engineers.

There were 115 members and guests at the 101st meeting of the American Institute of Electrical Engineers on the evening of the 20th inst. The evening was devoted to a topical discussion of "Storage Battery Applications" which was as spirited and entertaining as it was timely and interesting. Communications submitted by A. E. Childs and A. L. Edgar of Boston, F. B. Crocker and N. W. Perry of New York and Carl Hering of Philadelphia formed the basis of the discussion, which was participated in by H. Ward Leonard, E. T. Birdsall, J. B. Entz, J. Appleton, C. Blizard, Townsend Wolcott, J. W. Lieb, Jr., and others. This was the first experience of the Institute in the line of topical discussions and the result in New York was highly gratifying. President Duncan deemed it advisable to call for an adjournment at 11 o'clock, though at that hour the participants were quite willing to prolong the discussion.

The subject was also discussed at Chicago and San Francisco the same evening.

G. E. EXPLOITING WORK.

OBJECT LESSONS—THE CHARACTER OF ESTABLISHED STATIONS.

CHAPTER III.

TRIALS AND TRIBULATIONS OF A G. E. CENTRAL STATION MANAGER.

Reports of the Superintendent of the Austin (Minn.) Station.

Austin, Minn., Nov. 30, 1893.

Geo. C. Duffie.

Dear Sir: Replying to yours of November 25, will say I saw Levis about my salary while in St. Paul and he said I could draw all that was due up to November 1st, but when I went to the cashier I found the check short for two months, because Johnson had me transferred to the Austin account. I have written Levis about the matter and up to date received no reply. We have had so much trouble of late, I could find no time to take up the subject of pumping the water. Will do so just as soon as possible. Hope the company will either pay my salary or discharge me, and I care but little which they do. *Johnson is a pusillanimous pup and dictator in that office*|

It was the understanding when I came here that my salary should go on the same at the N. W. office and on the pay roll of that company. I am still at work for the N. W. Co. by agreement and shall look to them for my salary. Any time however they wish to let me out, I have no protest to make and am willing to settle up and step out at any time. Very truly yours,

W. S. PIERCE.

Austin, Minn., Dec. 4, 1893.

Geo. C. Duffie.

Dear Sir: There are so many questions relative to this plant which ought to be considered, I have concluded to go to St. Paul Monday next, and hope you will remain in the city so I can meet you at the office. I think this plant ought to be relieved of my salary, and if the Co. can give me a satisfactory settlement I will hustle for myself. I am collecting and can not say more just at this time. Very truly yours.

W. S. PIERCE.

Austin, Minn., Dec. 5, 1893.

C. R. Hyde.

Dear Sir: It is all night and no day this way now. Our bank boards are here and this is the first night they have been in use. They work all right, and I hope the engineers will be able to run with these and not break so many lamps. By the old method the lamp breakage was terrific. We have borrowed about 12 tons of coal of the city, and have received two cars, 15 tons in each, making 30 tons in all. This you see will last but a little while, so there ought to be three or four cars more in the near future. As I have got my salary for November, I wish you would see if the N. W. Co. can credit my back salary for September and October on the books, or send me a note for the same, so it will not be drifting around loose. I wrote Levis but received no reply. Please forward the lamps as soon as possible, as we are running low. This all-night business is a hard proposition, during November and December at least.

Very truly yours, W. S. PIERCE.

Austin, Minn., Dec. 14, 1893.

C. R. Hyde.

Dear Sir: Please hurry up the shipment of carbons as we shall soon be out of all the good ones we have. *Also coal.* Our two 15 ton cars are played out, and unless we get more day after to-morrow we shall be forced to borrow again. We need 20 tons of coal every week now for the next six weeks. When we borrow Mount Olive and pay back in Wilmington we lose money. Tell Mr. Duffie I will take up the pumping proposition in the near future. The insurance company's man is here inspecting our boilers. Have scalded my hand and can not write so that it can be read. Very truly yours,

W. S. PIERCE.

Austin, Minn., Dec. 14, 1893.

C. R. Hyde.

Dear Sir: Enclosed please find bill of items on which I have advanced the money, together with the bills as vouchers for the correctness of the same. I have also advanced $60 freight on coal at this date, which I will hold till next month, inasmuch as we can not now collect our bill against the city. December will be a full month all around, then I will put in the bills for freight on coal. These small bills are partly for freight, and some belong to the street job, not gathered in before. Please send me check for this amount inasmuch as I am waiting longer on the coal bills. Yours very truly,

W. S. PIERCE.

Austin, Minn., Dec. 15, 1893.

C. R. Hyde.

Dear Sir: WE ARE STRANDED FOR COAL, and are borrowing again from the city. The water works use Mount Olive, and we have to pay back in Wilmington, ton for ton. This is a losing game, because Mount Olive burns like straw. Please fill us up with a hundred ton draft of coal, for this is the season in this business that takes a large amount during the month. We have ample storage room for 100 tons at one time, and December and January will take 80 tons each at least. *The moon has gone back on us,* because each and every night is cloudy, thereby forcing us to run street lights all the time.

Very truly yours,

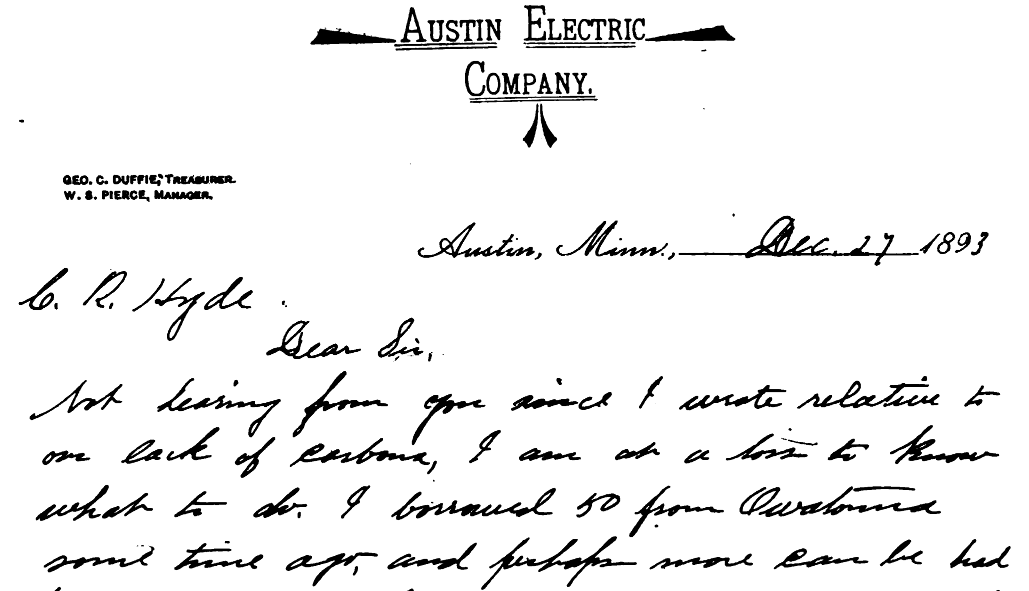
W. S. PIERCE.

Austin, Minn., Dec. 21, 1893.

C. R. Hyde.

Dear Sir: Unless the carbons reach us within the next three days, the arc circuit can not run. The 52 volt lamps are nearly all gone. Can not understand why it takes so long to get a shipment of carbons. The Co. I think had better throw up the sponge. Very truly yours,

W. S. PIERCE.



AUSTIN ELECTRIC COMPANY.

GEO. C. DUFFIE, TREASURER.
W. S. PIERCE, MANAGER.

Austin, Minn., Dec. 27 1893

C. R. Hyde.

Dear Sir,

Not hearing from you since I wrote relative to our lack of carbons, I am at a loss to know what to do. I borrowed 50 from Owatonna some time ago, and perhaps more can be had from that station. We can not run the arc lamps without carbons, and we have only just a few in stock. I can not understand the cause of the long delay. There are three things we can not get along without, that is coal, lamps and carbons. Please stir up the carbons and the 100 — 52 v. 16 c.p. lamps. What the electrical business is comming to is more than I can tell, but one thing is sure, firms here are so hard up that they kick on every bill, every meter, and many will throw up the sponge before the grass grows again. Let me hear from you by return mail as to the prospects. Very truly yours,

W. S. Pierce,

Austin, Minn., Dec. 28, 1893.

C. R. Hyde.

Dear Sir: Replying to yours of the 27th will say—We can get along till the 1st of Jan. with the 52 v. lamps we have, but such is not the case with carbons. The lamps should be ordered now, because we will have in another collection before they reach us, so they will not be waiting for the cash at all. This new idea about cash to my mind is strictly the business of the owners of this plant and not yours or mine. Perhaps the plan is to run on wind, however, unless we are able to create cash by smiting the rock of our wonderful resources with a pine stick and saying within our hearts, Cash, burst forth! Burst forth, cash! If there are any gods either great or small among the company who have this creative power, they are the blueberries who ought to be placed in charge here at once. The divine right of kings has been denied the present writer, and all I can do is to deposit all the cash collected and render a statement of the same. Here my power finds a limit. We now owe the city 34 tons of borrowed coal. We have this to pay and there are 30 tons on the track and 15 tons in the coal house. I shall use that on the track and pay the city when we get two more cars which I have ordered and which will be here soon after the 1st of January, so I might say we have 45 tons which are available. Beyond this we must rely on new orders. Well, friend Hyde, I can run on any policy outlined, either with wind or water, yet the runs are liable to enter the ground, and if so there is no room for a kick. Wishing you a happy New Year, I remain yours truly,

W. S. PIERCE.

Austin, Minn., Jan. 22, 1894.

C. R. Hyde.

Dear Sir: Enclosed please find receipted bills on which I have advanced the money up to date. All others I will turn over to Mr. Haskell, and these can be checked at some future time. Please send a check payable to my order for the inclosed vouchers, as I wish to turn over to Mr. Haskell a clean sheet.

Very truly yours, W. S. PIERCE.

Amount advanced $100.93.

The Standard Telephone Co.

MR. BARNES'S DEFENCE.

Continued Misstatements and Misrepresentations.

The Original Standard Prospectus.

We congratulate our esteemed contemporary, the *Electrical Review*, on its great triumph in securing from Mr. Thurlow Weed Barnes, president of the Standard Telephone Company, a "statement" in regard to the affairs of that company. It took the *Review* just one month and four days from the time ELECTRICITY made the original and conclusive exposure of this company's methods to get its courage up to the point where it dared to say anything; but it is better to be on the right side late than to be always on the wrong side, and our contemporary shows signs of some backbone at last.

ELECTRICITY welcomes all new recruits to the side of right, and accords to the *Electrical Review* the second place in the procession. This is honor enough.

Among the few things which Mr. Barnes says in his defence, we quote the following:

They say the Standard has no patents.

No responsible person will so assert, because the records of the United States Patent Office show to the contrary.

ELECTRICITY says again that the Standard Telephone Company has no patents of any value.

The records of the Patent Office are voluminous and complicated. The Standard Telephone Company would be dead before anything of this nature could be learned from the records alone. But it would not take Mr. Barnes ten minutes to give out the list—if he has it.

They say the Standard has no exchange in operation.

The Standard has an exchange in operation, and has had one for some time, at Kingston, N. Y., with over 250 miles of wire.

Mr. John H. Farrell, of Albany, one of the most prominent business men of the city, who is a director of the Citizens' Company, has stated to a representative of ELECTRICITY:

"The Standard Telephone Company has not, nor has it ever had, one dollar's worth of interest in the Citizens' Standard Telephone Company of Kingston."

They say the Standard Telephone Company has no manufacturing facilities and cannot supply telephones.

ELECTRICITY repeats the charge. The Standard Company has no manufacturing facilities to justify a capitalization of even $10,000.

They say the Standard has no switchboard.

The company refers to the written opinion of Myron Francis Hill, until lately examiner of patents in the United States Patent Office, who very summarily disposes of that canard. The Standard patents, Mr. Hill says, are "valid, fundamental and impregnable."

Mr. Hill has an *experimental* switchboard nearly completed in this city. It has not been tested. The question of patents is secondary, the main point being, will the switchboard work. Experts who have seen it say no. Mr. Hill is furthermore not an unprejudiced authority, but is an employè of the Standard Company.

They say that the Standard directors are bad men.

The same sheet that originated this allegation has for months been bringing the same charge against the directors of the General Electric, who are among the most prominent and honored capitalists in this country.

And if the Standard Company's investors fared no worse than the General Electric investors, every criticism is justified. Under ELECTRICITY'S exposures General Electric shares have fallen from 119⅞ to 25⅞. And we charge that Standard investors will fare much worse than General Electric investors.

They say the Standard telephone patents are valueless.

Marcellus Bailey, who drew the specifications for the original Bell telephone patent, says: "The Standard patents are as solid as the rocks of Gibraltar."

Mr. Bailey is also financially interested in the success of the Standard Company.

George William Moore, of Detroit, Mich., a very able lawyer, and General James McNaught, of New York, the great corporation lawyer, express the same opinion; so do other authorities, professional, expert and practical.

Mr. Moore is a one-third owner in the patents of Mr. W. R. Cole of Detroit, the Standard Company and Mr. Cole owning the other two-thirds. Who is the great corporation lawyer, Gen. James McNaught, who is now located in the Standard Telephone Company's offices?

A "wicked" circular, not dated, addressed to no one and unsigned, is said to have been issued by the Standard.

When asked if it were a fact, President Thurlow Weed Barnes, of the Standard Company, telegraphed to Philadelphia: "I never authorized nor issued such a circular, nor did the Board of Directors do so." When the same question was asked of General Clarkson, another official in the Standard, he said: "We never issued it. . . . We have gone into a big fight and expect a hard struggle, and this is part of it." Director R. W. Hunt, of Chicago, said: "No business man would issue such a circular." Director R. A. Parker, of Memphis Tenn., said: "The recent published attack upon the company did not, in any degree, weaken my confidence. . . . Your efforts deserve success, even if never attained."

The following letters remain unanswered:

[COPY.]

"ELECTRICITY,"
6 Park Place, New York. October 25, 1895.

HON. J. S. CLARKSON,
Fifth Ave. Hotel, New York.

DEAR SIR: I notice in a recent interview attributed to you, in the *New York Herald*, a denial of the authenticity of a Standard Telephone circular recently published in this paper, and would esteem it a favor if you will make such denial over your own signature, and forward to me.

Yours very truly,
(Signed) B. E. GREENE, Publisher.
(Dictated.)

[COPY.]

"ELECTRICITY,"
6 Park Place, New York. October 25, 1895.

THURLOW WEED BARNES, ESQ.,
President Standard Telephone Co., New York.

DEAR SIR: I notice that in interviews with various people connected with your company the authenticity of one of your telephone circulars, recently published in this paper, is denied, and I beg to advise you that you are at liberty to use whatever space in our columns is necessary to deny that the circular in question was prepared and issued by the Standard Telephone Company of New York.

Yours very truly,
(Dictated.) (Signed) B. E. GREENE, Publisher.

They say that the Standard does not own the McDonough patents.

The Standard does not depend for its existence upon the McDonough patents, but the Standard owns them amongst a great many others; the McDonough company is under the control of the Standard.

The Standard Company does not own the McDonough patents. It owns the controlling interest in the McDonough Company. The McDonough Company does not own the McDonough patents. It has a license under those patents for five States only. The Strowger Company of Chicago owns several State licenses also, and has already sold the territory of Philadelphia and New York City. It will cost any company more in litigation to decide who does own the McDonough rights in various localities than the patents are worth. Mr. Barnes knows this. So does Mr. J. Wesley Allison.

They say that certain prominent gentlemen left the Standard.

Since the formation of the Standard two or three gentlemen who intended to act with it withdrew. They are still stockholders in the company, however.

GRIFFIN WHEEL COMPANY.
Car Wheels of Every Description.
Chicago, November 18, 1895.

MR. B. E. GREENE, Publisher "ELECTRICITY,"
No. 6 Park Place, New York, N. Y.

DEAR SIR: In regard to yours of the 16th inst., I beg to state that I have no connection with the Standard Telephone Company, although I was at one time elected as a member of the Board of Directors. Not approving of their methods of handling their business I resigned. Yours truly,

T. A. GRIFFIN.

So much for Mr. Barnes and his statements.

When the Standard Company went into business a prospectus was issued which we will now proceed to analyze:

[COPY.]

STANDARD TELEPHONE COMPANY.
Main Office: 68 Broad Street, New York.
In effect, January, 1895.

That the telephone is a most useful device, which has achieved wonders in enlarging our means of communicating human intelligence, is a self-evident proposition. In the homes of the rich, and in many business offices and public places to-day, the telephone is regarded as a necessity. From a little experimental scheme at the start, telephony sprang into one of the most tremendously successful enterprises of which the present generation has cognizance; its growth has been fabulous, and the profits of the comparatively few who were believers in it from the beginning—well, no one knows exactly what they have been, but it is certain that they have far surpassed the most glittering dreams of all who had faith at the outset.

In alliance with the organizations named within, the Standard Telephone Company, organized in 1894, proposes to do a general commercial and domestic local and long-distance telephone and telegraph business in the United States of America and in other civilized countries.

The company owns invaluable telephone patents, a list of which will be furnished on application.

[Every man who bought stock in the State companies after this circular was issued has a legal right to *demand* a list of the patents.]

Rights of way and other privileges are owned and controlled in many of the States and elsewhere. Standard telephones are superior in every way to the Bell or any other instruments. Successful tests have been made with them over distances of more than 1,000 miles, and electricians give assurance that as soon as the experiment shall be tried, conversation can be carried on easily from New York to Denver, not to say San Francisco. Over practical resistances equivalent to more than 3,000 miles, tests have been entirely satisfactory.

The first essential for a great telephone business is an instrument of the first rank, commercially successful, and such an instrument is owned outright by the Standard Company.

[This is ELECTRICITY'S main contention, that the first essential for a great telephone business is an instrument of the first rank. This instrument and the patents on it, if any, should be shown to every man who asks to see it; secrecy in this matter is proof of weakness.]

As to its validity, reference is made to the head counsel of the corporation, George William Moore, Esq., Detroit, Mich. As to its vast commercial superiority and universal practicability, reference is made to A. T. Nye, Esq., of New York, General Manager, formerly General Manager of the "Overland Telephone and Telegraph Company," organized in 1881.

From "magneto" concerns the telephone monopoly has nothing to fear, nor has the public anything to expect. Without a telephone which is a real telephone in fact, as well as in name, no new company can enter the field. Upon an instrument capable of meeting every test in actual, practical service against induction and over thousands of miles of wire, no matter what the conditions of the atmosphere—upon such an instrument only can a new concern be founded, if that concern is to live and live successfully. These conditions are exactly those which the Standard is prepared to meet, and meet not as an experiment but with appliances whose practical value has been demonstrated.

Many men of prominence and large business ability are actively associated with the organizations in the Standard system. Their names carry weight, especially in their own localities, and are an earnest of the intelligence and capacity with which the business of these companies will be conducted. The names of directors of State concerns, and other organizations, are on file at the office of the parent company, 68 Broad Street, New York City.

For the better development and conduct of its business, the Standard Company has adopted the "home rule" principle. The whole capital stock of allied corporations is issued to the parent concern for licenses granted to exclusive operation in specified territory. Stock of all sub-companies is full paid and non-assessable. The Board of Directors of each State concern will consist of thirteen persons, and these organizations are virtually branches of the parent company, as the last-named is a holder of stock in each company formed. The parent company agrees to defend all its patents. The business of State companies consists in the sale of territory and the organization and installation of local companies.

Too great caution cannot be exercised in entering the telephone field, to secure an instrument that is not only commercially and practically a demonstrated success over long distances, against induction, and in spite of any climatic condition, but is non-infringing. Since the expiration of the Bell patents, numerous telephone companies have been organized or are in course of formation. The only one of these which has made any headway stole one of the Standard's assets, and another patented asset from the "Bell." Suit has been begun, and they will be compelled to close out their business. There are only five known efficient telephones, two owned by the Bell Company and the three owned outright or controlled by the Standard. All other 'phones are infringements on these patents. The Standard Telephone Company has already been approached by several new organizations for licenses to use Standard 'phones, and as soon as our various State Companies' Boards have been organized, they will get all the business they care to handle, as people throughout the whole country show a determination to emancipate themselves from the present unpopular monopoly. It is proposed by the Standard to put rates at figures that will bring the telephone within reach of every store, shop, and office, and of every private family. To-day the telephone, like a horse and carriage, is a luxury which only a limited few can enjoy. Look, for example, at Brooklyn, a city of one million people, and less than 4,800 telephones in use! The business is in its infancy, and the Standard telephone is the best ever made. Resting for its superiority on the broad principle of the immediate application of electric power (the company owning this ground patent), the Standard telephone is absolutely certain, original, satisfactory and instantaneous.

In an enterprise where large responsibilities and undertakings are entered upon, it is well to look advisedly in the first place upon the question whether the undertaking is built upon fair business lines, and with a reasonable prospect of successful management and operation, and in the next place upon the question as to whether the men connected with the undertaking are men upon whom may be placed a large measure of public respect and confidence.

[If the above advice had been followed, not one dollar of money would have been paid for State rights in the Standard Company.]

The proposition that the telephone field is open, on account of the expiration of Bell patents, is not in any wise in question. The proposition that the Standard Company has instruments of enormous value, the superiority of which to all others is, in the opinion of experts, very marked, is also impregnable. These form the practical materials with which the Standard begins its career. As to the method in which the Standard proposes to operate, and the character and position of the men who constitute the new company: (1) The business will be carried on as explained in each locality by allied companies, under the control of local managers. For the purposes of the parent company, whose operations will be by no means confined to the United States, the world is parcelled out under upwards of twenty organized local corporations, each holding exclusive licenses to employ Standard devices in certain specified territory. (2) Herewith are given the names of the directors of the Standard Telephone Company, parent concern, and the names of twenty allied corporations, each of which pays for its license by the deposit of a certain portion of its capital stock in the treasury of the parent concern, with the territory and capitalization of each sub-company, and its principal place or places of doing business.

Full understanding of the position and intentions of the Standard Company can best be furnished by a glance at these pages, supplemented by a list of the men who are associated with each allied corporation.

The above prospectus is printed at this time to show the details of the plan. It is nine months old. Will Mr. Barnes please announce what steps he has taken to give stockholders any action on their money?

At Richmond a franchise has finally been granted by the common council to both the Standard and Home companies, with no exclusive privileges to either. The matter now goes to the Board of Aldermen where it will be finally settled.

LEGAL NOTES.

The Northwestern Electric Light and Power Company of Omaha, Neb., has brought suits against the New Omaha Thomson-Houston Electric Light Company and the Omaha Illuminating Company, in which damages amounting to $55,500 are claimed for infringement of the terms of a lease.

The Superior Court of Colorado has rendered a decision affirming the judgment of a lower court which awarded $2,800 to a man who had brought suit against the Consolidated Electric Light Company of Denver for damages sustained from accidental contact with a live wire. The court held that a corporation engaged in distributing electricity was bound to exercise extraordinary care and caution, its obligation in that regard exceeding that of a common carrier because of the dangerous character of the business.

In the quo warranto case of the Springfield Electric Light and Power Company vs. the City of Springfield, Ill., questioning the right of the city council to pass the ordinance granting the Capital Electric Company a franchise and contracting with them for lighting the city on the ground that it was contracting an indebtedness beyond that authorized by law, Judge Creighton decided the case in favor of the city, and the appellate court sustains the decision of the lower court.

A writ of certiorari has been sued out by the Edison Electric Illuminating Company of Brooklyn, to review the tax assessment on its personal property. Its assessed valuation last year was $304,000, and this year it has been raised to $1,070.650.

From Brush to Rail.

THE COURSE TAKEN BY THE ELECTRIC CURRENT IN PROPELLING STREET CARS.

Passengers on electric street railways know in a general way that the generators in the power house produce the current; that the trolley takes it from the wire and the motor underneath propels the car along over the street. Every motorman in charge of a car knows that by moving the handle of the controlling switch from point to point a successive gradation of speed of the car can be attained. But there are comparatively few motormen, and still fewer passengers, who understand or can clearly explain the functions and operation of the devices used in the operation of a car.

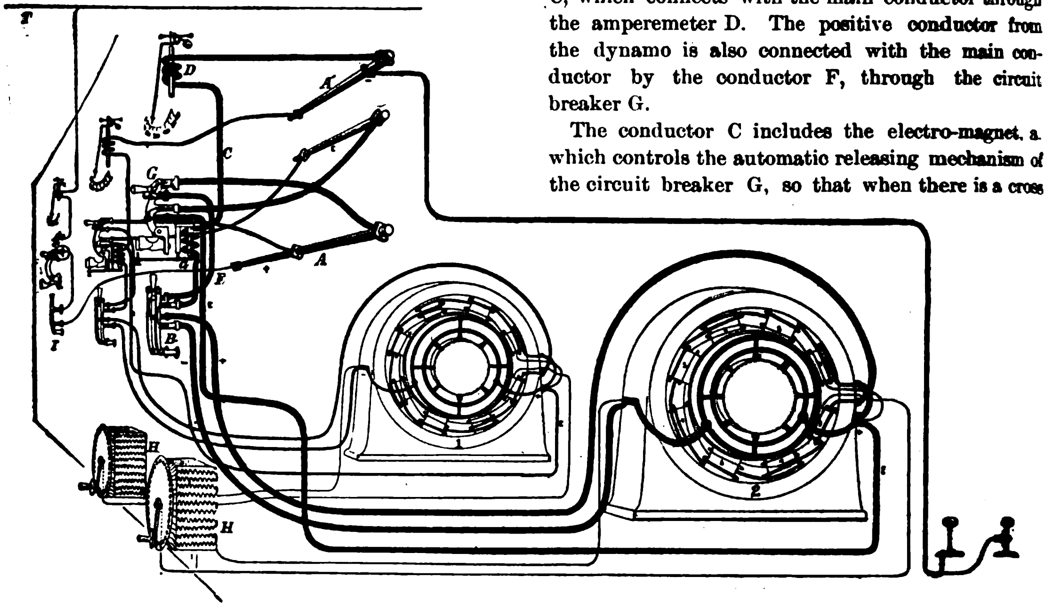

FIG. 1.—GENERATOR AND SWITCHBOARD CONNECTIONS.

In some recent numbers of the *Scientific American* here was published an illustrated description of the generating plant of the Fair Haven and Westville electric road, which was supplemented by a number of diagrams and descriptive text, both reproduced here, which will be of material assistance to all those wishing to become better informed upon the details of the electrical propulsion of street cars.

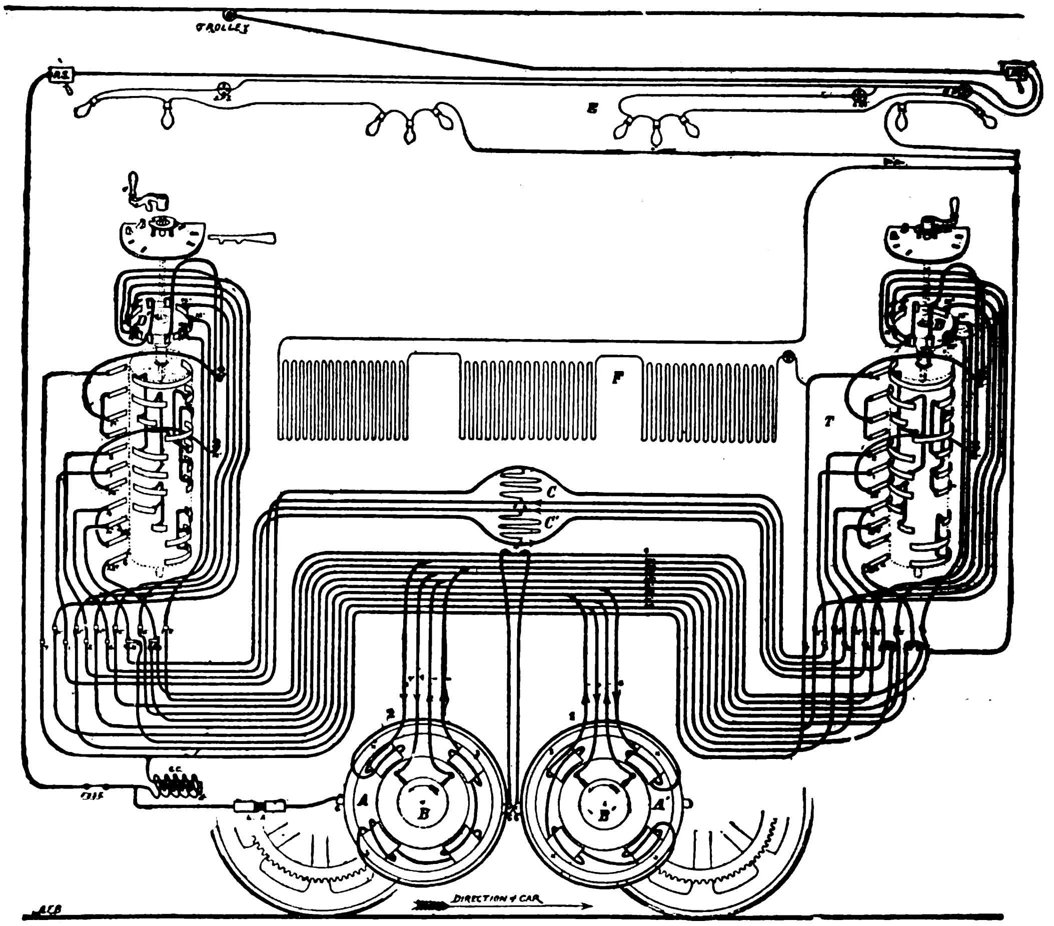

FIG. 2. —TROLLEY AND MOTOR CONNECTIONS.

In Figure 1 is shown the switchboard connections of two generators. A represents the positive main conductor and A′ the negative, while E E are the equalizing conductors from the two dynamos, the positive and negative conductors being designated by the usual signs + and —. The positive and negative conductors of dynamo 2 lead to the switch B, and connection is made by this switch with the conductor C, which connects with the main conductor through the amperemeter D. The positive conductor from the dynamo is also connected with the main conductor by the conductor F, through the circuit breaker G.

The conductor C includes the electro-magnet, a, which controls the automatic releasing mechanism of the circuit breaker G, so that when there is a cross or short circuit upon the line, the switch G is automatically released and the dynamos are thereby protected from injury. Two switches, two circuit breakers, and two amperemeters are here shown, one of each for each dynamo. The dynamos are each provided with a resistance box, H, which is connected up in the shunt circuit of the field magnet and is used to regulate the voltage in starting the dynamo. The dynamo is started with the switch B open, and when the required voltage has been reached the switch B is closed, thereby throwing the current into the main conductors, A, A′. Should the load increase so that the action is below the normal in *either* of the dynamos, the deficiency in the series winding of the field magnet is supplied by the equalizing conductor E, thereby bringing the voltage up and preventing one dynamo from acting against the other.

At I, in Fig. 1, is represented a panel having switches by means of which the particular branch of the road connected with the panel may be thrown into or out of the circuit. Each branch of the road has such a panel in the power station. The trolley wire, T, is connected with the positive conductor at the power station, and the rails are connected with the negative conductor at the power station. At the power station the rails are connected with the main conductor by a cable, as shown.

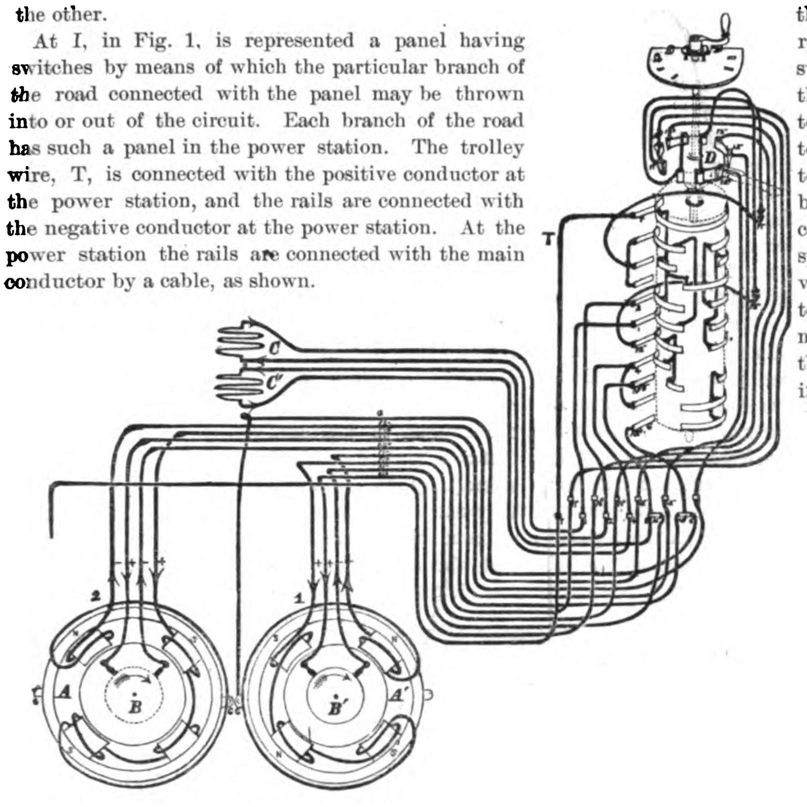

FIG. 3.—ARRANGEMENT OF REVERSING CIRCUIT.

Fig. 2 shows the details of the car wiring, motor connections, and lighting and heating circuits. To cause the car to stop or start, to go forward or backward, slow or fast, and to permit of operating it from either end, there is placed on each platform a box known as the "controller," having two hand levers at the top, one for reversing the motor, the other for varying its speed and stopping. The controller contains insulated contact springs forming the terminals of the various wires, and also a cylinder carrying a number of metallic segments for forming the various connections of the wires by contact with the different springs.

The connections, as shown in Fig. 2, are arranged for starting the car, i. e., with all the windings of the field magnet in series with the two armatures and the two resistances, C, C′. These connections can be traced by starting at the power switch, P. S. Between the power switch and the motors are located the fuse and the choke coil, cc, which latter is designed to impede a lightning discharge so as to cause the lightning to pass to the ground through the lightning arrester L A, ground connection G, motor box, car wheels and truck, rather than through the motors.

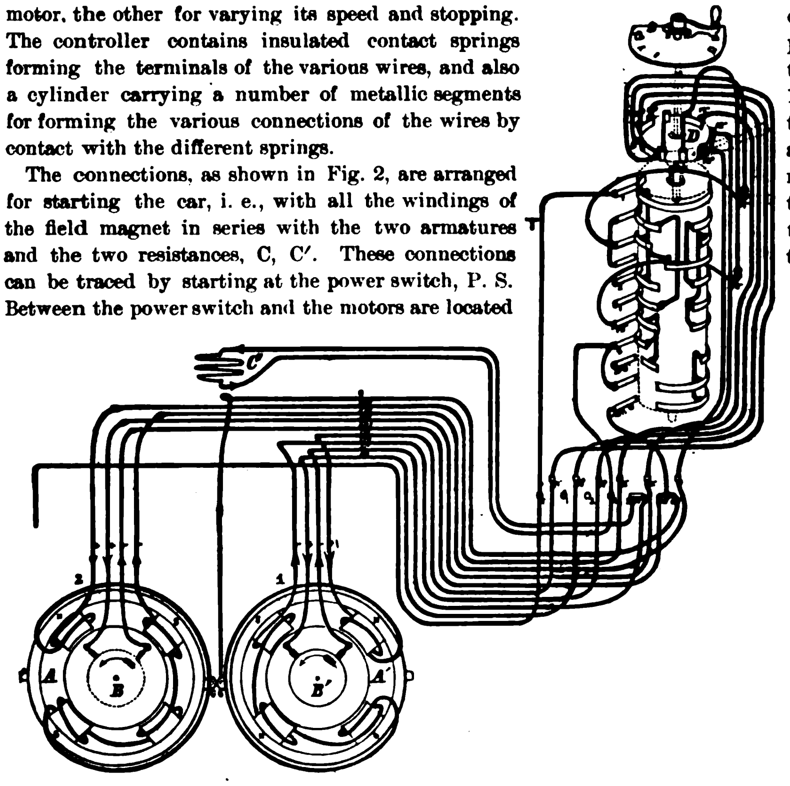

FIG. 4.—ONE-HALF OF RESISTANCE CUT OUT.

The current passes to the wire T, which is open at the rear controller, but which in the front controller touches the upper segment which communicates through wire 2 with resistance C, thence through wire 1 and the segment with one of the contacts in the reversing switch D. The current flows thence to the field magnet of the motor B′ through the wire F′—, and returns to the reversing switch through the wire F′+, thence through the wire A′+ to the armature of the motor B′, through the wire A′— to the resistance C′, thence back to the spring 4 of the controller, thence to the spring F^2—, through the reversing switch wire F^2— to the field magnet of the motor B, returning through the wire F^2+ to the reversing switch, thence to the armature of the motor B by the wire A^2—, returning by the wire A^2+ to the ground wire G, which communicates with the ground through the motor box, car truck, car wheels and rails.

Fig. 3 shows the arrangement of the controller and reversing switch when the motors are reversed. The current enters the trolley connection T as before, passing to spring 2, thence to the resistance C, spring 1, to the wire F′—, thence to the reversing switch D and wire F^2+, to the field magnet of the motor A′, thence back to the switch D, thence by the wire A′+ to the armature B′ of the motor A′, thence to the resistance C′ to the spring 4, through the segment of the controller to spring F^2—, thence by the wire F^2— to the reversing switch D, thence by the wire F^2+ to the field magnet of motor A, thence to the switch D, and back to the armature of motor B by the wire A, thence to the ground connection C.

It will thus be seen that while the current remains the same in the armatures of the motors it is reversed in the field magnets; this causes the armatures to revolve in the opposite direction.

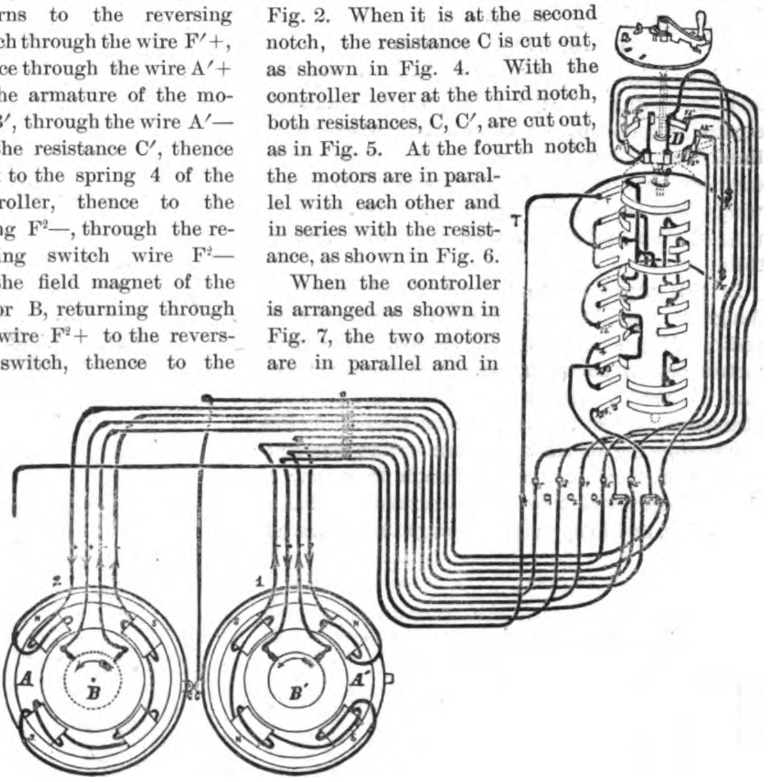

FIG. 5.—ALL RESISTANCE CUT OUT.

When the controller lever is at the first notch, the current is fully on, with both the field magnets, armatures and resistances in series, as shown in Fig. 2. When it is at the second notch, the resistance C is cut out, as shown in Fig. 4. With the controller lever at the third notch, both resistances, C, C′, are cut out, as in Fig. 5. At the fourth notch the motors are in parallel with each other and in series with the resistance, as shown in Fig. 6.

When the controller is arranged as shown in Fig. 7, the two motors are in parallel and in series with half the resistance. When the controller is arranged as in Fig. 8, both motors are in parallel, the resistances being cut out. At this position of the controller the motors assume maximum speed. In the accompanying diagrams the circuits shown in dotted lines are in parallel with like circuits shown in full lines, and these various successive changes produced in the circuit by the different combinations of connections through the movement of the controlling switch give all the graduations of power required for starting and for running at different speeds.

The generators and motors illustrated in these diagrams are of the Westinghouse type.

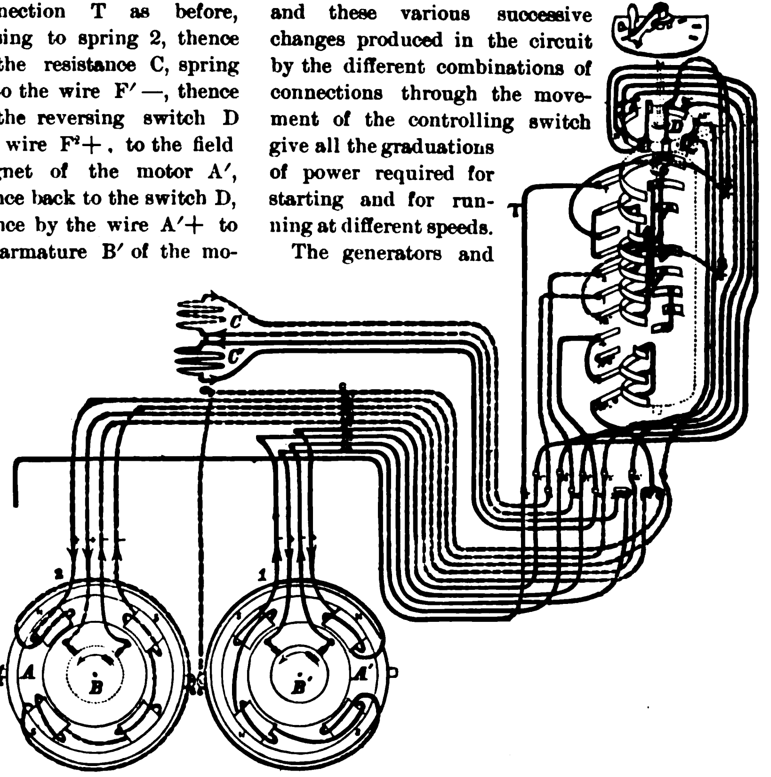

FIG. 6.—MOTORS IN PARALLEL AND IN SERIES WITH RESISTANCE.

The Railroad Commissioners of Maine have decided that the paralleling of steam lines by electric railroads is to be licensed only where a clear case of "public exigency" demands it. They hold that where such exigency exists it will be indicated by the receipts of the steam road.

The Storage Battery.[*]

A DISCUSSION OF ITS APPLICATIONS BY THE MEMBERS OF THE A. I. E. E.

THE STORAGE BATTERY FOR CENTRAL STATIONS

BY ARTHUR E. CHILDS.

It is an acknowledged fact that the great variations and fluctuations of the load on power circuits, especially those power circuits supplying trolley lines, are among the greatest difficulties which engineers have to contend against, and any appliances which will aid them to arrive at a satisfactory running of their station is looked upon with favor by them.

In this paper the term "variation" is used to designate the change of current induced by the adding of lights onto a lighting station, or the cars or motors onto a power station. The term "fluctuation" is used to indicate those rapid and necessary changes of current taking place on the outside line, due to stopping or starting of cars or throwing on or off of stationary motors. Although they may be thus differentiated, they bear a certain relation to each other, and in applying a storage battery a study of the conditions will quickly indicate the type of battery which will be more favorable in each case. By the "type" of battery is meant the slow discharge battery for a long period of service or the rapid discharge battery for a few hours or even less time of discharge.

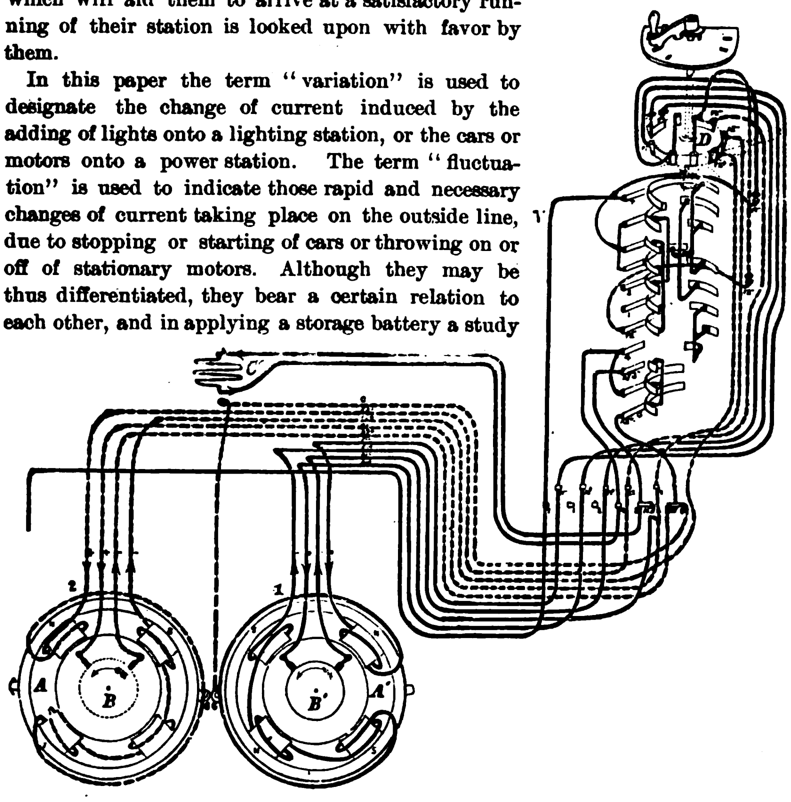

FIG. 7 (FROM BRUSH TO RAIL).—MOTORS IN PARALLEL AND IN SERIES WITH HALF THE RESISTANCE.

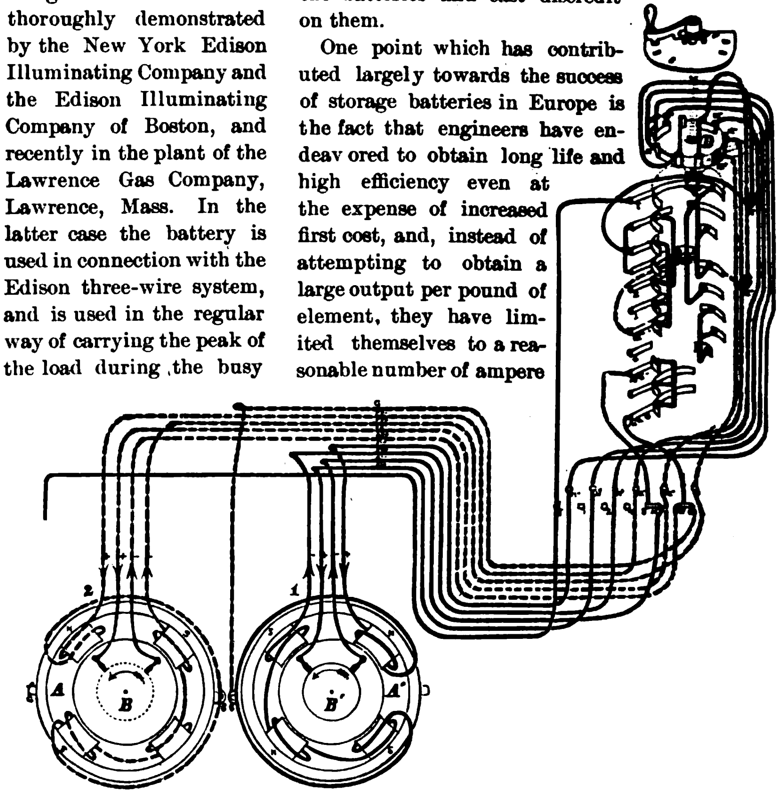

FIG. 8 (FROM BRUSH TO RAIL).—MOTORS IN PARALLEL, RESISTANCE CUT OUT.

It is not the purpose of this paper to discuss the characteristics of the electric lighting and power station curves, but to consider in a general way the application of storage batteries to the wiping out of the fluctuations and variations as they come upon the dynamos and engines. The introduction of a storage battery into a central station acts in a certain sense as a buffer between the external load and the dynamos, taking the shock of the variations without throwing the same on the engines. In this regard they have the effect of reducing the average percentage variation in load on the dynamo from a large amount to a very small one, making the operation of the machines more efficient. In fact, a storage battery acts as a regulator in this instance, maintaining as it does a constant voltage at the switchboard. As applied to power stations, and especially where water power is used, storage batteries are almost indispensable.

In the application of storage batteries to the power station of a trolley system, it is not unusual to find the variation in load as much as 50 per cent. below the average horse power, and even as great as 200 per cent. above the mean load. These enormous fluctuations take place in the course of a few minutes, and are an expense to the railroad companies in at least three ways. In the first instance, they require the use of a dynamo capacity very much in excess of that required where the station is operated at a constant load. In the second instance, these fluctuations reduce the life of the machinery of the station, producing a very large depreciation account. In the third instance, the efficiency of the generating plant is very much reduced.

When considering the application of storage batteries to illuminating plants, it is found that their value is equally as great as in the case of power stations, as the charging of the battery can be done while the plant is operating at light loads, thus making use of the power of their machines to great advantage. The value of an accumulator plant attached to an illuminating station has been thoroughly demonstrated by the New York Edison Illuminating Company and the Edison Illuminating Company of Boston, and recently in the plant of the Lawrence Gas Company, Lawrence, Mass. In the latter case the battery is used in connection with the Edison three-wire system, and is used in the regular way of carrying the peak of the load during the busy hours of lighting. A secondary use of this particular battery is that at noon, when the large mills on the Merrimac at Lawrence shut down, and entirely cut off the supply to the wheels of the gas company. During this period of absence of water the load of the lighting station is taken care of by the storage battery plant.

The storage battery can also be used as a valuable adjunct to both power and lighting stations at points in their systems where it is difficult to maintain the voltage at periods of heavy load. In these cases the feeders are usually not sufficient to carry the whole current direct from the station. But during the periods of small load the feeders can be utilized up to their maximum allowable drop in potential to charge battery sub-stations placed at these weak points. When the load at such points becomes greater than the capacity of the feeder, the battery comes into play and carries the load in connection with the station supply at that point, thus maintaining the voltage and doing satisfactory and valuable service. There must be hundreds of street railroads in this country that have just such weak points.

The extent to which storage batteries have been used in England and on the Continent is very great, and it will surprise many engineers in this country to know that there are more than 20 lighting stations and several thousand isolated plants in Great Britain alone using storage batteries. Further than this, there are in Germany 5,000 isolated plants and 15 railway power plants using storage batteries. In fact, 80 per cent. of all the central stations in Germany and Austria are equipped with storage batteries. In addition to the above, there are many stations in France, Italy, Holland, Belgium, Sweden, Norway, Denmark, Spain, and three in Switzerland.

A survey of the progress which storage batteries have made in European countries indicates no very great change in the principles of construction, but the results seem to be rather due to a thorough analysis and appreciation of the requirements of each case. This has resulted in a proper use of batteries and a correct recognition of the limitations of their usefulness. This fact alone has contributed largely to their successful application. The great difficulty in this country has been that engineers have not recognized a proper limit to the usefulness of a battery, but have, in many cases far exceeded their specified limitations, and in this way have injured the batteries and cast discredit on them.

One point which has contributed largely towards the success of storage batteries in Europe is the fact that engineers have endeavored to obtain long life and high efficiency even at the expense of increased first cost, and, instead of attempting to obtain a large output per pound of element, they have limited themselves to a reasonable number of ampere hours per pound. The result of this has been that the batteries in use in Europe have shown great endurance and solidity. The experience, however, which has been obtained with many American batteries has not been so promising as on the Continent, owing to the lack of proper appreciation of them.

The factors which tend to reduce the efficiency of a storage battery are due to a loss in voltage and in the quantity of current. These losses, however, are not so serious as they have been in the past, and manufacturers are at present able to guarantee a very high efficiency. In cells which were submitted to Prof. H. L. Callender, an ampere efficiency of 96.1 per cent. was recorded, the watt efficiency being 84 per cent. It must be borne in mind that a loss of 16 per cent. or even 20 per cent. in the efficiency of the battery does not mean the loss of the same percentage in the output of the station, as the battery usually supplies approximately, or even less, one fourth of the whole output in watt-hours, and it is, therefore, from that fraction of the whole output that the loss in the battery must be deducted.

In the matter of cost of maintenance of a storage outfit it is now usual for the manufacturer to guarantee a fixed annual percentage. This percentage varies from ten per cent. in small plants to a smaller percentage in large plants, depending, of course, on the conditions of operation and the use to be made of the battery, a study of which will soon determine what percentage can be guaranteed. In first-class plants, well installed and operated by careful engineers, the cost of maintenance can be reduced to the vicinity of 3.5 or 4 per cent. It is customary for the manufacturers to enter into a contract, in the case of large plants, guaranteeing that the cost of maintenance shall not exceed a certain percentage per annum for the period of contract. This can be carried out in two ways. Either the lighting or railroad company can pay the manufacturer the percentage specified, every year, and the manufacturer will inspect and keep the battery in first-class condition; or the company employing the batteries can inspect and order renewals themselves; in which case should the cost of maintenance exceed the percentage guaranteed, the manufacturer will not charge more than the specified amount. This is an exception rather than the rule, however, as the cost of maintenance is usually somewhat lower than that specified by the manufacturers, so that the company owning the battery is the gainer by the difference in percentage. By a thorough attention to details, both large and small, the percentage can be kept down to a very low figure.

---

[*] Abstracts of communications read at the 101st Meeting of the American Institute of Electrical Engineers, New York and Chicago, November 20, 1896.

When an entirely new power plant is to be built, there is no doubt that by adopting the storage battery in the first instance the initial cost of installation will be less than for the plant not using storage batteries, and the cost of operation of the station will certainly be very much reduced when the station uses storage batteries. In the case of existing plants which have to be extended, it has been proved that a kilowatt-hour capacity can be added more cheaply to the station by the addition of storage batteries than by the addition of generating machinery, while, of course, the cost of operation is much reduced.

Referring to the primary cost of storage batteries, the cost per kilowatt-hour output is relatively greater for small cells than for large ones, since the cost of manufacture is reduced per kilowatt-hour in the larger sizes, whereas the jars and tanks which are used to hold elements do not decrease very much with the decrease in size of the elements. The cost of shipment and erection are, of course, slightly less per kilowatt-hour with the larger sizes than with the smaller ones, and on the whole the cost per kilowatt-hour with the larger cells is less than with the smaller sizes. It is stated by the Electric Storage Battery Company that they are now installing large plants of the Tudor type at a cost per kilowatt-hour of about $37 to $40, which cost, it is understood, can be reduced in the larger stations. The question of cost, however, is one which must be studied out in each case where it is proposed to install storage batteries, and a consideration of the cost of installation of storage batteries with their attendant reduction in operating expenses, will very soon bring to the mind of purchasers that it is cheaper to invest in accumulators than to invest in additional boilers, engines and dynamos.

USE OF STORAGE BATTERIES IN ELECTRIC LIGHTING.

BY DR. FRANCIS B. CROCKER.

The function of accumulators is to receive electrical energy at one time or place and to give it out at some other time or place. The principal uses to which they may be put in electric lighting are the following: To supply portable electric lamps; to take up fluctuations and thus steady the voltage or current; to furnish energy during certain hours of the day or night and enable the machinery to be stopped; to aid the generating plant in carrying the heavier load which usually exists for only an hour or two; to make the load on the engines more uniform by charging the battery when the load is light; to transform from a higher to a lower potential by charging the battery in series and discharging it in parallel, or *vice versa;* to subdivide the voltage and enable a three or a five wire system to be operated with a single dynamo; to supply current from local centers or sub-stations.

Portable Accumulators.—The accumulator is practically the only means of supplying electric portable lamps or those which are not connected to a dynamo even if they are stationary. The primary battery is expensive and troublesome to operate, and it has never been commercially successful for electric lighting except where only a few small lamps are required.

The serious drawback with portable accumulators is their great weight. For example, a standard size which weighs 100 pounds yields ten volts and five amperes, or 50 watts for ten hours, which is just sufficient to feed one ordinary incandescent lamp of 16 candle power. This weight would be prohibitive in most cases in which the only way to carry the battery was by hand, but it might be allowable for lighting railroad trains where the weight would not be so objectionable. Their great weight would also discourage in most instances the use of accumulators for supplying lamps in places which are not connected to a generating plant, the batteries being carried back and forth from a charging station.

Accumulators for preventing fluctuations, due to unsteadiness in the driving power, are often applied successfully. A dynamo driven by a gas engine, for example, may vary periodically in speed because of the explosive action of the gas in the cylinder, and a battery connected in parallel with the dynamo will have the effect of steadying the voltage. An accumulator is generally installed in connection with a small gas engine lighting plant to enable the engine to be stopped for a considerable portion of the time and save labor and attention, in which case the battery may also act to prevent fluctuations, but its principal function is the former one. A windmill electric lighting plant absolutely requires an accumulator or some other means of storing energy, not only to eliminate fluctuations in speed, which are constantly occurring, but also to bridge over the considerable periods of calm weather.

Accumulators to enable machinery to be stopped during certain portions of the day or night. The advantage of this application depends upon the fact that in almost every electric lighting plant there are long periods during the day and late at night when the number of lamps lighted is so small that it may not pay to run the generating machinery. It must also be remembered that the total investment is increased by the cost of the battery and its accommodation because the generating plant is perfectly able to carry the load put upon the battery, since, by hypothesis, this load is a light one. Hence the machinery might be run all the time, in which case the battery would be entirely unnecessary and sufficient rest of the machinery could be secured by using different machines for the periods of light load on successive days. These statements are based upon the supposition that the battery is not used to help the dynamos at the time of maximum load, since this case will now be considered separately.

Accumulators to aid in carrying the maximum load.—If accumulators are substituted for a certain portion of the dynamo capacity the question arises whether the substitution secures any advantage. In regard to first cost, authorities differ widely. These discrepancies probably arise from the confusion between K. W. and K. W. hour of output. Most accumulators have a normal time of discharge of about 10 hours, hence the cost per K. W. hour is only one-tenth of the cost per K. W. of output, and this would, of course, vary with any change in the time of discharge. In many cases it is specious and leads to mistakes to speak of K. W. hours, to appreciate which fact we have only to realize that the K. W. hour capacity of a dynamo is almost infinite since it might run for twenty years. The actual K. W. of output, or in short, how many lamps can be simultaneously fed, is the question in electric lighting. Moreover, in most cases, the time of discharge of an accumulator is unnecessarily long, and this is particularly true when it is used to help carry the heavy load which usually lasts only one or two hours. In this case the remaining hours of available discharge are of little or no use. If it be attempted to discharge more rapidly both the capacity and efficiency are seriously reduced, and in many types the condition and very life of the battery are injuriously affected by a high rate of discharge. What is needed for the maximum load or "peak of the load diagram" is an accumulator with a normal time of discharge of two or three hours and having a correspondingly smaller first cost, bulk and weight, that is, about one-quarter of those of the ordinary forms of battery. It is evident that the time of charging need not be made as short as that of discharging, if it happened to be more convenient to charge more slowly.

The use of accumulators to enable the machinery to be stopped, usually demands a time of discharge of from 10 to 14 hours, which agrees quite well with the normal discharge rate of the ordinary forms of battery, but even then the time is unnecessarily long, since the average rate of discharge would rarely exceed one-half of the maximum rate. Consequently the battery would either be incompletely discharged or the rate would have to be made excessive at certain times.

Accumulators to maintain uniform load on the engines.—Steam engines are very inefficient at light loads. This inefficiency, in fact, is one of the chief sources of loss in an electric lighting plant. The accumulator is the most important means of accomplishing this result, although there are often methods such as gas, thermal (hot water) and steam storage, all of which have been carefully compared by Mr. Nelson W. Perry in a paper before the National Electric Light Association, February, 1895, "Storage of Energy Essential to Economy of Working Central Stations." Judicious selection of the number and sizes of the engines would enable them to be worked at a considerable fraction of their full capacity nearly all of the time, and it would seem that the same care that would be required to manage the battery might enable this to be accomplished. Nevertheless the accumulator gives more flexibility to the plant, and where introduced it often seems to considerably increase the economy of the engines by making their load more uniform and nearer their full capacity. According to the figures given by Mr. Perry in the paper cited above, an electrical horse power costs $48.68 per annum when developed steadily, and costs $117.78 per annum with a variable load similar to that of an electric light station; that is, the latter costs about 2.4 times as much as the former. This ratio seems very high but is borne out by statistics,* which give a very large coal consumption for most electric light stations. Under these circumstances almost any method of making the engine loads more uniform should increase the economy of working. Doubtless an accumulator would benefit any plant in which an engine runs for any considerable portion of the time at less than half of its full power.

Accumulators used as transformers.—If the cells of a battery are arranged in series while being charged and in parallel for discharging, a high voltage current will be required for charging and a low voltage current will be given out. The total amount of energy measured in watts is the same minus the loss of 15 or 20 per cent. which always occurs in accumulators. The result is similar to that obtained by an alternating current transformer or motor-dynamo. Such a method of transformation of potential might be employed in connection with long distance transmission of energy, the current being sent over the line at high voltage and converted to low voltage by accumulators for local distribution. For potentials of several thousand volts which are commonly employed in transmitting long distances, the number of cells required would be so great as to make this of doubtful practicability compared with the ordinary stationary or rotary transformers, but it would give uniformity in load and other advantages which may be secured by the storage of energy.

Accumulators used for subdividing voltage.—This application is similar in principle to the preceding. The most important practical case is that in which a dynamo of 220 volts charges a battery of corresponding potential, a three-wire system being supplied from the battery, the neutral wire of which is connected to the middle point of the battery. This arrangement avoids the necessity of running two dynamos and allows the battery to be placed in a substation near the districts to be supplied, so that it is only necessary to run two conductors to that point instead of three. The same principle may be applied to the five-wire system.

---

*See Report of Committee on Data to National Electric Light Association.

Accumulator sub-stations.—The plan of installing battery plants at local centers which are charged from the main station enables some of the conductors to be saved in a three or five wire system, as already stated. It also makes it possible to reduce the size of these conductors because the current which flows over them can be kept practically constant. The batteries at the various sub-stations may be connected and charged in series or in parallel. The former plan would require far less copper in the conductors, since the voltage is multiplied by the number of batteries in series and the current is the same as for a single battery. On the other hand, this high difference of potential would exist between the first and the last batteries of the series, and if one of these became grounded, any person connected to the earth and touching a wire supplied by the other battery would receive a shock due to the total voltage. This would demand that the maximum difference of potential should not exceed 500 volts, or, in other words, four batteries of 110 to 125 volts each might be charged in series and could be connected to the lamp circuits at the same time. This would practically amount to a five-wire system using accumulators to subdivide the potential as explained. If the batteries were entirely disconnected from the lamp circuits while being charged, the latter would be free from danger of the high pressure which might therefore be 1,000 or 2,000 volts if desired, the batteries being charged during the day and supplying the lamps at night. For continuous working, two batteries would be necessary. Accumulator substations not only save copper in the feeders but also reduce the cost of and loss of voltage in the distributing conductors because the batteries can be placed near the lamps to be supplied with current.

Accumulators used for two or more of the above named purposes.—As a matter of fact the employment of the accumulator for several of these purposes is the most common practice. By thus combining these different applications the plant may be rendered not only more economical but also much more flexible. For example, the battery may be utilized to help out the generating machinery at times of heavy load or when the latter is partially or wholly disabled. It often happens that it is difficult to produce or maintain sufficient steam pressure owing to poor draught or other circumstances, in which event a battery enables the boilers to be temporarily relieved of some or all of the drain upon them while the pressure is being raised to the proper point. It may also be necessary or desirable to shut down the machinery or a portion of it for a few minutes to make some repair, adjustment or change of arrangement, connection, etc.

It is also possible to feed some of the circuits from the battery while the others may be supplied at a higher or lower voltage by the machinery. In these and many other ways an accumulator may be a very convenient adjunct to an electric lighting system. The fact that it is so radically different from the machinery in its nature and action makes it very unlikely that the entire plant will be crippled at any one time, since the two sources of current are not exposed to the same dangers.

PERSONAL.

Mr. C. C. Warren, of Chicago, has been in the East for several days completing arrangements for the sale of his new alternator, described in ELECTRICITY several weeks ago. Mr. H. J. Medbery, of Mechanicsville, N.Y., has associated himself with Mr. Warren, and will have charge of the sales department.

Mr. Joseph Lockwood, of Detroit, was in the city last week.

Among the old-timers who came to New York to attend the dinner of the Magnetic Club last week were Messrs. Morris Mead and Samuel A. Duncan, of Pittsburg. Mr. Mead reports good progress in getting the wires underground in his city, and says the job will be completed in the business districts before the close of next season.

GENERAL NEWS.

What is Going On in the Electrical World.

St. Paul, Minn.—Agitation is growing here in favor of establishing a municipal lighting plant.

Fayette City, Pa.—Among other improvements proposed for this town is an electric light plant.

Fairfield, Ill.—A private company intends to ask for a franchise to erect an electric light plant here.

Trenton, N. J.—The lamp committee of the city council has decided to advise the council to advertise for bids for electric lights.

Valparaiso, Ind.—Articles of incorporation have been drawn up for a company which is to build a road from this place to Porter.

Asheville, N. C.—The West Asheville & Sulphur Springs Railway have asked the board of aldermen for a franchise to build a trolley line connecting with Biltmore.

Sing Sing, N. Y.—Warden Sage of Sing Sing prison has decided to abolish the use of kerosene lamps in the cells occupied by the convicts and substitute electric lights.

Portsmouth, Va.—M. W. Mason will apply for a franchise for an electric street railway here if the Portsmouth City Railway Company fails to carry out the provisions of its franchise in the time set.

Akron, Ohio.—The ceremony of driving a silver spike near Newburg on the 16th inst. completed the Akron, Bedford and Cleveland Electric Railroad, probably the longest trolley line in the world—40 miles.

Plattsburg, N. Y.—A preliminary survey has been made of the proposed route for the electric street railway. As soon as the trustees grant the franchise the company will prepare to start work on the line.

New Brunswick, N. J.—This city has had its first "trolley party" and the participants—100 young men and women—found so much enjoyment in the affair that it promises to lead to many other similar parties.

Santa Ana, Cal.—Steps are being taken to establish a new incandescent lighting system here. The former system became inactive about a year ago, since which time the residents and merchants had to go back to gas and oil.

Cripple Creek, Col.—The Cripple Creek Electric Company has formed for the purpose of building and operating a double track electric road to take in all the surrounding hills and reach all the mines of importance in the district.

Bristol, Pa.—The directors of the Newtown, Langhorne & Bristol Electric Railway Company have awarded a contract to G. H. S. Brabaker, of Lancaster, to build the track from Langhorne to Eden this winter. The line will be continued to Bristol in the spring.

New Albany, Ind.—The property holders of Boone township have agreed to vote a 2 per cent. tax for three years in aid of the proposed electric road between this city and Leavenworth. Other townships through which the road will pass are likely to do the same.

Chicago.—Over 15,000 joints of the new "castwelded" variety have been put in along the rails of the Chicago City Street Railway Company during the past summer and fall. Only 16 of all these thousands have been broken by the contraction due to cold weather.

Phœnix, N. Y.—A new electric light company with a capital stock of $15,000 has been formed here and will apply for incorporation. The promoters are: Robert S. Sloan, Oren F. Gaylord, Elisha B. Powell, of Oswego, and S. Dana Greene and Edward S. Taft, of Phœnix.

Bellefonte, Pa.—Arrangements are being made by the recent purchasers of Penn's Cave, in this county, to build an electric road to connect the cave grounds with the Lewisburg and Tyrone Railroad at Center Hall; also for the illumination of the cave with electricity.

San Jose, Cal.—It is considered certain that by the time the subscription list is closed, November 28, a sufficient sum will be pledged to warrant the construction of the electric railroad from San Jose to Saratoga. The board of trade is taking an active interest in the project.

Buffalo, N. Y.—The State Railroad Commissioners have decided to meet at the common council chamber in this city on the 3d of December for a hearing on the application of the new Buffalo Traction Company to establish another electric railway system in Buffalo and its suburbs.

Fredericksburg, Va.—The common council has authorized the committee on lights to contract with the Rappahannock Electric Light & Power Company for lighting the streets with arc lights for three years at $60 per light per annum. The city has been paying a higher rate heretofore.

Kansas City, Mo.—The West Side Improvement Club has passed resolutions in favor of giving the franchise for an electric street railway on Wyandotte street to the Missouri, Kansas & Texas Trust Company. The Metropolitan Street Railway Company was a rival applicant for the franchise.

Marine City, Mich.—The report that farmers have organized with shotguns to prevent the building of the electric railroad to this city is denied. The road is a sure thing, as the grading has been completed from Chesterfield to within three miles of this city, and a large gang of men are at work.

Pittsburg, Pa.—Sealed proposals will be received at the office of the city controller until 2 P. M. December 3 next, for lighting the city with electricity and gasoline for a term of four years. Blanks for bidding and further information can be obtained at the general office, Department of Public Works, Pittsburg.

Rahway, N. J.—Rumors are afloat that a number of citizens, headed by a Newark capitalist, are negotiating with the Union and Middlesex Traction Company and the Rahway Electric Light & Power Company for the purchase of the plant. The company is now in the hands of Receiver C. N. Boynton of Sewaren.

Elkhart, Ind.—The Indiana Electric Railroad Company, operating the street railroad system in Goshen and Elkhart, has executed a mortgage for $500,000 in favor of the Royal Trust Company of Chicago. The money will be used in the construction of an inter-suburban line between the two cities and for equipment.

Rochester, Minn.—At a special meeting of the city council the contract for enlargement of the electric light plant was let to the National Electric Company of Eau Claire, Wis., which, together with the J. G. Robertson Ideal Engine Company, of St. Paul, will do the construction for $3,330. The work must be completed by Jan. 1

Oswego, N. Y.—The new management of the Oswego street railway are arranging to get control of the Fulton & Oswego Falls street railway and extend the Oswego line to Fulton. The Fulton line will be converted into an electric system with power houses in both Fulton and Oswego. George N. Burt is president of the new company.

Denver, Col.—Electrician Hunt, having declared in favor of a multipolar machine for lighting the capitol, has stirred up a breeze among the manufacturers of other styles of generators, who claim that their machines are just as efficient and demand that the board shall call for bids open to the makers of all kinds of machines.

Niagara Falls.—It is now definitely settled that work on the power plant for the Canadian Niagara Company will begin within four months. It is to be pushed along with all haste so that power can be furnished within the prescribed time. The plant on the Canadian side of the river will be considerably larger than that on the American side.

Shelburne Falls, Mass.—The electric railway survey has progressed as far as the Colerain line. The committee will report to the board of trade as soon as the survey is completed and an estimate of the cost of construction obtained. It is understood that the selectmen of both Shelburne and Buckland favor allowing the cars to cross the iron bridge at the "Falls."

Windsor Locks, Conn.—The building of an electric railway from Windsor Locks to enter Rainbow or Poquonnock is again being discussed. A charter for the company was obtained from the Legislature of 1893. There is also a proposition to consolidate the Windsor Locks Water Company, the electric lighting company and the proposed tramway company into one.

Saratoga, N. Y.—The property of the Saratoga Gas and Electric Light Company has been sold by the referee, James L. Scott, on a judgment obtained in favor of the New York Security and Trust Company. The property was bid in by Lafayette B. Gleason, representing a committee of the bondholders, for $100,000. The judgment amounted to $300,000.

Boston, Mass.—The gross earnings of the West End Street Railway for the year ending September 30, 1895, were $7,746,170, compared with $6,823,879 the year before, an increase of $922,292. Operating expenses were $5,633,163, compared with $4,807,083 in 1894, an increase of $826,080. This reduced the net earnings to $2,113,007, an increase of $96,211 for the year.

St. Louis.—The authorities have decided that the Board of Public Improvements shall at once proceed to draft and send to the Municipal Assembly an ordinance providing for laying the wires in the city underground.—The St. Louis, Keokuk and Northwestern branch of the Burlington route has adopted the Hall automatic electric block signal system on its line between St. Louis and West Alton.

St. Joseph, Mo.—The plant of the St. Joseph street railways has been released from the hands of the receiver, and a new corporation, known as the St. Joseph Railway, Light, Heat and Power Company, has been organized to own and operate it. Vast improvements are to be made in the system in the spring, when the lines will be extended and the rolling stock improved; new rails will replace the old ones on many of the lines.

Bath, N. Y.—Representatives of a syndicate of railway owners have been here looking over the ground and making investigations as to the business aspects of the town in connection with the project of building an electric railway to the Soldiers' Home and to Hammondsport. They intimated that the company would begin active operations as soon as a charter was obtained.

Norwalk, O.—Clark Rude, of Sandusky, backed by substantial capitalists, will construct an electric road from Sandusky to Bellevue and Monroeville, by way of North Monroeville. The right of way has been obtained, and there is no doubt that the road will be built in the spring. This road will be extended to Norwalk and the south part of Huron county to connect with the Big Four.

***Lockport*, N. Y.**—F. H. Reed, one of the principal owners of the local trolley system, in an interview a few days ago said that a company to build an electric road to *Olcott* will certainly be organized inside of a month. He added that the enterprise will start out with ample capital, the bulk of which will be supplied by New York parties, and intimated that it may be more extensive than running to Olcott.

Sacramento, Cal.—The Central California Electric Light & Power Company (the North Yuba Canal Company) was the only bidder for the franchise for running an electric wire line along the county road between the city limits and the Placer county line near Antelope, *and the* supervisors accepted the bid. The object of the company is to complete its line from Newcastle to this city for the transmission of electricity for light and power.

Washington, D. C.—The directors of the District of Columbia Suburban Electric Railway will make an effort this fall to have Congress charter that portion of the road lying between the District of Columbia line at Rives station and the intersection of Fifteenth and H streets with the Baltimore and Washington pike. Such a charter was granted by the last Congress, but the bill did not reach the President in time to become a law before adjournment.

Great Falls, Mont.—The Boston and Montana Copper Company is contemplating extensive additions with the purpose of increasing its capacity. An expert electrician has been figuring on transmitting the equivalent of 2,500 horse power in electricity to the refinery, which would about double its present electrical power. Contracts for dynamos and other electrical machinery aggregating large sums have recently been let to an Eastern electrical manufacturing company.

Oakland, Cal.—The Southern Pacific Company proposes to change its San Pablo avenue cable line into an electric road, and is considering a system presented by the agent of an Eastern company by which the cars can be run without an overhead system. Under this plan the car takes electricity from the rail, but only one length of rail is charged at a time. As the car leaves one length of rail and goes upon another it turns levers which shut the current off the length behind and turns it upon the one in front.

Ecorse, Mich.—The township board has granted a franchise for an electric railway to Hyacinthe C. Burke, of Ecorse, and Charles W. O'Brien and Stanton Marke, of Detroit. The proposed road is named the Ecorse Central Electric Railway and the route of the main line is on Fort street, from the bridge over the Rouge, through the township to the Monguagon township line, a distance of eight miles. One of the two branch lines will run to the city limits of Wyandotte and the other to the Rouge River Improvement Company's lands. The franchise is for thirty years.

Baltimore.—The second electric locomotive for the Belt Line tunnel has arrived, and the third is expected to be finished before the end of the year. President Mayer states that by that time the electrical equipment will be completed and the entire freight and passenger service through the tunnel will then be hauled by electric motors. He adds that "in view of the successful operation of the motor in service since August 4, no doubt is entertained of the entire success of the undertaking, making railroad tunnel service, heretofore so undesirable, as agreeable to the traveling public as that in the open."

Fort Wayne, Ind.—J. J. Shippard, of Cleveland, a bondholder of the Fort Wayne Electric Railway, who was reported to have purchased the road, denies the purchase but states that there is to be a change in the capital and general course of the road. "The capital stock of the company," he says, "is to be increased to $2,000,000, or $500,000 more than the original amount subscribed. There is to be a reorganization of the company, but the present stockholders will retain their shares. The road will be known as the Fort Wayne Consolidated Electric Railway Company. The greater part of the stock will remain in the hands of the Fort Wayne people, and there will be no change in the directory, except that Mr. R. T. McDonald will be one of the new board."

Brooklyn, N. Y.—The report of the committee of the Brooklyn Bridge trustees in regard to the proposals of the Westinghouse and General Electric Companies for electric shunting or switch engines was unanimously approved by the board. In the report the committee recommended that the proposals be returned with the permission for each company to equip a train at their own expense and in accordance with the specifications already issued, and with such power and heating appliances as they shall deem advisable, under the direction of the chief engineer and superintendent, and subject to such tests as to efficiency and economy as he may direct, and if such trains shall be satisfactory a contract be entered into.

Albany, N. Y.—The aldermen have at last, after months of discussion, passed the electric light ordinance. The contract term is made five years and the maximum price for each light is fixed at 36 cents a night. The ordinance now goes to the mayor for approval.—The State Board of Regents have granted an unregistered charter to the National School of Electricity, New York.—It is understood that the Erie Canal Traction Company has entered into a contract with the Erie Construction Company to install a system for canal-boat propulsion from Buffalo to Albany at an expense of $2,250,000, and that the work will proceed as the work upon the enlargement voted for in the late election progresses. The Erie Canal Traction Company is the owner of the franchise authorized by recent legislation to be given to the Cataract General Electric Company, the rights of that company for towing purposes only having been assigned to it.

New York.—John D. Crimmins of the Metropolitan Traction Company gave a reporter last week some information in regard to the purposes of his company in connection with the street lines at present under its control and others that will eventually become a part of its extensive system. "Our canvassers are now at work along Tenth avenue," he said, "getting the consents of property owners to a change from horse to electric power. The Eighth Avenue line will probably be equipped at the same time with electric motors and the Sixth Avenue line will soon follow. How soon Lexington Avenue will be fitted by this most advanced method of street traction, the sub-trolley system, will be realized, when it is known that workmen are already engaged in Lexington avenue, at 105th street, putting in the electric plant to be used at an early date on that avenue from 105th street on. Of course, the problem of putting electric motors on the Broadway cars is an important one, but we feel that we have done and are doing the best in our power for New York so far as that great thoroughfare is concerned, and when our University place line on the west and the new Elm street system on the east side of Broadway shall have been completed and electrically equipped, the Broadway problem will be much simplified. At present there's not room for another street car in Broadway without interfering unduly with the traffic of the city."

TELEPHONE AND TELEGRAPH.

Decision Against Western Union.

A decision was rendered by the United States Supreme Court last week which holds in effect that the Union Pacific Railroad Company had no right to make a lease practically giving the Western Union a monopoly of its lines for telegraph purposes. It is held that the United States has a right to maintain a bill in equity to compel the Union Pacific to maintain its own lines of telegraph. This obligation is as strong as that which compels it to maintain its tracks. The claims of the United States for reimbursement for messages charged since 1881 are disallowed because of the impossibility of separating those which should have been free to the Government and those for which the Western Union was entitled to charge. The effect of the decision will be to annul the contracts between the two companies. It also establishes the principle that no telegraph company can, by contract with a railroad company operating one of the post roads of the United States over which interstate commerce is conducted, acquire an exclusive right to such railroads for telegraph purposes. The Union Pacific Railroad Company is required to maintain a telegraph line as well as to maintain its tracks under the law granting it Government aid.

The Law of Jurisdiction.

Chief Justice Fuller of the United States Supreme Court, in rendering the decision denying the motion to dismiss the appeal of the Bell Telephone Company from the decision of the Circuit Court of Appeals, thus disposed of the question of jurisdiction which was raised by the Bell Company:

"In this country, where there is no kingly prerogative, but where patents for land or inventions are issued by the authority of the Government and by officers appointed for that purpose, who may have been imposed upon by fraud or deceit, or may have erred in their power, or made mistakes in the instrument itself, the appropriate remedy is by proceedings by the United States against the patentee. We cannot impute to Congress the intention of narrowing the appellate jurisdiction of this court in a suit brought by the United States as a sovereign in respect of alleged miscarriages in the exercise of one of its functions as such, deeply concerning the public interests, and not falling within the reason of the limitations of the act."

Increased Facilities.

The Mason-Maxwell Telephone Manufacturing Company, Richmond, Va., makes the following announcement to the trade:

"We wish to notify you that the business of the Mason Telephone Company will hereafter be carried on by the Mason-Maxwell Telephone Manufacturing Company. All the directors of the old company are directors in the new, but we have added new blood and more capital, which greatly increases our facilities for prompt and satisfactory service. We will in the future absolutely guarantee all goods sent out by us, and our increased output will enable us to give better goods for less money than ever before.

"We trust that our dealings in the future may be as pleasant as in the past, and increase to the advantage of all concerned."

The Pacific Cable.

Joseph Chamberlain, Secretary of State for the Colonies of Great Britain, has agreed to appoint a commission to arrange the details of the construction of the proposed Pacific cable. The imperial Government, Australia, and Canada will each appoint two delegates upon the commission, which will proceed with its work as soon as possible.

A telephone circuit is to be constructed along the lines of the trolley car system in Hartford, Conn., and its suburbs, so that the conductors may communicate with the power house and the car despatcher in case of accident or delay. A telephone wire has been strung on the trolley poles, and at every eighth pole there will be a switch for making connections. Each car will carry a transmitter. The device is the invention of W. C. Fielding of Hartford.

The line work of the Orange County Telephone Company at Middletown, N. Y., is completed. When the instruments are received the exchange will be put in operation.

Edward Abner, president of the Occoquan-Woodbridge Telephone Company, has announced that his company has abandoned the idea of erecting an exchange at Alexandria, Va.

At Newcastle, Pa., the local agent of the Bell Company has been instructed to cut the price of telephones down $3 less than any rate the new Citizens' Company may make.

The Saginaw Valley Mutual Telephone Company has been granted a thirty year franchise by the common council of Flint, Mich.

H. L. Kerr, representing McGhie & Moore, of East Liverpool, O., proposes establishing a telephone exchange at Sistersville, W. Va.

The new exchange of the Northwestern Telephone Company at Oshkosh, Wis., with 300 subscribers, will be in operation within a short time.

The Home Telephone Company has been granted a franchise at Alexandria, Va., on the condition that after eight years iron poles be used.

The local Bell Company has announced that it will put in a 'phone in every business place and home in the city of Niles, Mich., the customer to have the use of the instruments free of charge.

The Commercial Cable Company intends to erect on Broad and New streets, adjoining the Stock Exchange, New York city, a million-dollar office building to be 21 stories high.

The Board of Street and Water Commissioners of Newark, N. J., has passed the franchise of the Newark Telephone Company on first reading.

The police commissioners of Albany, N. Y., have under consideration plans for a police signal system.

A telephone line is to be built between Belleville and Red Bud, Mo.

COMMERCIAL PARAGRAPHS.

"Nature smiles through Sunbeams" and "A dollar's worth of light for a dollar," the mottoes of the Sunbeam Incandescent Lamp Company, are quite as well known to the electrical reading public as the Sunbeam lamp is known to the electrical buying public. Those who have spent two dollars for one dollar's worth of light, by the purchase of poor lamps, have later come to bear witness to the fact that neither of the expressions is inappropriately applied.

The New York & Ohio Company has issued a card to lamp users which is calculated to demonstrate that "the expense does not end with the lamp itself, and is not the cost of the lamp, but the quantity and quality of light that should be given first consideration. A good lamp may be cheap at one dollar; a poor lamp may be very expensive even if it should cost nothing."

The Bishop Gutta-Percha Company, 420–426 East 25th street, New York, has issued a pamphlet devoted to a description of its products.

The second annual grand ball of the employees of the Safety Insulated Wire & Cable Company was held at Murray Hill Lyceum, New York City, on the evening of the 26th inst., under the direction of W. H. Dykeman, Thomas J. Adams, Bernard Martin, Walter E. Holloway, P. A. Galvin, Arthur Lennon, Robert E. Lee and N. J. DeLuna.

Name Plates.

The value of having the manufacturer's name and address plate affixed to the specialties he supplies has long been appreciated, and for some time past there has been difficulty in having such plates made. A well known and long established engraver and designer, whose artistic work is known everywhere, has established a department for the exclusive designing and making of these name and address plates. His name is August Becker, of 55 Oliver street, Boston, and he possesses the most complete facilities for that kind of work, his staff of designers and engravers being qualified to produce work of the highest merit. These name plates are suitable for dynamos, motors, transformers, switchboards, meters, rheostats, engines, etc., etc., etc. Mr. Becker already executes this class of work for many of the leading electrical and engine manufacturing concerns; and all others requiring anything of the kind, should not fail to communicate with him for prices, designs, etc.

A Comprehensive Catalogue.

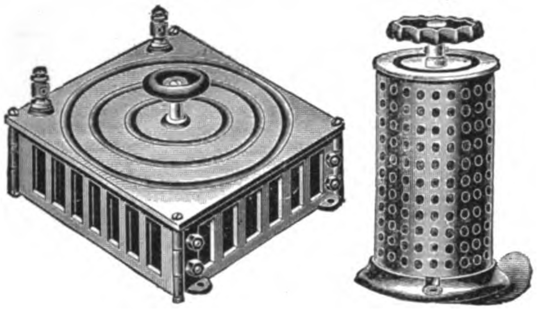
The illustrated catalogue just issued by the Metropolitan Electric Company, Chicago, is a veritable encyclopædia of everything electrical. It is composed of 760 pages, freely illustrated, handsomely printed and attractively bound. Considerable space is devoted to data, tables and other information of value to engineers, station managers and others. The book is well calculated to become a valuable addition to every purchasing agent's library.

The Graphite Rheostat.

A novel form of rheostat called the "Graphite" has recently been placed on the market by the Graphite Rheostat Company, Chicago. The accompanying cuts illustrate its appearance when finished. Although the general form of its case is similar to that of the ordinary wire rheostat, its construction bears no resemblance. The sliding arm and row of contacts are wanting in this rheostat although the hand wheel on the face is turned in the same manner.

Through the sides of the frame pass rods, and upon these rods are mounted the small slate slabs. Between the plates are iron cylinders, the whole being firmly held together by the shorter rods at the sides. These iron cylinders are filled with a specially prepared graphite. From the slate plate project rods which enter the cylinders. A rack moved by a pinion carries the cylinder over these rods. At the base of each cylinder is a brass button on the end of a bolt. When the cylinders are carried up so that the rod touches the brass button the entire resistance is cut out and there is a clear path for the current established. As the cylinders reach that point the switch in the corner is tripped and the rheostat is cut out of circuit.

Suppose it is desired to place a resistance in the circuit. By turning the hand wheel the rods leave the brass buttons at the base and at the same instant the switch is opened, throwing the rheostat in circuit; the current will then pass in series through the small sections of graphite in the cylinders. By turning the wheel farther, drawing out the rods, the sections are increased in length and the resistance in circuit increased in a proportionate amount. It will be seen from this that the amount of resistance is capable of an infinite number of variations. The number of contacts on the largest rheostat is small in comparison. This advantage will be found of value in the accurate regulation of generators, in dimmers, etc.



FIGS. 1, 2.—THE GRAPHITE RHEOSTAT.

The material used in this rheostat is not affected by heat or cold, so that there is no danger of a burn out. There being no sliding arm and contacts to wear out makes it a durable piece of apparatus. The case is of iron and of a form that gives good ventilation. The method of construction permits the making of rheostats of any resistance an easy matter. Resistance cylinders of a fixed resistance can be supplied.

This form of rheostat can be used with electro-medical apparatus and for similar purposes, in the charging of storage batteries where current of an exact amount and voltage is desired, as a motor starting box or a rheostat for the regulation of dynamos. Its construction, as will be noted, is exceedingly simple. There are no soldered connections; no wires to become brittle and break; no contacts to accumulate dirt. In Fig. 2 is shown a resistance cylinder of a different form, in which the same method of construction is employed. The case and hand wheel are nickel plated.

The Hatch Storage Battery.

The Hatch Storage Battery Company, 421 Chestnut Street, Philadelphia, is introducing a new storage battery which is claimed to be the "best and cheapest made, and which supplies all the requirements of a storage battery for all purposes." The porous diaphragm of the battery is made of unglazed earthenware. These pottery diaphragms have receptacles on their faces into which the active material is filled, while on their reverse sides they are grooved, so as to admit of a free circulation of the electrolyte of the cell. These diaphragms, loaded with active material, are then placed back to back, with the grooves crossed, and thus prepared are assembled as an element, to which the electrodes are applied. The two outer conducting sheets or electrodes are supported in position by rigid backs of glass or other suitable material, and the element thus assembled is firmly bound together with flexible rubber bands, made expressly for the purpose, thus providing an elastic element to allow for the expansion and contraction of the active material during charge and discharge.

The form of construction adopted in the Hatch Storage Battery overcomes, it is claimed, all difficulties which have heretofore beset what is commonly known as the "Grid" type of element, and in a most simple manner, while providing a battery which is cheap, light and durable, and at the same time the electrical efficiency is equal, if not superior, to the best known "Grid" batteries.

Don't Copy Their Ads.

Mr. Charles Austin Bates in the last number of *Printer's Ink* has some interesting remarks on the subject of originality in advertisements. An advertisment of the Standard Electric Company, which had appeared in certain electrical papers, was reprinted with some other good advertisements in *Printer's Ink*, and there attracted the attention of one Forrest Morgan, who immediately went into spasms, claiming that the advertisement was borrowed from one he wrote some two years ago and was spoiled in the borrowing. Mr. Bates then comments: "Mr. Morgan is exciting himself unduly. The ad. which he wrote begins, 'The latter end of the contract is vastly more important than the front end.' The ad. of the Standard Electric Company begins, 'The end of a contract, like the end of a wasp, merits respectful consideration.' Now I don't suppose that either Mr. Morgan or the writer of the other ad. is the first or only man who ever thought of that same thing. I suppose that similar expressions have been used in print and in writing and talk ten thousand times. It is nonsense for a man to claim originality in anything of this kind, or to say that somebody else is stealing his ideas. The similarity between these two ads. is not so very startling. It merely shows that two people have thought of the same thing in connection with a contract. I know that I have seen the idea used a number of times before, and the man who originated it has probably been dead some thousands of years. This continual howl and disturbance about originality is a thing well calculated to fatigue any man of experience in the advertising business. Mr. Morgan says that he thinks this ad. was borrowed and spoiled in the borrowing. As a matter of fact, if it was borrowed it was improved. There's but one end to a contract. There is a beginning and an end, and the beginning is not an end. There is no such thing as a latter end and a front end of a contract. I may be giving this subject more attention than it deserves, but this question of originality bobs up every once in a while. It is nonsense for a man to try and be original. He can't be original no matter how hard he works, and so long as he can make use of another man's ideas without hurting that other man there is no reason under the sun why he shouldn't do so." The ad. in question was not stolen, but was based on a previous advertisement reading: "Our contract does not obligate the purchaser to buy apparatus or supplies exclusively of us for a term of years," etc.

INCORPORATIONS.

The Beatrice Electric Company, Beatrice, Neb.—to operate street railway; operate electric light, heat and power plants, etc. Capital stock, $100,000. Promoters: John N. Horback, Paul W. Horback, Victor C. Lantry, John E. Smith, Albert S. Maxwell.

The Leechburg Electric Light and Power Company, Leechburg, Pa.—to supply light, heat and power by electricity to the public. Capital stock, $16,000. Promoters: J. D. Orr, Leechburg; W. W. Staub, E. F. Austin, Pittsburg, Pa.

The Quebec "Official Gazette" announces the incorporation of the Fraserville Electric Power Company. Capital stock, $25,000.

The American Audible Block Signal Company (incorporated in W. Va.), Buffalo, N. Y.—to acquire, etc., patents relating to systems of electric and other signals pertaining to railroads, etc.; selling, leasing, etc., same. Capital stock, $500 minimum, $5,000,000 maximum. Promoters: Cyrus J. Wheelock, C. W. Hammond, John T. McLaughlin, Frank S McGraw, John F. Cochrane, Buffalo, N. Y.

The Fort Wayne Consolidated Railway Company, Fort Wayne, Ind.—to operate the electric street railway system at Ft. Wayne. Capital stock, $2,000,000. Directors: John H. Bass, M S. Robinson, James M. Barrett, John J. Shepherd, Andrew Squire, Charles Gerke and Samuel L. Morris. The State's fee for the incorporation was $2,002.

The Bedford Electric Light Company, Bedford City, Va.—to manufacture electric light and supplies and furnish same. Capital stock, $25,000. Promoters: T. D. Berry, J. A. Clarke, C. E. Harris, Bedford City.

The Marysville Gas and Electric Company, Marysville, Cal.—to deal in light, power and heat. Capital stock, $500,000. Promoters: D. E. Knight, A. C. Bingham, Mary A. Knight, Thomas Syversten, Marysville.

The Albany, Helderberg and Schoharie Electric Railway Company, Albany, N. Y.—to build and operate an electric railway between Albany and Schoharie village, a distance of about thirty miles. Capital stock, $300,000. Directors: Jonas H. Brooks, John W. Van Valkenburgh, Robert J. McCauley, Albany; J. M. Erwin, New Salem; C. E. Deitz, Thomas J. Wood, Berne; Jacob Kelsch, Hiram Schoolcraft, Gallupville; E. Twitchell, C. C. Kromer, O. A. Snyder, Schoharie; Harrison Finkle, Greenbush, N. Y.

The Eclipse Electric Lamp Company, Buffalo, N. Y.—to make and sell electric lamps, etc. Capital stock, $100,000. Directors: Thomas F. Crean, Brooklyn; H. H. Fulton, Elmira; W. C. Page, New York; William Crosby, Buffalo; William Marison and Andrew Marison, Montclair, N. J.

The Chemung Gas and Electric Light Company, Elmira, N. Y.—to make and sell gas, electricity, etc. Capital stock, $200,000. Directors: C. G. S. Thomas, Arthur S Pinkham, Paul C. Safford, Frank McKelvey, John Doyle, George T. Carhart, and Albert E. Ettinger, all of New York City.

The East River and Atlantic Ocean Railroad Company, Brooklyn, N. Y.—to build and operate an electric line connecting the Nassau Electric Railway and the lines of the Brooklyn Traction Company's system. Capital stock, $3,000,000. Incorporators: P. H. Flynn, Silas B. Dutcher, J. C. Brower, F. C. Cochen, W. J. Studwell and G. S. Studwell.

The Johnson-Lundell Electric Company, New York—to manufacture and deal in dynamos and electrical apparatus to produce light in New York City. Capital stock, $500,000. Directors: Edward H. Johnson, Robert Lundell, Frank S. Hastings, Harry E. Robinson, Martin J. Quinn and Edward Beers, of New York City.

The Schenectady Illuminating Company, Schenectady, N.Y., has filed a certificate of an extension of its powers to furnish light, heat and power in the towns of Rotterdam, Glenville and Niskayuna, in Schenectady County. The capital is $100,000, and the trustees are John Kruesi, Charles A. Leb and George W. Jones.

The Skeen Electric Switch and Signal Company, St. Louis, Mo.—to manufacture electric switches, etc. Capital stock, $5,000. Promoters: A. T Gast, Chas. E. Joy, C. H. Witthofft, Ferdinand Gast, St. Louis.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 19, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

549,920. Underground Trolley System. Charlie E. Hubb Streator, Ill. Filed May 23, 1895.

550,057. Closed-Conduit Electric Railway. Herluf A. F. Petersen, Milwaukee, Wis. Filed Oct. 29, 1894.

550,059. Trolley. Francis J. Pribyl, Hazleton, Pa. Filed March 9, 1895.

550,102. Underground-Trolley System. Cornelius J. Hamilton, Philadelphia, Pa., assignor of one-half to James Lilley, same place. Filed April 26, 1895.

550,132. Electric Appliance for Railways. Herluf A. F. Petersen, Milwaukee, Wis. Filed March 19, 1894.

550,220. Electric Car or Locomotive. Rudolf Eickemeyer, Yonkers, N. Y.; Rudolf Eickemeyer, Jr., executor of said Rudolf Eickemeyer, deceased. Filed April 8, 1891.

ELECTRIC LIGHTS AND APPLIANCES.

550,215. Electric-Arc Lamp. Edouard Cannevel, Paris, France. Filed April 20, 1893. Renewed July 22, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

550,008. Self-Propelling Vehicle, Boat, etc. George A. Washburn, Cleveland, Ohio. Filed March 6, 1895

550,044. Rheostat for Use in Electric Motor Circuits. Rudolf Eickemeyer, Yonkers, N. Y.; Rudolf Eickemeyer, Jr., executor of said Rudolf Eickemeyer, deceased. Filed Jan. 14, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

550,204. Toll-Collecting Telephone Apparatus. Geo. K. Thompson, Malden, assignor to the American Bell Telephone Company, Boston, Mass. Filed Aug. 21 1895.

BATTERIES.

549,899. Plate for Storage-Batteries and Process of Making It. Francis J. Clamer, Philadelphia, Pa. Filed Dec. 20, 1893.

550,039. Galvanic Battery. Edward S. Boynton, Brooklyn, N. Y. Filed Feb. 21, 1895.

550,167. Electric Battery. Thomas Froggatt, London England. Filed May 1, 1895.

MISCELLANEOUS.

549,906. Automatic Electric Fire-Alarm. Harry A. Edgecomb, Mechanic Falls, Me. Filed Jan. 5, 1894.

549,919. Electrical Indicator. John W. Howell, Newark N. J., assignor to the Edison General Electric Company, New York, N. Y. Filed Jan. 2, 1892.

549,995. Underground Conduit. James F. Cummings, Detroit, Mich., assignor to the Cummings & Engelman Conduit Company, same place. Filed March 4, 1895.

550,018. Electrical Steering-Gear. Frank L. Dyer and Leonard H. Dyer, Washington, D. C. Filed Oct. 4, 1894.

550,042. Electric Fan. Philip Diehl, Elizabeth, N. J. Filed May 11, 1891.

550,096. Fuse-Box or Cut-Out. Augustus C. Carey, Lake Pleasant, Mass. Filed April 13, 1895.

550,192. Electric Protective Appliance. Alfred H. McCulloch, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed Jan. 24, 1895.

550,205. Electric Time-Signaling Apparatus. James T. A. Todd, Fort Worth, Tex. Filed Feb. 11, 1895.

550,210. Railway Signaling Apparatus. Benjamin Wyckoff, Asbury Park, N. J. Filed March 13, 1895.

550,229. Cycle-Alarm. Robert M. McDonald and Alexander McDonald, Dalmuir, Scotland; said Alexander McDonald assignor of one-third to Edwin Packard Brooklyn, N. Y. Filed April 6, 1895.

EDITORIAL NOTES.

Safety of Overhead Circuits.

There are a few persons interested in some branches of the electrical trades who may look upon Capt. Wm. Brophy, chief of the Boston Wire Department, as an alarmist. His declaration: "I believe the so-called insulating covering in use at the present time for high potential circuits to be worse than a delusion and snare," will doubtless provoke criticism in certain quarters. However much persons may differ with him, it cannot fairly be charged that Capt. Brophy has spoken unadvisedly, or that he has sought to needlessly alarm the public as to the dangers of overhead high potential circuits. It is simply and plainly his contention that if the practices which have obtained in the highly successful work of insulating underground circuits be applied to overhead construction, a condition approximating perfect safety can be attained.

Capt. Brophy never speaks evasively, neither does he make statements having no foundation in fact. Every well posted constructing or contracting engineer, and every central station man of experience, knows that there is not in existence a high potential overhead circuit which will maintain in all conditions of weather an insulation resistance of 20 megohms per mile per 100 volts. This is one of the requirements of the Boston Wire Department for underground circuits, and that it is not exacting or impossible to be attained is attested by Capt. Brophy, who says: "There is not an underground wire or cable used on high potential circuits in Boston the insulation of which does not exceed this."

The Safety Insulated Wire and Cable Company, which has over 100 miles of cable in Boston streets, the Habirshaw and Standard Companies, and the National Conduit Manufacturing Company, which has supplied all the conduit for the city, ought to feel gratified with Capt. Brophy's testimony to the efficiency of their work: "The almost perfect insulation of underground wires and cables has already been accomplished, and the question now to be met and answered is, can the same grade of insulation be secured for overhead circuits?"

By using so-called insulated wires on high potential circuits, distribution companies admit that such circuits are dangerous. The ordinary braided insulation used for this purpose, as every one knows, deteriorates very rapidly with age and in a very short time becomes absolutely worthless for the purpose for which it was intended. Capt. Brophy but expresses the opinions long held by many of our ablest engineers when he says: "It would be better to hang out the danger signal at once, by using bare copper wires, than to continue the use of this flimsy fraud that affords no protection to human life or property, but lures innocent people on to injury and death." The bare trolley wire has inspired a certain amount of respect which has been lacking in the case of the so-called insulated circuits.

The conditions which exist to-day are due to purchasers and the public and not to the manufacturer or engineer. The public has demanded cheap light and power. To supply it the generating company has sought to reduce the plant investment by constructing a cheap distribution system. That as high a, if not higher, degree of insulation in overhead as in underground circuits can be secured is certainly possible, but to accomplish this money must be spent for material. Wire manufacturers have long been able to produce, and anxious to sell, wires and cables of almost any insulation resistance, but most purchasers have held that anything will do for overhead lines so long as it passes for insulated wire.

Capt. Brophy's opinion as to the wisdom of burying all high potential circuits is shared by more people than it was six or eight years ago, when even central station managers protested that their companies would be bankrupted by such a requirement. To-day experience has taught them better, and the tendency is in all the larger cities to bury the wires. The captain says: "I believe that all high potential circuits should be placed underground, and I believe it can be done with ultimate profit to their owners."

This is the truth in a nutshell. The interests of the public and of the lighting and railway companies do not clash. Every lighting company which has its wires underground has found it a profitable investment, and the few railway companies which have been compelled to bury their feeder wires, after a bitter struggle against it, have become converted, and would not go back to entire overhead construction if they could. Their service is better, and operating expenses and repair account are enough less to justify the extra investment.

The question of insulation for either aerial or underground work is simply one of cost. No reasonable man will for an instant suppose that a wire which is sold for a few cents per pound above the cost of ingot copper will possess or maintain the same qualities of insulation to be found in a wire the insulating material of which alone costs four or five times as much as the copper. So long as purchasers continue to demand cheap wire, the wire manufacturers will supply it, but safe overhead circuits will never be constructed with it.

Central station men have no just cause to complain of Capt. Brophy's exacting requirements, or strictures, whichever they may choose to term them. A distribution system constructed according to his specifications will mean increased initial cost, it is true, but the economy, reliability and regularity of subsequent service will repay the outlay with interest. The wire manufacturers are quite as ready and willing to make a good, high-priced insulation as a cheap and poor one. Engineers would feel that their long-continued and well-directed efforts to secure the highest standard of excellence in all branches of the art have been not without fruit if purchasers would rise above the considerations of first cost. And finally the public, that great and exacting body which most of all needs to be considered when it is appealed to to supply a return for invested capital, would, if the distribution of electric energy were made free from all elements of danger, accord to the supplying companies a more liberal support.

One of the unfortunate features of the rapid development of the electrical industry in this country, surpassing any other new industry in the history of the world, has been the vast sums of money invested in merely tentative work. We have now had enough of this. Let us have the best.

* * *

Efficiencies of English Lamps.

Some weeks ago we published the results of an elaborate test which had been made of the leading Continental incandescent lamps, observing at the time that the results of this test showed the product of the foreign manufacturers to be vastly inferior to our own. The test of English lamps, as given in another column, certainly confirms the statement already made.

The average candle power of the sixteen 8 C. P. Continental lamps used in the first test was but 7.25. To develop that illumination an expenditure of 4.77 watts per C. P. was required. The average of eighteen 16 C. P. lamps was but 13.04 C. P., requiring an expenditure of 4.56 watts per C. P.

In the English test the 8-C. P. lamps show a slightly higher candle power but lower efficiency than the Continental, the average of the former being 7.81 C. P. and the latter 4.9 watts per C. P. In the manufacture of 16 C. P. lamps the English makers seem to have more nearly approached the American standard than do the Continental manufacturers. The average candle power of the 16 C. P. lamps used in the English test was 14.21; the efficiency 4.27 watts per candle.

Comparing the above mentioned tests with one recently made of American lamps by Prof. Thomas of the Ohio State University, the superiority of the American product in both sustained candle power and efficiency becomes apparent. This test was made under conditions closely approximating everyday central station practice, and showed that after a period of 600 hours burning the average candle power of a group of 16-C. P. lamps was 16.35, while the efficiency was 3.83 watts per C. P.

It would seem that the demand for lamps of high economy does not exist in Europe, or if it does exist the manufacturers evidently are not able to supply it. Competition has done much in America to improve the quality of lamps, but to central station managers belong much of the credit. They early saw the advantages of higher economy than was possible to be obtained from the types of lamps which were guaranteed to burn for 1,000 hours or a multiple of that number, and at an unknown watt efficiency. They persistently demanded a lamp that would develop a maximum candle power at a minimum expenditure of energy. The lamps now manufactured come up to this high standard, to which the European and Continental makers have not attained, if indeed they have attempted to do so.

MR. JAMES HOTSTUFF RHOTEHAMEL, president of the Columbia Incandescent Lamp Company, was the first purchaser of space for the grand electrical exhibit to be held in this town next spring, thereby earning this free advertisement. The last man to sign will not be so well treated.

Under the Searchlight.

Views and Opinions on Timely Topics.

"What's In It For Me?"

CHAPTER III.

In ELECTRICITY for October 16 appeared a brief sermon, under the above title, on the general subject of bribery of purchasing agents, the evils of the system, and the various moral questions involved. In that sermon it was charged that L. H. McIntyre, formerly general manager of the People's Traction Company, Philadelphia, had established corrupt relations with nearly every concern of which he bought supplies and apparatus. Among other concerns mentioned was the Peckham Truck Company, from which company McIntyre confessed having drawn a regular retainer while he was the trusted agent of the railway company, supposed to look out for its best interests in all his purchases. It was further stated that the subtle influence of the Peckham Truck Company over McIntyre was so powerful as to induce him to throw off about 125 trucks of another maker after ten months' use and substitute therefor more Peckham trucks, although repairs on the discarded trucks had been practically *nil* while repairs to the Peckham trucks had been considerable during the same period.

The main question at issue, however, was that of bribery, and not one of the merits of the trucks.

A few days later Mr. Peckham published as an advertisement a letter from Mr. Wm. H. Shelmerdine, who was a director of the People's Traction Company at the time under discussion, denying the correctness of our statements—*not as to bribery*, but as to repairs on trucks. Mr. Shelmerdine said:

> . . . The situation is exactly the reverse. That is to say, the Peckham trucks cost us comparatively nothing, while the Brill trucks proved much more expensive in maintenance.

On November 16 we published this letter in full, and reiterated our charges, making, however, no accusations against Mr. Shelmerdine, who was not in position at the time to know anything of the subject which he now discusses. In the November 16 article we addressed the following to Mr. Peckham:

> Is the charge that trucks made by your company happened, in one instance, to be improperly made more damaging to your reputation than the charges as to your relations with Mr. McIntyre? Is it less honorable for you to bear the responsibility of mistakes made by your mechanics than to rest under the charge that while L. H. McIntyre was a salaried employee of the People's Traction Co., vested with the authority of purchasing all apparatus, he, as "consulting engineer," received large sums of money from your company contemporaneously with this purchase of trucks from your company? . . .
>
> Any reasonable amount of space, say two pages, is at your disposal for a letter of this kind, and there will be no charge.

Not having heard from Mr. Peckham, we take it that he does not care to explain the relations of his company with Mr. McIntyre.

Every statement made by us in the original article was based on actual fact. Our information was official and authentic. Proof was always at hand.

In our advertising pages this week will be found some interesting letters bearing on the subject, two of which are here reproduced:

THE WILKES-BARRE & WYOMING VALLEY TRACTION CO.,
WILKES-BARRE, Pa., Nov. 16, 1895.

HENRY C. MOORE, Esq., *President Trenton Passenger Ry. Co., Trenton, N. J.*

Dear Sir: I expect shortly to have occasion to purchase some trucks and am considering the Peckham and Brill trucks. I presume you are aware of the controversy that has been going on regarding repairs of these two types of trucks which were used on the People's Passenger Railway of Philadelphia, and knowing you were president of the road at the time Mr. McIntyre exchanged these trucks for the Peckham trucks, I am anxious to learn whether Mr. Shelmerdine has stated the facts correctly in his published letter as to the relative working of the Brill vs. Peckham trucks, his statements having been disputed to me. I write to ask if you can throw any light on the matter as the affair transpired during your term of office in that company.

Thanking you in advance, I am yours very truly,

JOHN GRAHAM, Gen'l Mgr.

THE TRENTON PASSENGER RAILWAY CO. (Consolidated).
TRENTON, N. J., Nov. 21, 1895.

Mr. JOHN GRAHAM, *Pres. and Gen'l Mgr. Wilkes-Barre & Wyoming Valley R. R., Wilkes-Barre, Pa.*

My Dear Sir: I am in receipt of your favor of November 16th, stating your intention to purchase some additional trucks, and that you are undecided whether they shall be Peckham or Brill. . . .

As to the question of repairs on the Brill trucks, I did not purchase any repair parts from the Brill Company, nor were any repairs made to the trucks other than the adjustment of brakes caused by the wear of the shoes and the repair of the pilots, which was caused by the ordinary operation of the road.

As to the Peckham trucks there were several changes made in the mechanism of the trucks in order to hold up the ends of the cars.

Hoping this information will answer your purpose, I am yours very truly,

(Signed) HENRY C. MOORE, President.

Further comment is for the present unnecessary, except to refer briefly to a few remarks in the last issue of the *Street Railway Review*:

> When electrical journals stray into the street railway field they frequently make mistakes which are both amusing and harmless, so evident are the errors to everybody in the railway business. But when a journal comes out in its editorial columns and publishes statements which are not only absolutely false but bear a strong flavor of an advertisement in the guise of reading matter it should not pass without denial.

Then follows a letter from Mr. Shelmerdine which is practically the same as the one printed by us on November 16.

ELECTRICITY never strays. We occupy all fields, and hold the commanding position. But if more sense is not soon exhibited in the conduct of the *Street Railway Review* the only field that publication will occupy will be the journalistic graveyard. If the editor of that publication has an occasional lucid moment, we recommend him to study the correspondence printed above, and at the same time give us his views on the subject of bribery. Can a purchasing agent who accepts bribes give honest service to his employers?

And if Mr. Peckham has any further "reply" to make, we also urge him to take up the subject in its full breadth. Let him tell the public how much his company has paid to McIntyre and others, and whether or not he considers a business built up by the methods referred to the best kind of a business?

* * *

An Honest Critic.

A Southern Journal's View of "Electricity's" Telephone Campaign.

(From the Memphis Herald.)

> ELECTRICITY claims that this company [The Standard Telephone Company] has practised fraud in many ways and that its chief capital is the $300,000 filched from gullible "promoters." Of course there is always the possibility that ELECTRICITY may have been bought up by the Bell monopoly to fight a rival. In these days, a good deal of financiering is done in newspaper offices as reprehensible as that which is carried on in wild-cat telephone companies. It is not easy at this distance to distinguish the hired libeller from the honest journalist.
>
> In favor of ELECTRICITY it can be said that it has fought the Bell monopoly and labored for an independent telephone service. Another thing may be said for ELECTRICITY: if that paper is a hired libeller, it the most skilful and consummate counterfeiter on the globe. Every line and between the lines bear the mark of honesty and courageous sincerity.

We thank our contemporary for the expression of an honest opinion.

ELECTRICITY is laboring to promote the growth of a stable, conservative electrical industry in all branches. America has been cursed with the exact opposite of this since the formation of the Edison Electric Light Company in 1879. We want to see a solid independent telephone business. The only way to secure such an addition to the industry is to drive out the paper concerns, the frauds and shams. And nothing could go further to prolong the monopoly of the Bell Company than the continued existence of such concerns as the Standard Company, destroying the confidence of investors and inspiring a feeling of hostility in all municipalities against all independent telephone projects.

We commend to the editor of the Memphis *Herald* a careful perusal of Mr. Thurlow Weed Barnes's "defence."

Nothing in the way of outside criticism could go *so far* to convince the public that the concern has no basis on which to begin business or to ask for local franchises.

* * *

American Street Railway Financing.

A Foreign View.

The London *Electrician* for November 15, in an editorial review of Mr. E. E. Higgins's "Street Railway Investments," says:

It is decidedly interesting to learn exactly whence came all the money necessary for "power-houses," "car-barns," "welded-tracks," "radial-trucks," "vestibule-cars," and 25 H. P. "T.-H. W. P. single-reduction" motors, not to mention trolley poles and wires, feeders and copper "earth-returns." On p. 28 of Mr. Higgins's excellent compilation we have it all in plain English:

> "In facing the problem of adopting electricity as a motive power the managers of horse-railway properties, both in this and in other classes, soon learned that it was necessary to provide nearly enough money to entirely rebuild and re-equip their roads de novo. The actual selling value of their tangible assets shrank to insignificant proportions. Electric motors were too heavy for the old cars, and the latter had no selling value; the introduction of heavy electric cars made it necessary to reconstruct the road-bed and to sell the old rails at scrap prices; the old barns and car houses were usually sacrificed; and fortunate was the manager who could obtain for his horses even one-third of their original cost. Nevertheless, the old security holders had to be provided for, and naturally enough, the new investment was added to the old, and the capital liabilities were made to represent what was really the cost of building duplicate roads plus the cost of extensions. If this had been all; if new securities could have been sold at par; if the prices for apparatus and construction work had been on an entirely cash basis; and if the promoters had not generally required large profits, the percentage returns on the new capitalization, even with the duplication of investment account above described, would probably have been in nearly every case increased, particularly in the larger places. Unfortunately, however, there were many cases where these exceptionally favorable conditions did not obtain. The most common form of financing these enterprises was to issue mortgage bonds having a par value somewhat greater than the valuation placed upon the old properties, plus the estimated requirements for making extensions and equipping by electricity. Stock was then issued, frequently for about the same par value as the bonds, although the proportions varied according to the fancy of the promoters. The theory of the latter was that the sale of the bonds at a moderate discount would provide all the necessary money for the entire work, and that the net income would largely exceed the fixed charges, so that substantial dividends could be earned on the stock."

Well, we are very desirous of seeing electric traction develop in this country, but not on these terms nor anything like them. Perhaps we in England have reason to be thankful that, owing to the municipal purchase clause, financial hocus-pocus of this order is out of the question, and that owing to the small mileage of our existing tramways, the larger portion of our *in futuro* electric tramways will not be converted horse lines, but entirely new ones.

* * *

G. E. Wants All.

More Trouble at Winona.

(From the Minneapolis Journal.)

Winona, Minn., Nov. 21.—The receivership of the Winona General Electric Company is likely to terminate in a foreclosure sale. During the summer and fall, the bondholders had reached an agreement to reorganize the company, and the United States Court, which meets here next month, was to have been asked to approve this plan. Now, however, the Northwest General Electric Co. has filed claims aggregating $41,000, which they insist take precedence of the bondholders' claims. This is denied by the bondholders, and a foreclosure sale will be had to determine the priority of claims. The company went into the hands of a receiver last February, and its bonded indebtedness is $270,000.

In ELECTRICITY for July 17 and 24 there was printed a complete history of the Northwest General Electric Company's operations at Winona.

The deal comprehended a consolidation of lighting and railway interests. The thorough analysis of all official schedules of property, etc., made by us showed that the Winona General Electric Company was launched with an investment account as follows:

Winona City Railway Company	$198,808.80
New Improvements	60,000.00
Paid for Light Company	35,000.00
	$288,808.80

Upon this foundation of two worthless companies, under the consolidation, $500,000 of stock was issued and $400,000 of bonds planned to be sold in Boston. Only $270,000 of bonds were actually issued, however.

The property of the lighting company inventoried about $35,000 at first cost. Agents of the Northwest General Electric appraised it at $25,000, but the owner wanted $35,000. Mr. Byllesby said: "Ten thousand dollars is only a small matter anyway in a scheme of this kind; pay them what they want." The $35,000 was paid. Furthermore the property had actually been offered to the Northwest General Electric Company, only a few months earlier, for $25,000, as is shown by the following:

[COPY.]

WINONA ELECTRIC LIGHT COMPANY.
T. T. Hayden, J. H. Jenkins,
R. T. Doud, C. L. Bonner.

Winona, Minn., April 26, 1890.

W. G. De Celle, Esq.

Dear Sir: Mr. Hayden has just handed me your letter of the 22d, with the request that I answer it.

I do not know of anything further to say than was contained in my letter to Mr. Bonner a short time since, and the contents of which you are probably familiar.

The plant as it now stands cost us a little over $25,000, and we are willing now to sell it at that figure. Our contract with the city expires about April 1, 1891. The business as it now stands is worth $4,500 or more per annum. Referring to the terms of payment in case a trade should be made, it seems to me that as the proposition is on a cash basis, if you want anything different you are the parties to name it. Yours very truly,

J. H. JENKINS.

P. S.—The Van Depoele plant cost $17,000; the Edison plant cost $8,000.

It is somewhat difficult to see how the General Electric Company expects to get its claim in ahead of all the bonds, as $100,000 of the issue is held in trust to retire an equal amount of bonds of the original Winona City Railway Company, now held by the United Electric Securities Company and issued previous to the purchase of the property by the Northwest General Electric Company.

At any rate, a foreclosure sale will be a good way to determine the actual value of the property on which Messrs. Byllesby and Coffin planned to issue $900,000 of securities.

EFFICIENCIES OF ENGLISH INCANDESCENT LAMPS.

The London *Electrical Review* recently published the results obtained from efficiency tests of some of the leading English incandescent lamps. Of these tests our contemporary says: "The lamps were bought over the counter in the ordinary way without anything being said as to the object of the purchase. Six lamps of 8 C. P. and six of 16 C. P., all intended for use on a 100-volt circuit, were subjected to a trial at this pressure which lasted 600 hours. The necessary measurements from which the efficiency was determined were made by suitable instruments, whose accuracy was periodically checked against standards. From weekly observations the varying efficiencies were obtained, and from the figures for commencement, at the end of 350 hours, and for 600 hours, as given by a contemporary, we have plotted the curves which accompany this article. Three sets of curves are given for each size of lamp; these show respectively the watts actually taken, the actual candle-power of the lamp throughout the period of experiment, and the watts per candle-power.

"We have deduced the means for each diagram, and the curve marked 'mean' will be found to exhibit a peculiarity, in that it is in all cases very nearly a straight line. Taken the 16 C. P. lamps, the Sunbeam requires the highest power, the old Edison-Swan coming next. Below the mean fall the new Edison-Swan and the Robertson; but these change their relative positions as time goes on. Coming to candle-power, it may be noted that both old and new Edison-Swan and Robertson show higher C. PS. than the mean, the new Edison-Swan having a curious bend in the curve (1) as it first rises and then falls. The Sunbeam curve falls markedly with duration of test. Taking what is, perhaps, the most useful of the three diagrams, that of watts per C. P., we find the order of merit quite distinctly indicated, and where the Robertson lamp loses ground in virtue of its lower average C. P., it here gains owing to the small watts per C. P. It is somewhat curious that none of these latter curves intersect or cross one another.

"That 8 C. P. lamps are intrinsically different in their characteristics from those of higher C. P. is made clear by an inspection of the corresponding three diagrams for the smaller size. Not only is the relative order changed, but curves before nearly straight are here bent, and those before passing twice through one value of C. P. are now found doing so only once. The curves practically speak for themselves, and may be taken as relatively correct.

"One important fact can be deduced from these results, and it is worth while to call attention to it. The term 'lamp' is nowadays generally held to mean one of 8 C. P., and it is the custom to express central station loads in terms of the equivalent number of such lamps on their circuits. For this purpose a 'lamp' means a power of 35 watts. From the mean of the averages of the English lamps tested, it appears that 38 watts per 8 C. P. lamp is about the proper figure, so that the statistical 'lamp' is, if anything, more economical and not less so than its practical variety. On this basis 28 lamps are equal to one kilowatt, and for approximate calculations the indicated horse-power of the engines in a central station may be taken as twice the maximum total kilowatt output. The general results of the lamp tests cited show that a 16 C. P. lamp consumes power at the rate of 60 watts, and gives an average of 14.21 C. P. at an expenditure of 4.27 watts per C. P., while the 8 C. P. requires 38 watts and gives an average of 7.81 C. P. at an expenditure of 4.9 watts per C. P. These efficiencies are considerably below the figures usually given, but there are no good grounds for doubting their correctness."

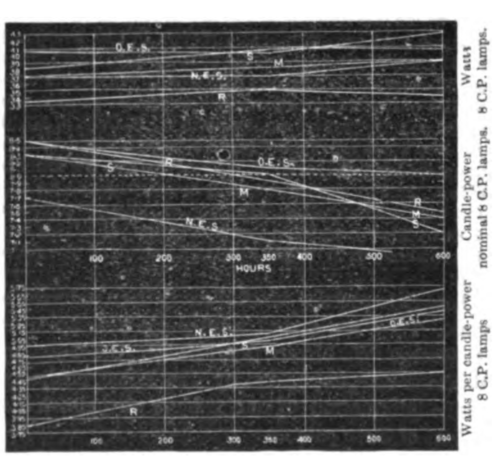

FIG. 2.

The Standard Telephone Co.

MR. BARNES'S SECOND DEFENCE.

Nothing but a Straw Foundation—String Telephones to the Front—The Patents Disclosed.

In the second "defence" made public by Mr. Thurlow Weed Barnes, president of the Standard Telephone Company, appears the following sentence:

"I am willing to be regarded as a countryman for sending any answer to your former letter."

This would be a strange confession for a man at the head of any stable enterprise to make; coming from the president of a company like the Standard Telephone Company, its humor appeals to everyone. Mr. Barnes has indeed exhibited the ingenuousness of a countryman from wayback. If his company had anything to sell, it would have been business sense to have that fact printed just as many times as possible. Having nothing to sell, it was the essence of greenness for him to expose the emptiness of his enterprise as he has done.

ELECTRICITY expresses obligations to Mr. Barnes for his remarks, and to the *Electrical Review* for bringing them out.

In his second letter Mr. Barnes has removed the veil of secrecy, and any intelligent man can now judge for himself what his company has to offer. He has given everything away, and any further attempt at secrecy or mystery is useless.

ELECTRICITY has been in possession of all the facts for many weeks, but it was deemed good judgment before presenting them to await an official avowal. Mr. Barnes has furnished this in general statements, and ELECTRICITY is able to furnish the details.

Before proceeding to analyze the foundation upon which the Standard Telephone Company built, we wish to remind Mr. Thurlow Weed Barnes that the application, in public controversy, of such terms as "clout" and "sneak" to business rivals is scarcely in accord with the code of newspaper ethics with which he was supposed to be familiar.

However, as before stated, Mr. Barnes has unwittingly exposed the "basis" on which the various companies have been incorporated with an aggregate capital of $300,000,000. It has been known all along that the parent company had no property except patents. It is for the rights under these patents that they have already taken in over $300,000 from State companies, giving to each subscriber for $1,000 in the State company $25,000 to $50,000 stock in the parent company as a bonus.

Mr. Barnes first refers to the Cole patents as follows:

> Now for the next remark, as to what patents we have under which it is thought that dividends can be earned. No doubt you have seen the sneak circulars of the irresponsible "Maxwell," who flooded the country with them, offering "$10 reward" to any one who would "furnish a complete list of the Standard patents." Suppose we now simply said patents granted originally to W. R. Cole, of Michigan. Don't you think they possess enough value to warrant agreeable anticipations? If you do not, we differ in opinion. But in any event, pray spare yourself on this point, for the Cole patents are not the only patents controlled by the Standard, a "complete list" of which was not furnished, even under the inducement of a reward of $10!

These Cole patents have already been referred to by us. They are owned jointly by the inventor, Mr. George W. Moore (counsel for the Standard Telephone Company), and by the latter company. For the information of our readers we publish the full text of these patents:

WILLIAM R. COLE, OF DETROIT, MICH., ASSIGNOR TO HIMSELF AND FRANK G. SMITH AND GEO. W. MOORE, TRUSTEES, OF SAME PLACE.

MICROPHONE-TRANSMITTER.

Specification forming part of Letters Patent No. 352,806, dated November 16, 1886.

Application filed May 27, 1886. Serial No. 203,387. (No model.)

To all whom it may concern:

Be it known that I, William R. Cole, of Detroit, in the County of Wayne and State of Michigan, have invented new and useful improvements in Microphone-Transmitters; and I do hereby declare that the following is a full, clear and exact description thereof, reference being had to the accompanying drawing, which forms a part of this specification.

This invention relates to certain new and useful improvements in the construction and operation of microphone transmitters that will be very sensitive to the human voice, while it will not be materially affected by outside influences or by jars and concussions, and at the same time be simple in construction and adjustment.

In the drawing, wherein my invention is shown in sectional elevation, A represents a wooden base having a central orifice through which the sound-waves pass to cause vibration of the diaphragm B, which is secured to a rubber ring, B, in the usual way.

C is a flexible bar, preferably of metal, with an electrode, D, secured at each end thereof.

E is a metallic contact point secured to the center of the bar and resting upon the center of the diaphragm.

F F are electrodes, one being fastened to the end of each of the adjusting screws G G, which are supported by brackets H H, which are secured to the rear face of the base A.

I I are small guide-plates to support the bar C. This bar C is placed parallel with the diaphragm, and preferably in a horizontal position.

The operation of this device is as follows: When the diaphragm is caused to vibrate, a pressure is brought to bear against the bar C (which is slightly curved toward the diaphragm) through the metallic contact-point, the vibration of the diaphragm to spring, straighten, or curve, thus bringing different pressures to bear upon the electrodes at the ends of the bar, such varying pressures being caused by the varying strength of the sound-waves and their influence upon the vibrations of the diaphragm. The electrodes F F are made adjustable by the set-screws, in order to secure the required adjustment.

Fig. 2.

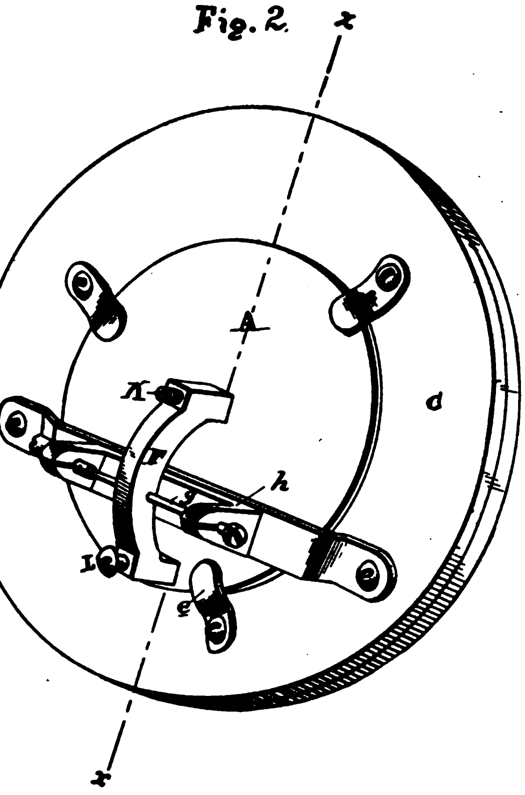

Fig. 1

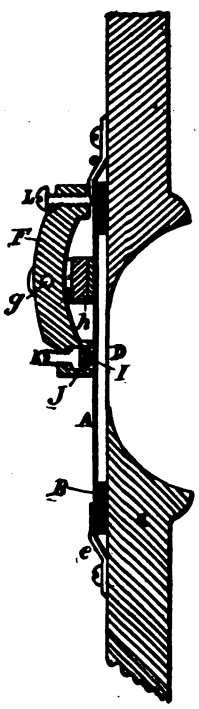


It is not absolutely necessary to have an electrode and adjusting-screw at each end of the spring-bar, as one electrode and screw at either end of the bar, with the opposite end resting against a post, will answer very well; but it is preferable to have the two, as described, as the current in passing through is varied much more. The contact point E is simply to prevent the spring-bar from resting to too great an extent upon the diaphragm. The current passes in through the bracket or post H at one end, and through the electrodes and out at the opposite end.

While the spring-bar is preferably made of metal, other suitable materials may be employed—such as whalebone, for instance—having a fine wire connected to it and connecting the electrodes D D. The guide posts or supports I I may be dispensed with, and the spring-bar may be supported by notches in the electrodes F F, in which case the ends of the bar should slightly project through the electrodes D D, to form a bearing to rest in the notches.

What I claim as my invention is—

1. In combination with a diaphragm, a horizontal curved spring-bar with an electrode at one end, such bar lying in a plane substantially parallel with the rear face of the diaphragm and with its center in contact with said diaphragm, substantially as described.

2. In combination with a diaphragm and spring-bar having an electrode at both ends thereof, one or more adjustable electrodes carried by adjusting screws and arranged in contact with the electrodes on said bar, substantially as and for the purposes specified.

3. In combination with a diaphragm, spring-bar and electrodes at each end of said bar, as described, guide posts or plates supporting such spring-bar, substantially as set forth.

4. A microphone transmitter consisting of the following elements: a base, a diaphragm, a curved spring-bar centrally in contact with such diaphragm and carrying electrodes at both ends of such bar, and one or more adjustable electrodes, the parts being constructed, supported, and arranged with relation to each other substantially as and for the purposes described.

W. R. COLE.

Witnesses:
H. S. SPRAGUE.
CHAS. THURMAN.

WILLIAM R. COLE, OF DETROIT, MICH., ASSIGNOR TO WM. R. COLE, FRANK G. SMITH, AND GEO. W. MOORE, TRUSTEES, OF SAME PLACE.

TELEPHONE.

Specification forming part of Letters Patent No. 352,735, dated November 16, 1886.

Application filed May 27, 1886. Serial No. 203,386. (No model.)

To all whom it may concern:

Be it known that I, William R. Cole, of Detroit, in the county of Wayne and State of Michigan, have invented new and useful improvements in Telephones; and I do hereby declare that the following is a full, clear, and exact description thereof, reference being had to the accompanying drawings, which form a part of this specification.

This invention relates to certain new and useful improvements in receiving telephones; and the invention consists in the peculiar construction and arrangement of the parts by means of which a very sensitive and efficient instrument is produced, more so than those now known and used. In most of the instruments for this purpose only one pole of the permanent magnet is used, and consequently with a great loss. In cases where the two poles are or have been used, they are or have been bridged or connected together with the electro-magnet, thereby causing a partial loss of the effect of the magnetism upon the diaphragm.

In the accompanying drawings, wherein my invention is shown in vertical elevation, A represents the diaphragm, which may be supported in any suitable and known manner.

B is a permanent magnet.

C is an electro-magnet or helix.

D is an adjusting-screw working within a slot, E, in the permanent magnet.

It will be observed that in my construction one pole of the electro-magnet is made fast to one pole of the permanent magnet, thus making it continuous to the other pole of the electro-magnet. This pole is placed a short distance from the free end of the permanent magnet and made adjustable, so that if the permanent magnet is too strong it can be moved farther away, so that the undulations of the current will produce the best effect upon the diaphragm.

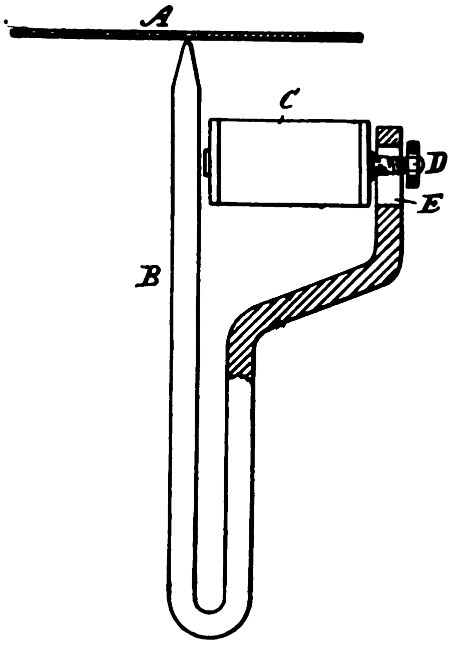
The free end of the permanent magnet B is brought almost to a point, as shown, so as to concentrate all the force thereof to the center of the diaphragm. I find by experience that this, together with the electro-magnet placed as described, has a very powerful effect upon the diaphragm, which enables me to use a stiffer diaphragm than is ordinarily employed and with a better effect.

I am aware that it has been proposed to attach an electro-magnet to one pole of a permanent magnet, and provide means for moving said electro-magnet with the arm or pole of the permanent magnet to which it is attached to or from the diaphragm, and hence do not claim such construction. I deem it important that the electro-magnet be adjustable on the pole of the permanent magnet to which it is attached, for the purposes hereinbefore set forth.

What I claim as my invention is—

1. In a receiving-telephone, a permanent magnet having one of its poles free and arranged at right angles to the diaphragm of said telephone and the other pole attached to one of the poles of an electro-magnet, arranged with its axis parallel with said diaphragm, substantially as described.

2. A receiving-telephone consisting of the combination of the following elements: a diaphragm and a permanent magnet having one of its poles free and its opposite pole adjustably secured to one of the poles of an electro-magnet, as and for the purposes specified.



3. The combination, with the diaphragm A, of the permanent magnet B, having one of its poles free and arranged at right angles to said diaphragm, and the electro-magnet C, attached to the other pole of said permanent magnet, arranged with its axis parallel with the said diaphragm and adjustable to and from the same on its pole of the permanent magnet, substantially as and for the purpose specified.

WILLIAM R. COLE, OF DETROIT, MICH., ASSIGNOR TO HIMSELF, FRANK G. SMITH AND GEORGE W. MOORE, TRUSTEES, ALL OF SAME PLACE.

TELEPHONE-TRANSMITTER.

Specification forming part of Letters Patent No. 351,250, dated October 19, 1886.

Application filed March 3, 1885. Serial No. 157,689. (No model.)

To all whom it may concern:

Be it known that I, William R. Cole, of Detroit, County of Wayne and State of Michigan, have invented a new and useful improvement in Microphone-Transmitters; and I do declare that the following is a full, clear and exact description thereof, reference being had to the accompanying drawings, which form a part of this specification.

The nature of this invention relates to certain new and useful improvements in telephone-transmitters, the object of which is to give a strong undulatory current without any break in the connection, so that the articulation may be clear and distinct, and to obviate the frying and metallic sounds produced in transmitters where the connection is not absolutely maintained.

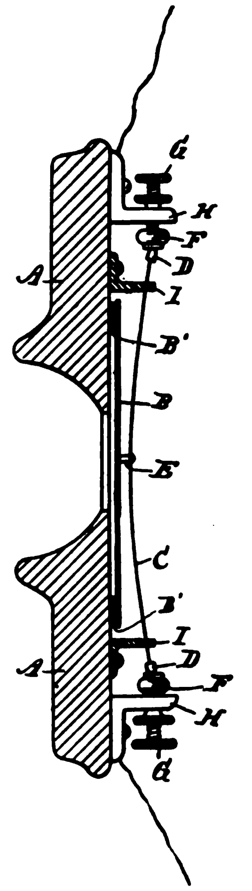
Fig. 1 is a longitudinal section on line *x x* of Fig. 2, showing the various parts. Fig. 2 is a perspective view of the same.

In the accompanying drawings, which form a part of this specification, A represents a metal diaphragm; B a rubber ring upon which the diaphragm rests.

C is a wooden base on which the rubber ring is held.

D is a mouthpiece.

e e are clamps for holding the diaphragm in its place.



F is a polarized magnet hung on trunnions *g*, which trunnions are pivoted between lugs of yoke *h*, which bridges over the diaphragm and is securely fastened to the base C, leaving a space, so that it does not interfere with the vibrations of the diaphragm.

I is a platina point secured to the center of the diaphragm.

J is a carbon button.

K is a brass or other unmagnetizable metal screw that forms a socket for holding the carbon button, and is also used for adjusting the same.

L is an adjusting screw of unmagnetizable metal, to prevent the magnet from tipping forward and engaging the diaphragm.

In operation the carbon button is adjusted to allow the magnet to attract toward the center of the diaphragm until the required amount of pressure is brought to bear upon the platinum point. The small screw L is then adjusted so as not to interfere with the vibrations, but so as to prevent the magnet from changing its position under heavy vibrations. The carbon button never leaves the platinum point, thus preventing oxidization, and the articulations are clear and distinct. The vibrations of the diaphragm upon the carbon button increase or decrease the attraction of the magnet at either end, thus varying the undulatory currents as required.

What I claim as my invention is—

1. In a telephone-transmitter, the combination, with the diaphragm, a yoke bridging the same, trunnions pivotally supported by said yoke, and a permanent magnet supported by said trunnions, of a carbon, and screws for adjusting the pressure of the carbon upon the diaphragm, substantially as described.

2. In a telphone-transmitter, the combination, with the ring C, rubber ring B, diaphragm A on said ring B, and clamps holding said ring and diaphragm to the ring C, of the yoke bridging said diaphragm and provided with lugs *h*, trunnions *g*, journaled in said lugs, magnet F, supported by said trunnions, carbon J, and adjusting-screws K L, all substantially as and for the purposes specified.

WILLIAM R. COLE.

Witnesses:
H. R. RANKIN.
M. MCNAMARA.

Discussing these patents in the order of their dates, we find that No. 351,250, of October 19, 1886, is open to criticism on the following grounds. In the first place the friction of the polarized magnet in its trunnions must of necessity militate greatly against the efficiency of the apparatus, tending to dampen down the vibrations of the diaphragm. Second, the inertia of the polarized magnet would necessarily be so great as to render it impossible for it to respond to even the vibrations of the fundamental tones, and still more impossible for it to respond to the harmonics. Third, so far as the magnetic attraction of the magnet F for the diaphragm A has any effect, it would be to tie the former to the latter so as to compel the one—a body of high inertia with one natural period of vibration—to vibrate in unison with a spring diaphragm whose inertia is negligible, having practically an infinite number of natural periods. The two are inconsistent, and the result must be that with such a transmitter the articulation would be indistinct and the reproduction of the *timbre* or quality of the tone faulty. Telephone men would, from a glance at the drawings, pronounce the instrument faulty and far inferior to other existing types. Nor is the construction such as to evade existing patents. It is clearly an infringement of the Berliner patent; but throwing that aside, it was up to the expiration of the fundamental Bell patents an infringement of those also. It could not therefore have been used up to that time, and if the Berliner patent were out of the way would not be used now, simply because it is a very inferior instrument.

Patent No. 352,735, of November 16, 1886, is for a receiving telephone. This, like the former, could not be used until the expiry of the Bell patents, because it was an infringement, and would not be used now simply because it would not work.

The principle upon which it is constructed is such as to preclude the possibility of efficient working. The assumptions of the inventor are in the first place erroneous. The polar surface on the free end of the magnet will not be at its extremity, as assumed, but directly opposite the free end of the electromagnet. There will, it is true, be a shunt magnetic circuit from the point of the permanent magnet through the air gap to the diaphragm, and thence through the long air gap to the base of the electromagnet, but the reluctance of this shunt circuit would be so enormously greater than that of the other circuit that the merest fraction of the total number of lines of force would take this path. It is these lines of force only that would affect the diaphragm, and consequently even if the variation in current were a maximum its effect on the diaphragm would be but a fraction of that produced in the ordinary Bell receiver, which is now public property.

Further, the exciting coil is on the wrong end of the magnet for best results. For effective action the polar surface next the diaphragm must be capable of responding instantly to the slightest changes of magnetizing force. For this purpose it should be of the softest iron and be surrounded by the magnetizing coil. The effect of placing the soft iron core and coil at the further end of the permanent magnet, as is done by Mr. Cole, is to render the changes at the other end sluggish and blurred and to antagonize the first principles of telephonic art. It will be seen that a worse designed receiver than this one could scarcely be conceived, since all of the magnetic laws are set at defiance.

Patent No. 352,806, of November 16, 1886, is for a microphone transmitter. It will be seen that in this the inventor endeavors to convert the to-and-fro motion of the diaphragm into motion at right angles to this by means of the toggle joint. It is evident, however, that the amplitude of the motion of the electrodes F will be but a very small fraction of that of the diaphragm vibrations. There is therefore a distinct loss instead of a gain by this arrangement. Further than this, the spring bar C, not being a diaphragm supported at all points around its periphery, will naturally respond to only one frequency of vibration, viz., its natural period—all other vibrations must be forced and will therefore tend to dampen down the waves. The patent does not mention that any of the electrodes are of carbon. Of course if they are of metal this would in itself constitute a fatal defect, but whatever the material this patent, like the two previous ones, could not have been used prior to the expiration of the Bell patents. If the Berliner patent is sustained it cannot be used now, but if the Berliner patent be declared invalid it will not be used because it is far inferior to other instruments well known to the public and open to their use.

It will also be observed that all of the patents are exceedingly limited, covering details only, and these details, as pointed out, are of no practical value whatever.

If advertised in the telephone world for one month and sold at public auction, the Cole patents would not bring $5 a piece.

We quote again from Mr. Barnes:

> Finally, will I name the sub-companies controlled by the Standard? Why should I, simply because you ask that I should do so? I fail to see by what right you, or any other editor, put forth questions of this sort, and failing to get what is regarded by you as a satisfactory reply, straightway seek to assume that you have not been treated with due consideration. Suppose I should answer: The Standard controls the "*McDonough*" and the "*National.*" That would not necessarily tell the whole story.

Indeed this would not tell the whole story. In our issue for November 27, ELECTRICITY stated the facts as regards the McDonough Company and the McDonough patents:

> The Standard Company does not own the McDonough patents. It owns the controlling interest in the McDonough Company. The McDonough Company does not own the McDonough patents. It has a license under those patents for five States only. The Strowger Company of Chicago owns several State licenses also, and has already sold the territory of Philadelphia and New York City. It will cost any company more in litigation to decide who does own the McDonough rights in various localities than the patents are worth. Mr. Barnes knows this. So does Mr. J. Wesley Allison.

Well posted telephone men must have smiled when they read Mr. Barnes's official claim to ownership in the National Telephone Company of New Jersey.

Mr. R. L. Lawrence, Esq., receiver of the Consolidated Telephone Company, sold the patent assets of this company to various individuals who afterwards organized the National Company. The patents owned by the latter company are illustrated below, with brief descriptions giving the inventors' claims. Copies of all the patents have been in our possession for several weeks. Nothing could go further to prove Mr. Barnes a countryman than his mention of these patents.

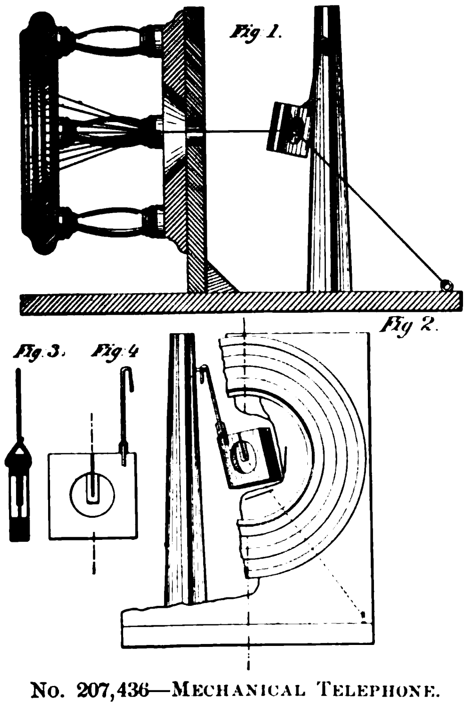
PATENTS OF THE NATIONAL TELEPHONE COMPANY OF NEW JERSEY.

No. 207,436—SCHUYLER S. PARSONS, FRANCIS R. SHAW, AND GEORGE N. DANIELS, OF CHATHAM CENTER, O.

Improvement in Mechanical-Telephones.

Dated August 27, 1878.

This invention relates to improvements in acoustic telephones, so that in place of the usual muffled tone a clear sounding of the diaphragm is obtained, and the confused ringing tone in common telephones done away with; and the invention consists of a diaphragm of cloth or other textile fabric that is mounted in an open wooden case. The transmitting-wire branches out into a number of smaller wires that are jointed to the main wire and attached to the diaphragm. The main wire is hung to insulators, which are made of sheepskin that is placed in a frame with a central opening, the frame and sheepskin being slitted, and the latter re-enforced at the slit.



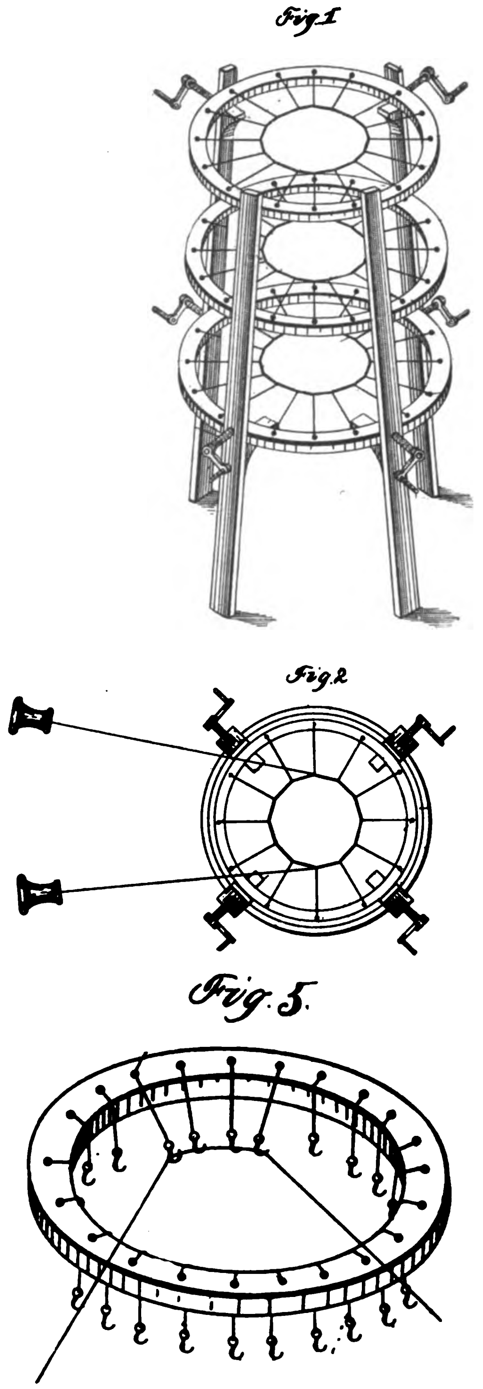
No. 207,436—MECHANICAL TELEPHONE.

No. 266,056—GEORGE F. SHAVER, OF ERIE, PA.

Mechanical-Telephone Exchange.

Dated October 17, 1882.

So far as I am aware, a system of mechanical telephone lines with a central station has heretofore not been established, and for this reason the use of such telephones has been very limited. It is well known that mechanical telephones are very efficient as sound-conveyers; but as their use has been limited to a single wire or line they have not gone into as general use as they would have done had they been considered as capable of operation in a general system with a central station as are electric telephones. The means which are essential in order to establish a system of mechanical telephone wires with a central station are naturally as follows: means for hanging the wire so as to turn abrupt angles without affecting the conduction of sound, so that all the lines can be carried to a common point or station, and so that any one of these converging lines may be connected with any other one in such a manner as to make the communication perfect from any one line to another; also, means whereby three or more of the lines can be connected together, so that a person at the end of one line can communicate with persons at the ends of two or more lines at the same time. A system of wires having these means would be adequate for all general requirements. Much of the success of such a system must depend upon the line-hanger or angle-hanger, for without this being efficient the central station could not be approached and entered by but few lines in cities or large towns; but the device by which various of the converging lines can be connected (which device, in electrical telegraph or telephone parlance, is known as the "switchboard," and therefore may with propriety be so named here) constitutes the really essential features of a central station.



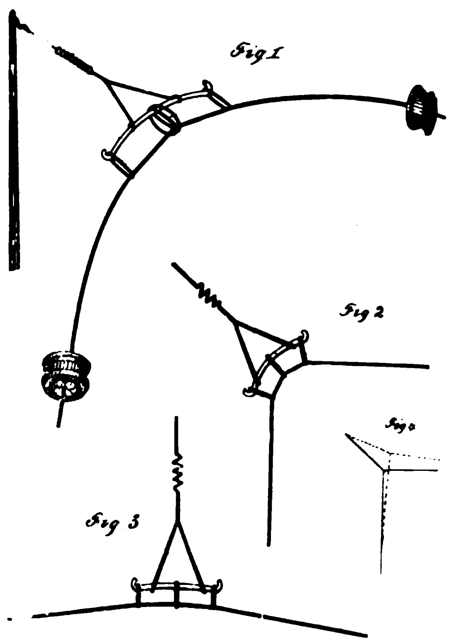
No. 266,056—MECHANICAL-TELEPHONE EXCHANGE.

No. 278 750—GEORGE F. SHAVER, OF ERIE, PA.

Angle-Hanger for Mechadical-Telephone Lines.

Dated June 5, 1883.

This invention relates to devices for suspending the wires of mechanical telephones, and it consists in providing a new and improved angle-fastener.



No. 278,750—ANGLE HANGER FOR MECHANICAL-TELEPHONE LINES.

In suspending the wires of mechanical telephones it is necessary that they be so adjusted that they will remain taut during the various changes in the temperature. This is a difficult thing to do, especially when the line has to change its direction. It is not difficult to draw a straight line taut and keep it so, but when the line has to pass around corners of streets and make various other angles and curves it becomes very difficult to put it up taut and keep it so.

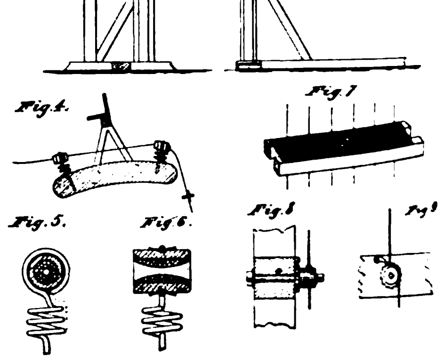
The object of this invention is to provide an angle-fastening which will overcome fully, or as nearly so as possible the abovenamed obstacles and defects.

No. 328,243—GEORGE W. MOORE, OF NORTH EAST, PA., AND JOHN N. CULBERTSON, OF BUFFALO, ASSIGNORS TO THE CONSOLIDATED TELEPHONE COMPANY, OF NEW JERSEY.

Acoustic-Telephone Exchange.

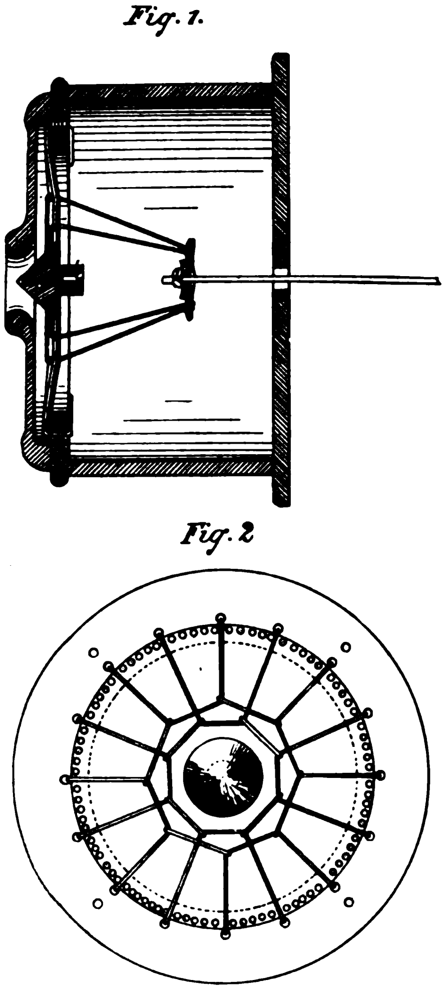
Dated October 13, 1885.

This invention relates to certain improvements in acoustic telephone exchanges in which a number of sound-tra



No. 328,243—ACOUSTIC TELEPHONE EXCHANGE

mitting wires converge, and in which means are provided whereby any two of said wires can be connected together



No. 342,395—Mechanical Telephone.

so as to transmit the sound from the telephone at one end of the wire through the exchange to the telephone at the end of another wire.

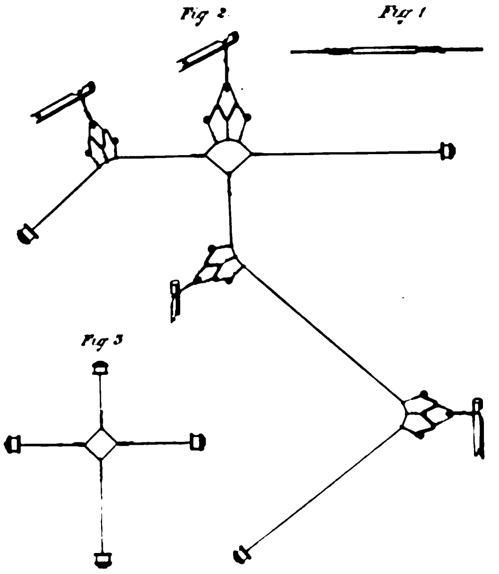
The object of our invention is to provide ready means for establishing communication between the exchange or central office in which the wires converge and the telephones at the end of such wires, and also to provide ready means for connecting any two of the converging wires.

No. 342,395—GEORGE F. SHAVER, OF NEW YORK, N. Y.

Mechanical Telephone.

Dated May 25, 1886.

The invention relates to improvements in mechanical or acoustic telephones; and it consists, first, of the attachmen of the line-wire to the diaphragm by means of supplemental wires arranged in a double truncated cone, or two truncated cones; second, in the use of a weight or weights fas-



No. 352,577—Line Connection for Mechanical Telephones.

tened to the diaphragm to lessen its vibration, and, third, of a sound-deflecting device attached to the receiving side of the telephone.

No. 352,577—GEORGE F. SHAVER, OF NEW YORK, N. Y.

Line-Connection for Mechanical Telephones.

Dated November 16, 1886.

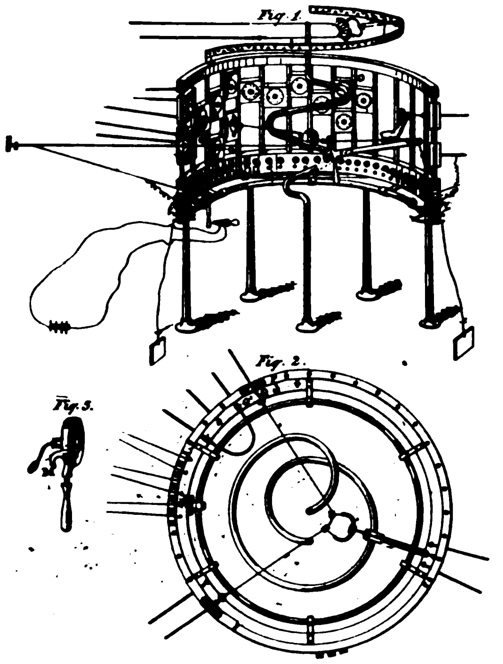
The object of my invention is to provide means whereby one or more branch wires in mechanical telephones may be connected with the main wire, and all the wires may be kept at the same or substantially the same tension, so that the vibrations conveyed to distant telephones will be of substantially the same strength.

No. 354,942—GEORGE F. SHAVER, OF NEW YORK, N. Y.

Mechanical-Telephone Exchange.

Dated December 28, 1886.

The invention relates to improvements in mechanical-telephone exchanges from which radiate a number of wires for telephonic communication, and wherein any two wires



No. 351,912—Mechanical-Telephone Exchange.

may be connected, so that communication may be made from the farther end of any one of said radiating wires to the farther end of any other.

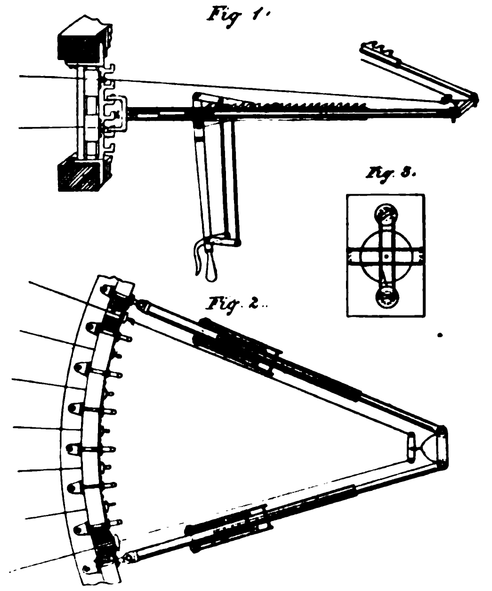
The object of my invention is, first, to provide an easy means of making such connections; second, means for keeping the wires taut when connected; third, providing means whereby many pairs of wires may be connected at the same time without interference; fourth, providing means whereby the operator may easily connect his telephone with any line-wire and tighten the wire. I attain these objects with the mechanism illustrated in the accompanying drawings hereinbefore mentioned, in which similar letters refer to similar parts throughout the several views.

No. 365,868—GEORGE F. SHAVER, OF NEW YORK, N. Y., ASSIGNOR TO BENJAMIN P. WHEELER, OF SAME PLACE.

Mechanical-Telephone Switch.

Dated July 5, 1887.

In mechanical telephones when a person in one place desires to communicate with some one at a distance it is necessary to make a connection between the wires leading



No. 365,868—Mechanical-Telephone Switch.

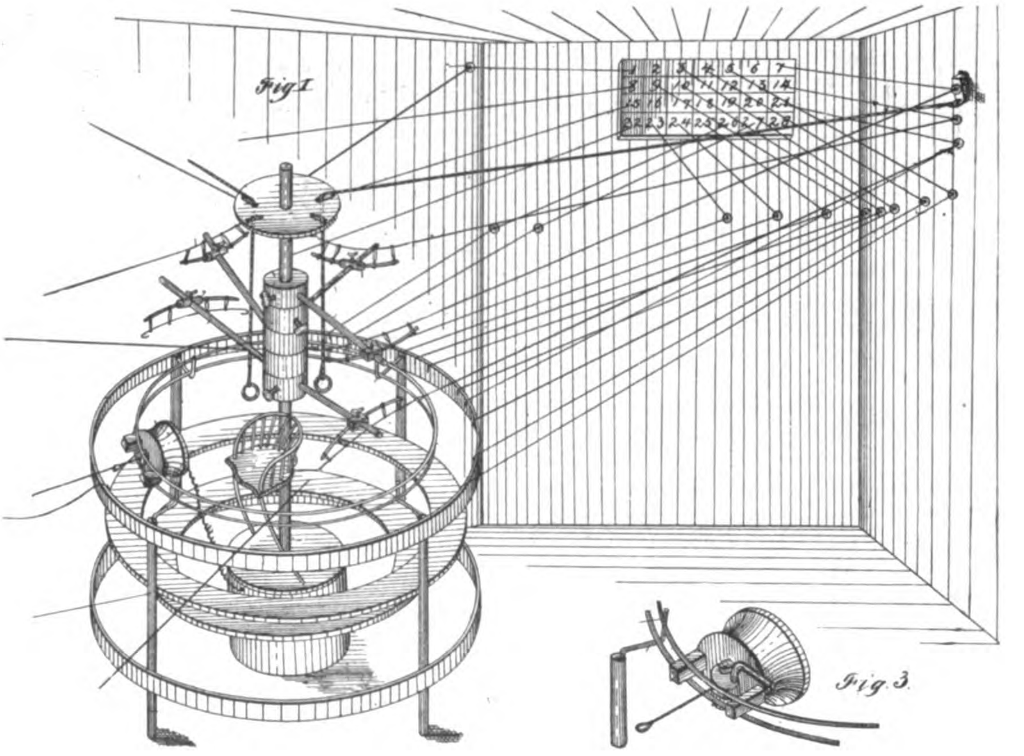
to the two places which shall make them act as one continuous wire. For this purpose the various wires of a telephone system are all led into a central or switching office, where their terminals are arranged and supported in a convenient position for connecting any two of them at will, giving them the proper tension for use.

No. 298,243—GEORGE F. SHAVER, OF ERIE, PA., ASSIGNOR TO THE CONSOLIDATED TELEPHONE COMPANY, OF NEW JERSEY.

Mechanical-Telephone Exchange.

Dated May 6, 1884.

This invention relates to mechanical telephone exchanges; and it consists in providing certain new and useful improvements in the apparatus necessary for establishing communication, when desired, between the various converging lines; also, in providing improved means for signaling to and from the central office or exchange and the several patrons; also, in several minor details relating to the ad



No. 298,243—Mechanical-Telephone Exchange.

justment of the wires, etc., which will be fully explained hereinafter.

The history of string telephones is enshrouded in the mists of antiquity, and ELECTRICITY confesses that it cannot give the date of their first introduction. Egyptologists have found relics of systems as good as Mr. Shaver's in the tombs of the Pharaohs. But we know of no researches which have discovered a telephone exchange equipped with this system.

It has been established beyond a peradventure that mechanical or string telephones were in use in Spain over 500 years ago. There is nothing electrical about the device. Mr. Shaver's patents cover simply a ridiculous elaboration of the lovers' telegraph system—or two tin cans connected by a string, with which every schoolboy is familiar.

Mr. Barnes has added little to his own reputation, or that of his company, by declaring the patent assets of the National Telephone Company to be part of the assets of the Standard Telephone Company. But in his two letters he has contributed something of permanent value to the comic literature of telephony.

Regardless of the influential men connected with the enterprise, the Standard Telephone Company is proved to be, on Mr. Barnes's own statement, a ridiculous windbag. The misguided gentlemen who have gone into State companies, and contributed their thousand dollars apiece, have been grossly swindled. The Standard Telephone Company has never had anything whatever in the way of patents or patent rights of any value. The company has never possessed the possibilities of a successful telephone business. Yet we do not see from our limited knowledge of law how any of the men who have paid their thousand dollars apiece can recover anything from the Standard Telephone Company or Mr. Thurlow Weed Barnes. Receipts for the money paid have all been signed by Allen T. Nye personally, and these receipts were evidently made up under the best legal advice. All the money received has been deposited in the name of Allen T. Nye personally, and there is little doubt, considering legal responsibility independently of moral ethics, that Mr. Nye was entitled to the money.

ELECTRICITY will have few additional comments to make on the affairs of the Standard Telephone Company. It has been proven to be by its own official statements all that we charge. It has had from the beginning no basis for business, and we doubt if the parent officers have had any intentions of doing a telephone business. As the company has truly said in its first prospectus, "The first essential for a great telephone business is an instrument of the first rank." No such instrument has been disclosed to the public, and we will only add that the Standard Telephone Company has now been in the field for nearly one year. If they had begun to do any legitimate business, one of their first purchases would be that of telephone cables and wires. We are prepared to state that the aggregate purchases in this line of the Standard Telephone Company have not amounted up to date to one thousand dollars' worth.

Mr. Thurlow Weed Barnes has confessed himself a countryman, and this statement cannot be questioned. The best thing that he could do now is to retire from all connection with the Standard Telephone Company, and to leave to Mr. Allen T. Nye the burden of all explanations as to the affairs of that company from its beginning to its end—and the latter is not far off.

Address Wanted.

A correspondent of ELECTRICITY desires to learn the present address of Mr. Frederick H. Angel, formerly an insulated wire salesman.

Dangerous Dynamos in Jersey.

(From the Jersey City News.)

One of the large dynamos in the Jersey City Electric Light Company's Works, at Wayne and Fremont streets, exploded last evening a few minutes before 7 o'clock.

THE NEW YORK INDUSTRIAL BUILDING.

Where the Grand Electric Light and Railway Exhibit of 1896 Will be Held.

DETAILS OF CONSTRUCTION AND ARRANGEMENT.

Intense interest has already been aroused in regard to the great electrical exhibit to be held in this city next spring under the auspices of the National Electric Light Association.

The National Electrical Exposition Company, having direct control, has been incorporated for the purpose.

The officers of this company are Harrison J. Smith, (Superintendent of the Edison Illuminating Company of New York), President ; Wm. F. Weiss, (Vice-president of the New York Steam Company), Vice-president ; George F. Porter, Secretary and Treasurer.

The executive committee, which is the governing power of the company, is composed of H. J. Smith, C. O. Baker, Jr., R. B. Corey, H. L. Lufkin, E. F. Peck.

The board of Directors consists of H. J. Smith, C. O. Baker, Jr., John A. Seely, R. B. Corey, W. A. Stadelman, H. H. Harrison, H. L. Lufkin, W. F. Weiss, J. W. Godfrey and E. F. Heck.

It is believed by all familiar with the enterprise that the exhibit will surpass in interest any heretofore held, not excepting that at the World's Fair That the entire trade may be made acquainted with the extraordinary opportunities offered for a grand display, ELECTRICITY has been at pains to secure full information regarding the facilities in the building where the exposition is to be held.

To provide a permanent structure, completely appointed, as a suitable place for holding trade expositions of all kinds, was the primary object of the projectors of the New York Industrial Building, otherwise known as the Grand Central Palace. For this purpose an immense area of floor space, all perfectly lighted both day and night, is an essential. Such a building, to best serve its purpose, must be centrally located. The structure must be substantial in construction and proof against dangers by fire. That all these requirements are met by the New York Industrial Building is admitted, and that it has fulfilled all the expectations of its projectors is attested by the large number of trade displays which have been made within its walls. The furniture trades have contracted for space for the tenth exhibition to be held next January. Four flower shows, four food shows, and numerous other expositions have

NEW YORK INDUSTRIAL BUILDING—A CORNER OF AUDITORIUM.

from time to time been held here. The International Permanent Exhibition Company for some time past has maintained a permanent industrial and commercial exhibit which has been largely instrumental in creating for the exhibitors a profitable and increasing trade with Spanish-American and other foreign countries.

The American Manufacturers' Exhibits consist of samples of goods, machinery and agricultural implements suitable for export, to which the manufacturers of the United States desire to attract the attention of foreign buyers.

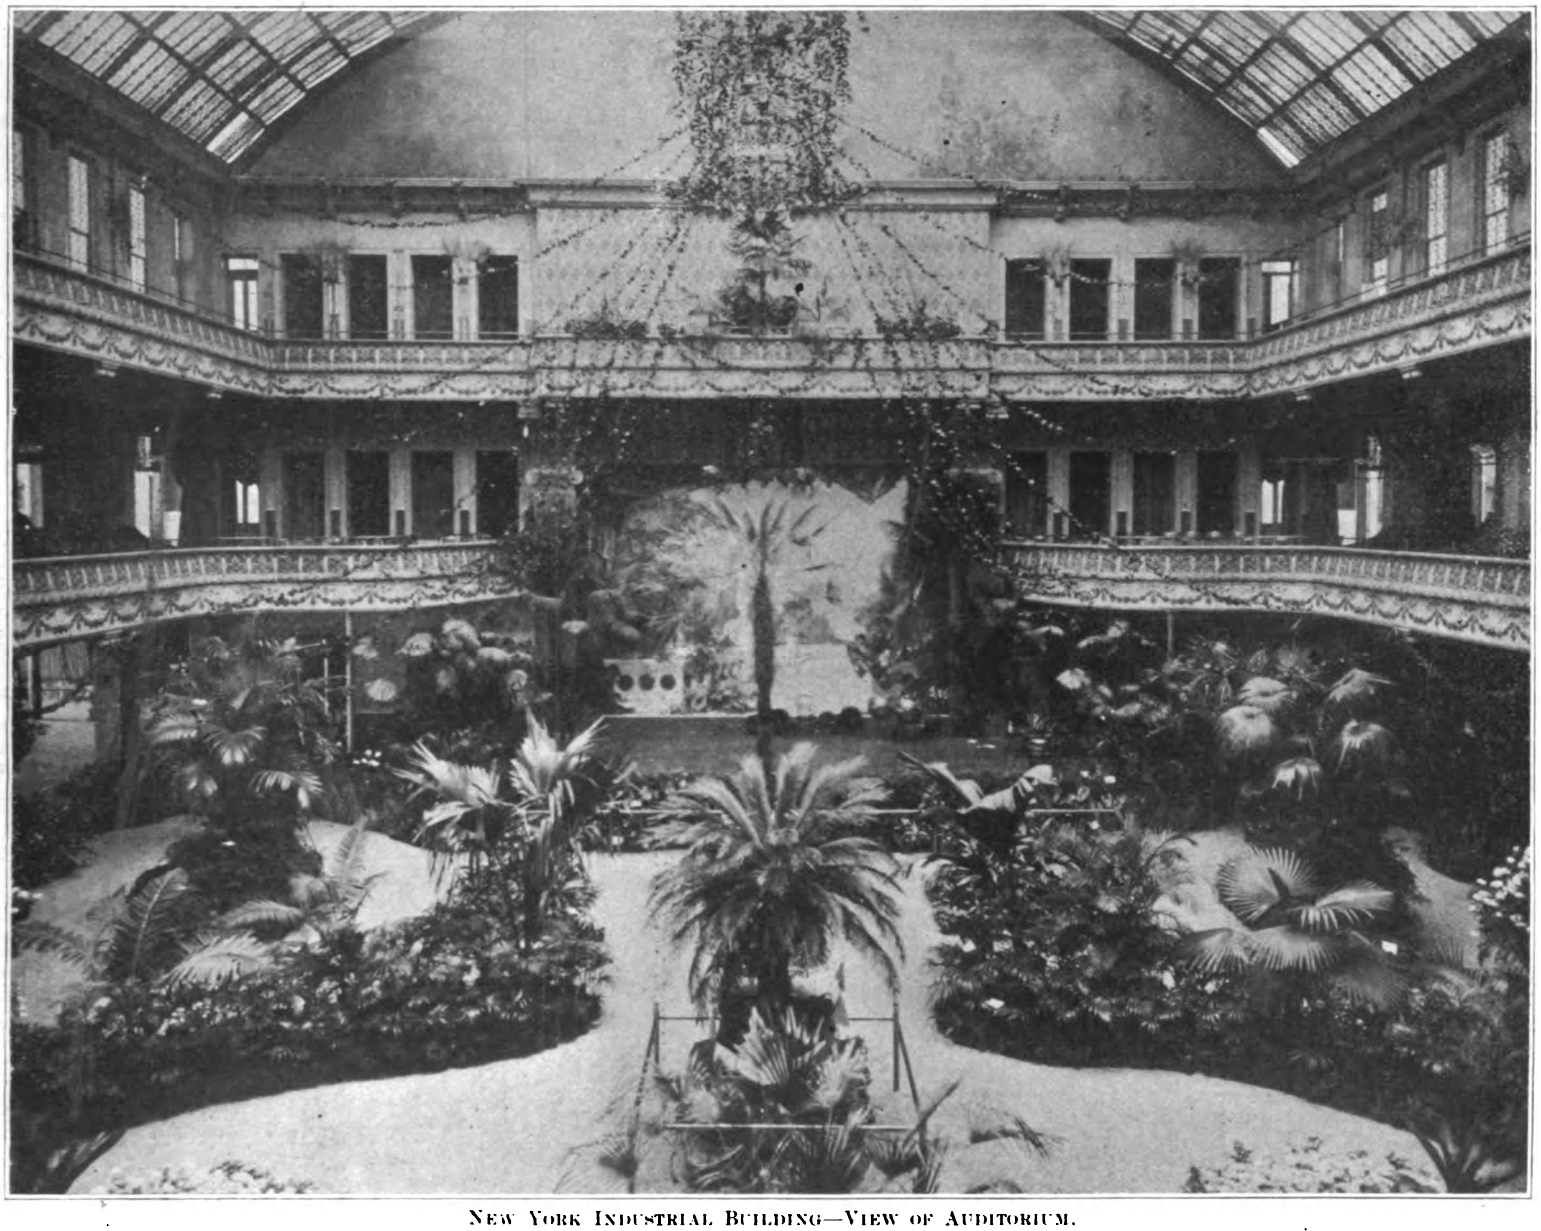
Among the great American industries there is none that shows a more marked advancement than railway appliances.

That all these improvements may be more fully brought to the attention of the buyers of the world, a special department for the display of railway appliances, both steam and electric, has been established. For this purpose, a space on the ground floor of this building on the 43d street side, 56 feet wide by 200 feet long, has been set aside to be so arranged with tracks and electric power that street cars may be fitted up and shown as in actual use, and any appliance requiring power may be operated, thus enabling prospective buyers to make practical tests of the merits of same. Not only are foreign buyers attracted, but the trade at home have a convenient place where they can inspect all important inventions.

While the International Permanent Exhibition Company is not organized to do a commission business, it will act as agent for its patrons for the introduction of their goods in foreign markets.

Detailed information will be furnished manufacturers, upon inquiry, concerning commercial opportunities and the demand for specified products in any locality, together with reports upon prices, duties, etc.

Adjoining the Grand Central Station of the New York Central & Hudson River Railroad, the Industrial Building is easily accessible from all parts of the city. The entire block bounded by Lexington avenue, Depew Place and 43d and 44th streets is occupied by this structure, which is seven stories in height. The building has an air of substantiality, so rarely found in structures devoted to exhibition purposes. The style of architecture is simple, though entirely in harmony with the details of construction and the surroundings. The outer walls are built of red brick, the inner of hollow fire brick. The superstructure of floors is constructed entirely of iron. The only inflammable material in the building is the wooden flooring and that is laid over a bed of cement. The extraordinary thickness of walls and the employment of heavy structural iron throughout the building make of it a marvel of stability and strength.



NEW YORK INDUSTRIAL BUILDING—VIEW OF AUDITORIUM.

The ground space covered by the building is 200 x 275 feet, and including its roof garden and auditorium it affords over 425,000 square feet of floor surface. Every foot of this is perfectly lighted—by natural light by day and by innumerable electric lamps and gas jets by night. Plenty of pure air is kept in constant circulation throughout the entire structure, and this with the excellent arrangements for heating gives it every requisite for a place for public exhibitions and entertainments. Four mammoth elevators —two steam, one hydraulic and one electric, having a total carrying capacity of 250 persons, run from the ground floor to the roof. The electric elevator was installed by the Sprague Electric Elevator Co.

The ground floor of the building is entered through a high arched corridor fronting Lexington avenue. To the left of the entrance is a restaurant and café, excellently managed, the cuisine of which is comparable to any in the city. Meals are served a la carte or table d'hote and at reasonable rates. On this floor are the offices of the building, reception rooms and one of the leading branches of the New York Palace Company.

THE EXPOSITION SPACE.

The second floor, or main auditorium, is admirably adapted to exposition purposes, combined with social, business and public functions, which have become distinguishing features of the meetings of the National Electric Light Association. There are over 55,000 square feet of floor space available on this floor, which by a most ingenious plan can be subdivided to suit.

The central section of this grand auditorium, which will easily accommodate 8,000 people, is surmounted by a glass dome 65 feet high and containing 12,000 square feet of glass, and its construction is such that it is one of the strongest and most perfect light-giving domes ever built. This makes the hall peculiarly available for day use, and at night prevents overheating, which is most desirable in a great ballroom or where other large concourses of people come together. The floor is smooth, and solid as the eternal hills, and the heating, lighting and ventilating appliances are perfect.

The third, fourth, fifth, sixth and seventh floors have been designed solely for exposition purposes. It is here that the greatest difficulties of construction have been overcome. The third floor has 40,000 square feet of surface available, and the fourth, fifth and sixth have each the same surface, making a grand total for exposition purposes, with the auditorium, etc., added, of over 425,000 square feet, which can be partitioned into sections of any desired dimensions.

PALM AND ROOF GARDEN.

One of the most attractive features of this building is the Palm and Roof Garden. The seventh floor has been utilized for this purpose. The floor is of cement and is absolutely fireproof. Over the glass dome, which gives light to the auditorium on the second floor, is the immense air shaft, and over this, from side to side, are steel beams. To these are affixed steel blades which are raised during the day to admit light to the dome, and at night they are lowered and overlap each other, making a floor as smooth, even and firm as that of the rest of the roof. It will then form part of the mammoth roof garden, which will cover 50,000 square feet and which will accommodate from 8,000 to 10,000 visitors. From it a magnificent view of portions of New York, Brooklyn, the harbor, and Long Island can be obtained. This roof garden is divided into three parts. On the Lexington avenue wing is the Roof Hall or Winter Garden. This is a covered auditorium well heated and well lighted. It is decorated with palms and other ornamental shrubs, and occupies a space 60x200 feet. It is covered with a dome 38 feet high with not a column to impede the sight. The stage is on the 43d street side.

GRAND CENTRAL R.R. DEPOT
N.Y. INDUSTRIAL BLDG.
F.A.Ringler Co N.Y.

NEW YORK INDUSTRIAL BUILDING—VIEW FROM LEXINGTON AVENUE.

THE LIGHTING PLANT.

The electric plant of this completely appointed exhibition building is one of the largest isolated plants in New York City. To avoid the heat which must necessarily be present in a basement power plant a separate building, situated on the corner of Depew place and 44th street, is used as a power and light generating station. The boiler room is below the street level and is fitted with four return tubular boilers of 150 H. P. each and the necessary feed water appliances. The dynamo room adjoins the boiler room but is on the ground floor of the building.

The engine equipment consists of one 300 H. P. and one 150 H. P. Fishkill Corliss, manufactured by the Fishkill Landing Machine Company, Fishkill, N. Y., and one 100 H. P. Skinner engine manufactured at Erie, Pa. The 300 H. P. engine drives two 80 K. W. Fort Wayne belted generators of the Wenstrom type. These are belted in tandem from a counter shaft. Three 45 K. W. Edison generators are driven by the 150 H. P. engine. A fourth 45 K. W. Edison generator is belted separately to the Skinner engine. The switchboard is of marbleized slate and is equipped with Weston instruments in the main and old-type Edison-Bergmann instruments in the feeder circuits. The mains are carried across 44th street by underground conduit and taken to the distribution center in the basement of the Industrial Building.

The division of units in the power station forms an equipment which is practically a duplicate plant Although but about 4,000 lamps are wired in the. building the generating plant has a capacity for over 6,000. The disabling of one engine would not necessarily cripple the plant, as the maximum load of the lamps now connected could safely be carried by the other engines. To provide for the rather remote contingency of a complete failure of the private plant, arrangements have been provided for connecting the complete interior wiring of the building to the street mains of the Edison Illuminating Company.

The wiring of the building has been done on the three and two wire systems. Brass-covered interior conduit, Grimshaw white core wire and the Edison-Bergmann type of porcelain cut-outs, etc., have been used. The arrangement of lights is such that a uniform illumination is secured over the entire floor space of the mammoth building. On the main or auditorium floor the lamps are clustered on artistic fixtures around the supporting columns and attached to three and five light brackets on the wall.

The auditorium proper, which is overlooked by balconies on the third and fourth floors, is lighted by seven cluster reflectors composed of 100 24-C. P. lamps each. The height of these fixtures is made adjustable by means of a hoist drum. There are over 2,000 lamps installed on this floor. Around the balcony walls, supporting columns and over the stage platform are group and cluster fixtures and rows of border lights which augment the effect of the central row of chandeliers, flooding the auditorium with a light as bright and mellow as that of noon-day. Scattered about the building are a number of low potential arc lamps situated at such points as tend to produce the best effects. It can truthfully be said that for purposes of exhibition no public building of New York City, or elsewhere, is better equipped with lighting facilities.

The complete electric plant was installed under the supervision of Mr. Marcus Nathan.

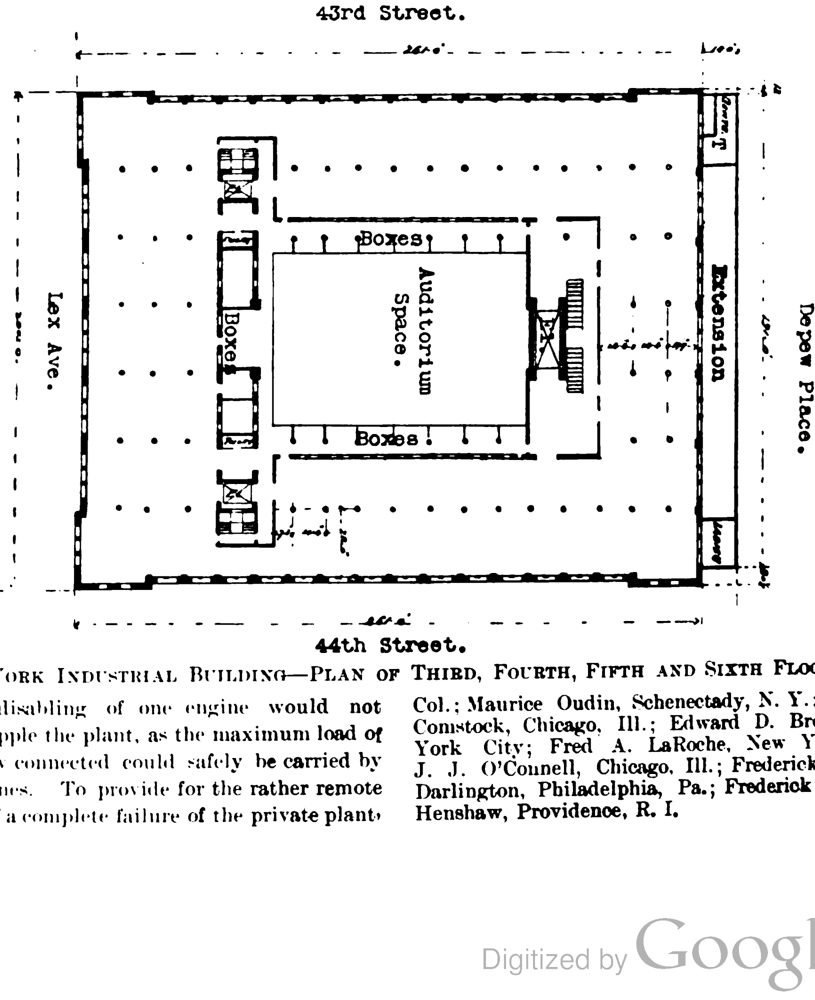
American Institute of Electrical Engineers

At the regular monthly meeting of Council held at the rooms of the Institute on November 20th the following associate members were elected:

Wm. D. Ball, Chicago, Ill.; Eskil Berg, Schenectady, N. Y.; Chas. L. Brown, Chicago, Ill.; Clinton C. Burr, Pittsburg, Pa.; Paul G. Burton, New York City; Julian Du Bois, Albany, N. Y.; Eugene Friedlaender, Duquesne, Pa.; Clarence P. Gott, New York City; Nevil Monroe Hopkins, Washington, D. C.; Albert S. Hubbard, New York City, Ellicott Maccoun, Munhall, Pa.; Fred'k William Phisterer, Ithaca, N. Y.; Erich Rathenau, Berlin Germany; Alfred K. Warren, New York City; Henry Storrs Webb, South Bethlehem, Pa.

The following associate members were transferred to members:

Arthur Hartwell, Pittsburg, Pa.; Julius Martin, New York Navy Yard; Joel W. Stearns, Jr., Denver, Col.; Maurice Oudin, Schenectady, N. Y.; Louis K. Comstock, Chicago, Ill.; Edward D. Brown, New York City; Fred A. LaRoche, New York City J. J. O'Connell, Chicago, Ill.; Frederick William Darlington, Philadelphia, Pa.; Frederick Valdemar Henshaw, Providence, R. I.



NEW YORK INDUSTRIAL BUILDING—PLAN OF THIRD, FOURTH, FIFTH AND SIXTH FLOORS.

VARIATION IN ELECTRICAL CONDUCTIVITY OF METALLIC WIRES IN DIFFERENT DIELECTRICS.*

BY FERNANDO SANFORD.

In a paper published in 1892, entitled "Some Observations upon the Conductivity of a Copper Wire in Various Dielectrics,"† I called attention to the fact that, with the copper wire used by me in the experiments referred to, the conductivity varied in different liquid and gaseous dielectrics by an amount approximating in some cases to 0.2 of one per cent. of its air resistance at the same temperature.

In a later paper, entitled "A Necessary Modification of Ohm's Law,"‡ I referred to a similar observation made upon the conductivity of a silver wire.

NEW YORK INDUSTRIAL BUILDING—GENERAL BUSINESS OFFICES.

The apparatus used in the experiments referred to in the above-mentioned articles consisted of a copper tube 120 cm. in length and 2.5 in internal diameter, closed at the ends with copper plugs provided with stopcocks. To the inside end of one end plug was connected a copper wire 1 mm. in diameter, which was stretched lengthwise through the center of the tube, and passed out through an insulating plug in the center of the other end plug. The resistance of the wire and tube was measured at various temperatures when the tube contained air, and again when the tube contained other liquid and gaseous dielectrics. A side tube midway between the ends of the long tube served to admit a thermometer, by means of which the temperature of the dielectric inside the tube and near the wire was measured.

Some fifteen different liquid and gaseous dielectrics were used, and, in general, the conductivity of the wire was found to vary from its air conductivity at the same temperature by an amount which was different for each dielectric used, and which was constant for any particular dielectric.

The accuracy of the observation was attacked upon both theoretical and experimental grounds (see especially *The Electrician*, London, of January 13, 1893, and Professor Henry S. Carhart in the *Physical Review*, Vol. I, p. 321), and though it had been verified by me with several different wires, and though I had collected considerable material bearing upon the nature of the phenomenon, I have thought best to publish nothing further upon the subject until the observation had been verified by some one outside of my own laboratory.

I have recently received a memoir by Professor Grimaldi and Dr. Platania, of the University of Catania,‖ giving the results of a long and very careful series of experiments upon the resistance of a copper wire in air and petroleum. These researches have been conducted with greater refinement and more delicate apparatus than have any previous experiments upon the same subject with which I am acquainted. The results show a degree of concordance quite remarkable when the difficulties of the determinations are taken into account. In every case the resistance of the wire in petroleum was found to be less than in air. This difference in resistance was, however, when reckoned as a percentage of the whole resistance of the wire, only about one-twelfth as great as in the case of the wire with which the phenomenon was first discovered by me; but the total variation in resistance amounted, taking the mean of all the determinations, to 0.00002 ohm, while in the same dielectric with the wire originally used by me it amounted to 0.00006 ohm. The wire used by Signors Grimaldi and Platania was 304 mm. in length and 0.22 mm. in diameter. Its variation in resistance per unit length was accordingly greater than in the wire used by me, while the corresponding surface exposed was less than one-fourth as great.

NEW YORK INDUSTRIAL BUILDING—LIBRARY.

The intelligence and care shown in the published work of Signors Grimaldi and Platania, and the remarkable uniformity of their results, make it improbable that the existence of the phenomenon will again be questioned.

The method and apparatus used in the following experiments were practically the same which I described in my former papers. The wires whose conductivities were to be measured were stretched lengthwise through the tube used in the earlier experiments, and were sometimes soldered and sometimes connected by means of a binding screw to the inner end of one plug, and were carried through the insulating plug at the other end of the tube. The resistance of the wire and tube was at first measured by means of a Hartmann & Braun resistance box and bridge, with bridge arms of 1 : 1000, the comparison coils being divided to tenths of an ohm. Later, a Nalder Brothers resistance box and bridge, with arms of 1 : 10000 was used, the comparison coils being divided to tenths of an ohm. The galvanometer used gave a noticeable deflection for a change in resistance of 0.00002 ohm, and later for 0.00001 ohm.

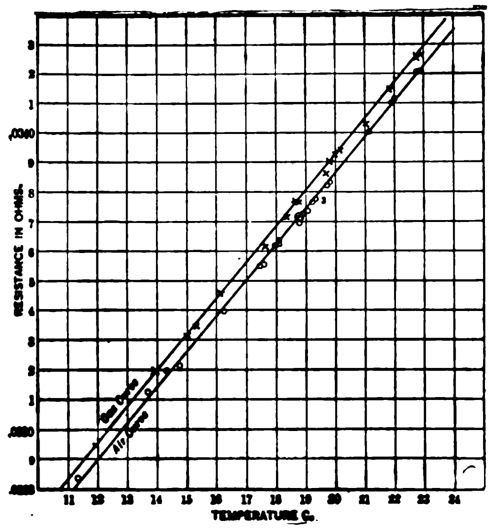


FIG. 1.

The temperature of the interior of the tube was measured by a standard thermometer graduated to 0.1°, inserted into the side tube with its bulb in contact with the wire, and read through a telescope which enabled the observer to estimate to 0.01° with a fair degree of accuracy.

---

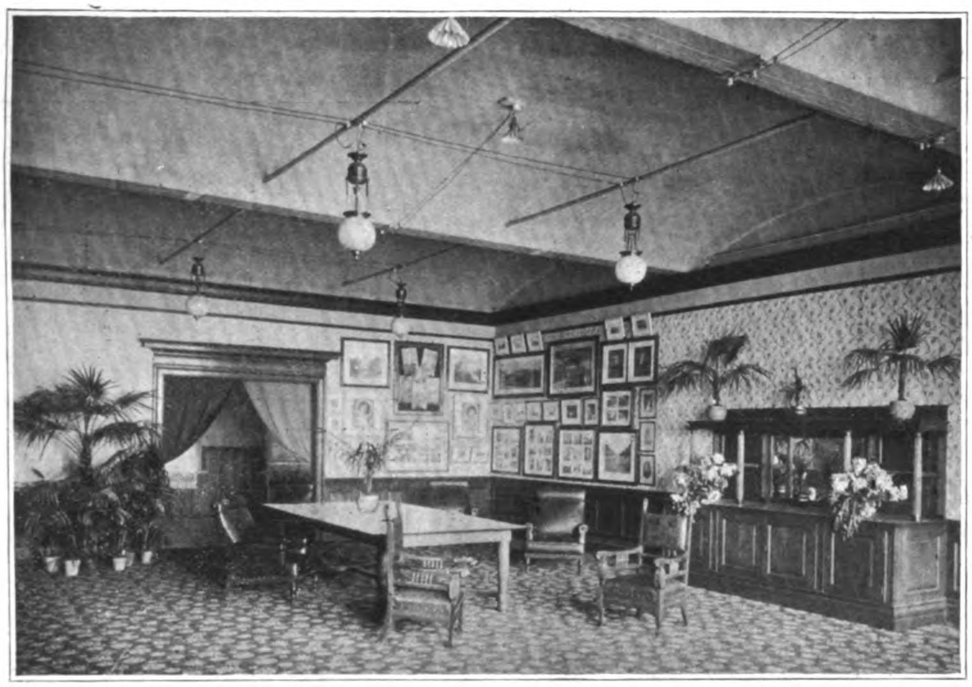
* From the *Physical Review*, Vol. III, No. 8.

† Leland Stanford, Jr. University Publications. Studies in Electricity, No. I.

‡ *Phil. Mag.*, January, 1893, Vol. XXXV, p. 65.

‖ Sulla Resistenza Elettrica dei Metalli nei diversi Dielettrici. Memoria del Dott. Giovan Pietro Grimaldi, Professore de Fisica nella Regia Universita di Catania, e Dott. Giovanni Platania, Assistente al Gabinetto di Fisica della stessa Universita. Parte I. Ricerche sulla variazione di resistenza del rame nel petrolio. See also, Dal Bollettino mensile dell' Accademia Gionenia di Scienze Naturali in Catania. Fascicolo XXXVIII, seduta del mese Dicembre, 1894. Also Nuovo Cimento July, 1895.

The wire first used had with the tube a resistance of 0.0335 ohm at 18° C., and a temperature variation of 0.000014 ohm for one-tenth of a degree centigrade. By reversing the current it was possible, even with the least sensitive galvanometer used, to estimate the resistance accurately to 2 in the fifth decimal place; and with the galvanometer used later an error of 1 in the fifth decimal place would not be made, even without reversing the current. This. while not the highest attainable accuracy in resistance measurement, is sufficiently accurate for the work, since the temperature of the wire could not be known with certainty to a greater accuracy than 0.1°. Had the measurements been made at a temperature differing greatly from the room temperature, or had the wire been perceptibly heated by the current, even this degree of accuracy would be improbable, since what was really observed was the temperature of the thermometer in the tube near the wire, and the small wires used would almost certainly change in temperature more rapidly than the thermometer. To guard against a possible error of this kind, the measurements were all made at the room temperature, which very rarely varied so much as 10° in twenty-four hours. The measurements were also made at all hours of the day, and sometimes late at night, in order that approximately the same number might be made with rising as with falling temperature.

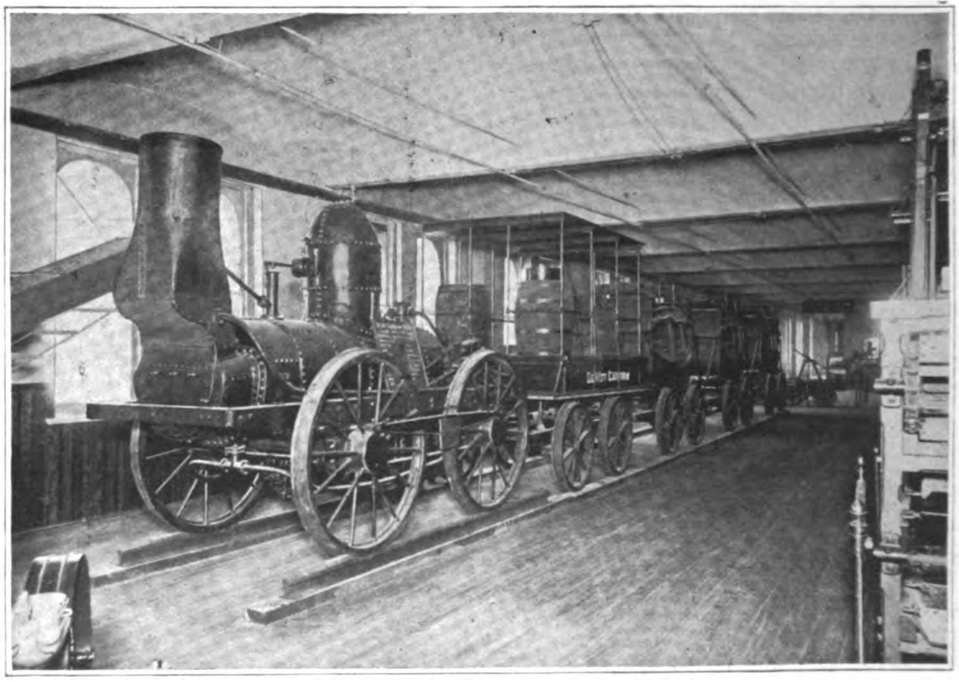


NEW YORK INDUSTRIAL BUILDING—CLUB ROOM.

To guard against the error due to heating of the wire by the current, the resistance of the wire at the same apparent temperature was observed for a wide range of current strength, and the current strength was kept far below the point where the resistance of the wire seemed to increase. The zero method of measurement was used throughout, and the current was passed through the wire only long enough to enable the galvanometer deflection to be read. In the first work, in order to secure a constant current strength, a battery of thirty-two silver chloride cells with high internal resistance was used with 100 ohms additional resistance in the battery circuit. Later, one Edison-Lalande cell was used with a resistance of from 50 to 100 ohms in the battery circuit.

That temperature fluctuations did not cause serious error may be seen from the data published with the first mentioned paper. The curve shown in Fig. 3 of that paper is reproduced here as Fig. 1. It represents the resistance of the wire in air, and in the gasoline burning gas used in the laboratory. There are twenty-six measurements made with the tube filled with air. These were made at irregular intervals for six days, the tube having been in the meantime filled with burning gas, and seventeen measurements made on three successive days with the wire in this dielectric. The tube and wire were neither disconnected nor moved in changing the dielectric. The gas was admitted through one of the end stopcocks, which was attached by a rubber tube to a gas cock in the laboratory, and was removed by blowing air through the tube with a bellows.

Of the twenty-six points platted for the air measurements, nineteen were made before the tube was filled with the gas, and seven were made before the gas had been removed. The greatest distance of any single air point from the curve corresponds to a resistance of 0.00002 ohm, or a temperature variation of 0.14°. In the seventeen measurements made with the tube filled with the burning gas, the greatest distance of any point from the curve corresponds to a difference in resistance of 0.000025 ohm or a temperature variation of 0.15°, while only one point in the seventeen is more than 0.00001 ohm from the curve.



NEW YORK INDUSTRIAL BUILDING—A CORNER IN RAILROAD EXHIBIT.

The average difference in the resistance of the wire and tube with the dielectrics named was 0.000058 ohm, corresponding to a temperature difference of 0.41°, while the nearest approach of any gas point to the air curve represents a difference in resistance of 0.00005 ohm, corresponding to a temperature difference of 0.36°.

That the temperature of the wire can be known with sufficient accuracy when the above precautions are taken is shown by the data published in the article by Professor Carhart, of which mention has already been made. In the investigation reported by Professor Carhart, a tube and wire combination similar to the one above described was heated up to 30° C. by warm water, and a series of resistance measurements was made while the temperature was falling to 20° C. Even with this arrangement, and with a thermometer reading only to half degrees, and a wire whose resistance varied by 0.000018 ohm for one tenth of a degree, the different measurements show a very uniform decrease of resistance for the estimated decrease of temperature.

I lay special stress upon this point, because in the editorial article in *The Electrician*, previously referred to, the writer charges that it is "a great assumption to suppose that the temperature of the wire is the same as that of the dielectric," and says: "The wire is, of course, being heated by the current, and a slight change of temperature would necessarily result from change of emissivity, owing to the different thermal properties of the various dielectrics used." This explanation would hardly have been offered had the author read with any care the article which he was criticising, since it would make it necessary to assume from the data there given that the temperature of the wire in petroleum was 0.43 of a degree *less* than in air, while in petroleum containing a little wood alcohol its temperature with the same current through it as before was 0.5 of a degree *greater* than in air. As a matter of fact, increasing the current strength fourfold did not alter the apparent resistance of the wire at the same temperature. In the very careful provisions made for maintaining the wire at constant temperature by Signors Grimaldi and Platania, this possibility of error was still further eliminated, so that it is certain that, whatever else may be the cause of the phenomenon, it is not due to a temperature variation of the wire.

(*To be continued.*)

ANOTHER PATENT SUIT.

The Elgin, Ill., Electric Illuminating Co., according to a local paper, has been notified by the General Electric Company that it is infringing one of the latter's patents by using the bridge circuit around a single dynamo and transferring switch.

It is understood that a rival manufacturing company will defend the suit.

The Storage Battery.*

A DISCUSSION OF ITS APPLICATIONS BY THE MEMBERS OF THE A. I. E. E.

PAST AND PRESENT OBSTACLES IN THE STORAGE BATTERY DEVELOPMENT.

BY CARL HERING.

The question which the engineer and constructor should discuss at present is not "Is a battery desirable?" but rather "Why is it that storage batteries seem to have been unsatisfactory?" And the question which concerns the capitalist is "Does it pay in dollars and cents to use the storage battery even if it is kept in a satisfactory condition by the makers?" Limiting ourselves to this country and judging in a general way from the number of storage battery installations, it would seem that the price at present (including of course the cost of maintenance) is such that in perhaps the majority of cases the margin of profit to the user is so small or so doubtful that it does not balance the supposed risk. The commendable practice of renting relieves the purchaser of this risk, which then leaves the question a mere matter of cost. A material reduction in the first cost and cost of maintenance would therefore at once turn the tables in many cases so decidedly in favor of the storage battery that there would be little doubt left as to the economy, and it would render the practice of renting unnecessary in most cases.

The chief reason why so few storage battery plants exist in this country seems to have been that the accumulator companies have for years been so busy fighting each other's patents and have spent so much money in this litigation that they have had neither time nor money left to manufacture and install their batteries. But all this litigation has now come to an end, thanks to an enterprising company which has bought up all the little life that is left of these historic "pasted plate" patents. This, together with the fact that it is now conceded by many authorities that for many if not most purposes the unpatented Planté type of cell is the better, removes the chief obstacle in the storage battery development in this country. As the patent question has now been settled and as cells of the Planté type have now been developed into practical forms, the storage battery outlook at present lies largely in the hands of the constructing engineer, and we should therefore look at the question from this standpoint.

To the user the five chief diseases of the accumutors appear to be: buckling, short circuiting, sulphating, disintegration and dropping out of the peroxide. Many inventors have thought that most of these may be made uninjurious by a process of opposing or resisting their disastrous effects, as distinguished from preventing their occurrence, although the term "preventing" has incorrectly been used to describe it. Buckling has been opposed by main strength and sometimes awkwardness; short circuiting by porous insulating sheets between the plates; falling out, by enclosing or locking the peroxide so that it cannot drop out, etc. Whether and how far such heroic methods have been successful can be determined only by tests. To attempt to prevent the almost irresistible force of expansion of the peroxide from exercising itself by confining the material in an inelastic lead frame, is a formidable, and it seems an almost hopeless task; the inevitable result is that one or the other must give way. If it is the peroxide, it will ultimately be crumbled by the pressure; if it is the lead, there will probably be buckling, or at least a separating of the contact surfaces at the subsequent contraction of the peroxide, and this inevitably results in the formation of that very objectionable layer of white sulphate which practically insulates the active material from its conductor, the consequences of which are sure to be fatal. The development of the storage battery has been greatly retarded by the fact that it was in the hands of mechanical engineers instead of chemists.

The careful constructor should attack the problem in a different way; he should go back to the beginning to find out the prime causes, and then prevent, if possible, these causes from arising, rather than to attempt to oppose their effect by sheer force and awkwardness.

What should be done is to try to construct the plates so that they are adapted to high rates without a great loss of efficiency or capacity. It will be found that in the majority of cases in which the storage battery would be of special value, it is a question of *rate* rather than *capacity*, that is, a great horsepower for a short time is more often required than a large quantity of energy delivered at a slow rate; it seems from a number of cases that any capacity above that which is obtained at a one, two or three hour discharge is generally of comparatively little value.

To study the effects of rapid discharges it must be remembered that the acid is as important as the lead oxides. When its density falls too low there will be a lowering of the E. M. F.; acid is withdrawn from the solution during discharge, hence the diluted acid in the fine pores of the active material must get out and denser acid must get in; but the only force which does this is the difference between their specific gravities, and as this is very small the force will be small and therefore the circulation will be slow, which in turn reduces the E. M. F. The chemical action will therefore be confined chiefly to the external surface, which is freely exposed to the acid, and the action then becomes so great per unit of surface, that white sulphating, or better, complete sulphating, takes place. If a rapid discharge is not to injure the plates nor lower the voltage by reason of the acid in the pores becoming too dilute, the circulation must be rapid; great porosity accomplishes this partly, but is attended by frailty and poor conductivity of the peroxide, which again results in a fall of the voltage. The ideal method would, therefore, seem to be a vertical lead plate to act as a good conductor with an extremely large surface and a very thin layer of peroxide on it, freely exposed to a large quantity of acid, which is capable of circulating rapidly. That such a plate may be made to have a greater capacity per pound of plate for rapid discharges and perhaps an equal one for slow discharges, as compared with the best thick, porous plates, has been shown by experiments.

In rapid charging the acid becomes too dense in the pores of a thick mass of active material if the circulation does not keep pace with the demand; this dense acid softens the peroxide and there is a tendency to form gases when the proper chemical action cannot keep pace with the current. Both the softening of the peroxide and the mechanical effects of the gases are injurious. The negative plates being soft and tough, are not so easily injured, but unless the acid can circulate very freely there will still be a lowering of the voltage like with the positive plates, and probably also a lowering of the ampere-hour capacity.

The contact between the peroxide and its conductor must be very good, for, if poor, then a white sulphate forms at the surface, which practically produces an insulating layer and disastrous effects are then inevitable. The peroxide will insist on expanding during the discharge and on contracting during the charge. It would be much better to accept this as an inevitable fact than to try to keep the material from obeying the laws of nature by forcibly confining it within an inelastic frame, as many inventors have attempted to do. To hold a large mass of active material firmly in contact with a lead conductor, when one expands and contracts while the other does not, or expands without afterwards contracting again, is a difficult matter. The best solution seems to be to have the active material in the form of an extremely thin layer over a large surface and formed from the lead itself, as this increases its adhering properties. If such a layer can be made porous, and if the surface is made up of small facets, there will be little tendency to buckling or scaling.

The gradual washing away of the surface of the peroxide, and the slow peroxidation and consequent disintegration of the lead support, seem to be absolutely unavoidable. Until some preventive is found, if it ever will be, it seems wisest to accept the inevitable and acknowledge that the positive plates are perishable. To use any other metals or carbon is out of the question; the addition of antimony to the lead seems to retard but does not prevent peroxidation. The favorite method of trying to avoid the effects of disintegration is to make the frames of the positive plates quite thick, thus prolonging their life. But such a method is certainly not satisfactory for cheap or portable cells, and the gradual washing away of the peroxide remains the same whether the frame is heavy or light, provided that the surface exposed to the liquid is the same.

But there is another way of meeting those unavoidable effects of use, which has recently been applied, and which seems to be a much more rational and effective solution of this vexed problem, at least when lightness and smaller first cost are desired. Instead of making the positive plates heavy and expensive, they may be made very light, cheap and easily replaceable; their life may then be shorter, but the battery will be as good as new whenever these perishable parts have been renewed. Their life is soon known to the user, and he can then readily determine for himself how much he must allow for amortization. But such a method, to be successful, requires that the old plates and sludge can be converted at a small cost into new plates; this it seems can now be done, and the writer believes that this alone will have a very important bearing on the outlook of the storage battery, at least for portable cells that are required for traction and many other purposes, or for both portable and stationary plants, if the first cost is an important factor. Such a method becomes practicable only when the chief factor in the cost of the plate is the material, the cost of labor and forming being small.

For stationary purposes, in which the only objection to the weight is the first cost of the lead, good storage batteries have been used abroad with success for some time, provided the rates of charge and discharge are kept low. Assuming that the same storage batteries may be made in this country as well, the question which affects the outlook here is then only one of the cost. But neither abroad nor here does there seem to be a battery in the market in which the weight has been sufficiently reduced and the rate sufficiently increased for a really successful traction battery, the success of which has been demonstrated beyond dispute. It is here assumed that to the public and to railway companies, traction batteries are not a demonstrative success until a traction company which has no affiliation with the accumulator makers finds it to his own advantage to use them in preference to other systems.

It seems to the writer that the only batteries which have a promising outlook for this very trying work are those which have a very large surface, very small depth of active material formed electrolytically, and a very free circulation of the acid. The lead frames should be made only thick enough for proper conduction, the batteries must be cheap in first cost, and the positive plates should be capable of being replaced comparatively frequently at small cost. They should be proportioned so that a discharge corresponds to one trip of the car—and only one. To claim as an advantage that a battery can run a car, say four trips, is mere deception, and to the intelligent engineer it is simply an admission that it can do no better. No one would think of carrying four relays of horses on a trailer of a horse car, and why should the equivalent be done with the storage battery unless it is that the battery can do no better and that it cannot be discharged rapidly enough so that the capacity and weight may be reduced to that required to run only one trip? The ideal is certainly a single trip discharge. If the rate for a four-trip battery could be increased four times without materially affecting the capacity, its weight and capacity for a single trip discharge would evidently need be only one-fourth as great. The charging rate should also be equal in hours to the discharge rate, or else it will take a plant of more than two sets of batteries to a car.

---

*Abstracts of communications read at the 101st Meeting of the American Institute of Electrical Engineers, New York and Chicago, November 20, 1895.

The objection to a plate with a thin layer of active material is that it may not retain its charge as well as one with a thick layer or pellets. but in most cases in which rapid rates are desired or cannot be avoided, the small loss in standing is probably more than balanced by the fact that the plates are not injured by rapid rates. As a rule, long periods between charges go hand in hand with slow discharges and less objection to great weight, while short periods between charges, high rates of discharges and lightness usually go together.

In conclusion the writer desires to make the following recommendations in the interests of engineers who may have to calculate accumulator plants :

The rates of charge and discharge be designated in *hours* and fractions, the current (or for power purposes, the watts,) during that time being considered to be kept constant. There can then be no mistake as to what is meant, as this represents the time in hours during which a cell will continue to give a practically constant current before the voltage falls below its limit.

That efficiencies and capacities be always accompanied by the corresponding rate in hours.

That in giving an efficiency it should always be stated whether it is for ampere-hours or for watt-hours.

That for portable batteries intended for power purposes the capacity be given in watt-hours instead of ampere-hours and that the weight given be that of the complete cell ready for use, as distinguished from the weight of the plates alone.

PERSONAL.

Mr. Henry Sachs, late manager of the Beacon Lamp Company, has accepted a similar position with the Colc & Gerald Manufacturing Company, makers of bicycles. It is one of Mr. Sachs's plans to induce electrical supply dealers to handle bicycles next season. With retail jewellers already in the field as bicycle agents, there seems to be no reason why any merchant should not add them to his stock.

Among our New York visitors this week have been Mr. George Redman and Mr. Charles Burns, of Rochester; C. P. H. Vary, of Newark, N. Y., and Mr. J. H. Rhotehamel, of St. Louis.

Mr. J. M. Hill, Chicago agent of the Columbia Incandescent Lamp Company, spent a few days in New York last week.

The Electrical Potentials.

The members of this prosperous social organization, which is the successor of the Boston Electric Club. dined together at Young's Hotel, Boston, on Monday evening, November 25. The paper of the evening was "The Insulation of Overhead and Underground Wires," read by Capt. Brophy and published in ELECTRICITY last week. The following gentlemen were present :

H. H. Daggett, Jr., Frank Mowbray, Attleboro, Mass.; Wm. L. Woodward, Providence, R. I.; A. A. Ziegler, R. F. Ross, A. T. Clark (American Circular Loom Co.), E. S. Garfield (Fort Wayne Electric Corporation), J. R. Orford (Boston Electric Light Co.), Percival J. Burgess, Eliot L. Caldwell (Edison Elec. Illuminating Co.), W. J. Denver (New England Telephone Co.), C. H. Holtzer and E. C. Newcomb (Holtzer-Cabot Electric Co.), T. H. Farnham (New England Telephone Co.), G. W. Blodgett (Boston & Albany Railroad), C. S. Sergeant (general manager West End Railroad), Henry F. Woods (purchasing agent West End Railroad), Frank Ridlon, Capt. W. Brophy (Assistant Commissioner of Wires), John R. Murphy (Commissioner of Wires), F. E. Barker, Josiah Q. Bennett, C. F. Pattison, C. B. Davis and F. M. Kimball (General Electric Company), W. E. Clark, G. W. "Happy" Adams, C. R. Fisk, R. A. Ripley, F. A. Swan, I. M. Mosher, Sidney Hosmer and Frank Brophy (Boston Electric Light Co.), W. S. Key (ELECTRICITY), W. H. Coughlin, C. S. Haley (General Electric Co.), H. S. Anderson, D. W. Dunn (Fort Wayne Electric Corporation), Boston; F. H. Raymond, Cambridge; H. H. Fairbanks (Electric Light Co.), Worcester.

GENERAL NEWS.

What is Going On in the Electrical World.

Clinton, Ia.—The "Herald" states that Prophetstown is to be lighted with electricity.

Middleburg, N. Y.—There is talk of building an electric road extending from Durham to Middleburg.

Norfolk, Va.—The electric car line to Lambert's Point is completed, and cars are now running daily.

Rockville Center, L. I., N. Y.—The trustees having given consent to erect poles and wires in the village, a company will be organized at once to put in a plant.

Bath, N. Y.—The New England Traction Company is going to apply for a charter for an electric road in Bath and to Hammondsport.

Birmingham, Ala.—The Birmingham Railway & Electric Company intends to convert its whole street railway system into electric lines.

Milwaukee, Wis.—The Milwaukee Street Railway Company is preparing plans for building an electric railway to Whitefish Bay early next spring.

Leonia, N. J.—A meeting has been held in favor of an electric road in this borough and a company is securing right of way. Leon Abbett, of Jersey City, is interested.

Groton, Conn.—A local manufacturer with sufficient steam power to generate all the electricity required by the business places of the village proposes to put in a plant.

Springfield, Vt.—The proposed electric road from Springfield to Charlestown, N. H., is receiving fresh attention, and there now seems a probability that it will be built.

Hillsborough, N. H.—The Hillsborough Electric Light & Power Company has got its plant in working order and is furnishing light for the streets and business places.

San Antonio, Tex.—The Citizens' Electric and Street Railway Company of San Antonio has filed an amendment to its charter changing its name to San Antonio Edison Company.

Atlantic City, N. J.—The councils of Holly Beach, Anglesea and Wildwood, on Five-Mile Beach, have granted a franchise to a trolley railway company to lay tracks along the beach.

Wheeling, W. Va.—A New York syndicate is negotiating for the purchase of the Wheeling trolley railway system, comprising about twenty miles of track, for a sum approximating $1,000,000.

New Orleans, La.—The ordinance granting a franchise to J. J. Cohn, M. Bier and associates for an electric lighting system in the city has been favorably reported by the council committee.

Independence, Mo.—The electric light plant owned and operated by the Western Electric Light Company of this city has passed into the possession of Charles Gudgell, as trustee of the bondholders.

Decatur, Ill.—John H. Culver of Decatur has been granted a franchise by the city council for an electric-light plant, to cost $10,000. The franchise is for twenty years and the contract with the city will be for ten years.

Cincinnati, O.—The Cincinnati Street Railway Company is building cars for its Walnut Hills line which are half closed and half open, that is, summer and winter cars combined. The new vehicles are much larger than the ordinary cars.

Salem, Mass.—A few evenings ago at the regular meeting of the Y. M. C. A. Congress the principal bill up for discussion was that providing for Welsbach gas lighting in place of electric lighting of the streets. The bill was defeated by one vote.

Santa Barbara, Cal.—The Santa Barbara Consolidated Electric Company, which holds franchises for electric roads to Carpenteria, will erect at Summerland a power-house sufficient for the needs of the line and for the local supply of light and power.

Wilkes-Barre, Pa.—The People's Electric Railway of Nanticoke and Newport, which connects Newport Township with Nanticoke, was opened for traffic last week, and the first car was greeted with cheers from crowds gathered along the line.

Johnstown, Pa.—A motor manufacturing company has made arrangements to remove to Johnstown as soon as the Pennsylvania Railroad Company builds a spur to the works. It is stated that the new works will employ 400 skilled mechanics.

Suffolk, Va.—The Suffolk street railway is likely to be purchased by Pennsylvania capitalists who propose to convert it into an electric line and extend the road to Lake Kilby and the Suffolk Fair grounds, thence to Smithfield, and in time to Portsmouth.

Detroit, Mich.—At the annual meeting of the stockholders of the Citizens' Electric Railway Company, held recently, the old officers were re-elected, as follows : Tom Johnson, president ; J. C. Hutchins, vice-president and treasurer, and J. C. Peters, secretary.

New Haven, Conn.—The reports of the four electric street roads of New Haven show that they are all doing a prosperous and paying business and that since the adoption of electricity as a motor they have increased their patronage as well as their usefulness to the city.

Lebanon, Mo.—The property of the Light & Water Company has been purchased at foreclosure sale by Edmon E. Crebs, of Fairfield, Ill., who represents the present holders of the bonds, amounting to $100,000. The property was knocked down to Mr. Crebs at his bid of $20,000.

Akron, O.—It is stated that Gen. Samuel Thomas and Calvin S. Brice, acting for a syndicate, have bought the Akron Street Railway and the Akron General Electric Company. The price quoted is $1,200,000. The road operates by trolley twenty miles of track in Akron and its suburbs.

Canastota, N. Y.—The Marvin Drill Company has just completed its first electric rock drill at its works here. The company has received inquiries from England, France, Germany, Norway, Sweden, Russia, Italy, Japan, Chili, Brazil, Cuba, South Africa, Mexico and Canada.

Amherst, Mass.—The board of trade has appointed committees to gather facts from neighboring towns relative to the cost, construction and management of their electric roads as a preliminary move toward establishing an electric line from Amherst to Sunderland, through North Amherst.

Chicago, Ill.—The Mutual Electric Light & Power Company, whose offices are in the Dearborn National Bank building, has made an assignment to Randall W. Burns. The franchise of the company and its plant are at Brainard, Ill., where it began business about three years ago.

Xenia, O.—The Rapid Transit Company of Xenia has contracted with the George H. Mellen Company of New York to build an electric road between Xenia and Springfield, twenty-two miles, work to be begun on February 1, the company to furnish everything and turn over the road ready for operation by the middle of next summer.

Baltimore, Md.—The Baltimore & Gunpowder Electric Railway Company has been granted a franchise for an electric railway beginning at the intersection of Monument street with the eastern limits of Baltimore and running thence east to Eleventh street, thence south to the Philadelphia Road, and thence along the Pennsylvania Road to the Gunpowder Falls.

Rochester, N. Y.—Proposals will be received at the office of J. Foster Warner, architect, 1036 Granite Building, Rochester, until December 17 next, for gas and electric light fixtures for the new Monroe County Court House. Designs must accompany all proposals, together with a certified check for $1,000. Proposals should be addressed to Lyman M. Otis, chairman building committee.

Kingston, N. Y.—Prominent business men in Port Jervis, Monticello and Ellenville have lately gone over the route of the proposed electric railroad connecting those places with Kingston, and are said to be convinced that it would be a profitable enterprise. The plan proposed is to build a freight, passenger and express line between Port Jervis and Kingston taking in the villages on the route.

Sauk Rapids, Minn.—At a special election held here recently for the purpose of voting $25,000 bonds to build a new dam across the Mississippi river to supply water power for an electric generating plant, etc., the issue was unanimously carried, there being not a single vote against it. A large paper mill will be built as soon as the dam is completed, and other manufacturing industries are talked of.

Buffalo, N. Y.—The board of aldermen have at last finished their work on the franchise for the Niagara Falls Power Company by modifying the conditions of the rejected instrument to suit the company in all but one particular, that retaining the power to annul the entire contract in case the company shall violate or fail to comply with any provisions of the grant for thirty days after notice from the board of works.

Portland, Ore.—A decree of foreclosure has been taken in the United States Circuit Court in the suit of the Mercantile Trust Company of New York against the Portland Consolidated Street Railway Company. The road has been operated by a receiver for the past year. The amount of the decree is $452,775, which comprises the consolidated bonds of the company, with interest. The railway system comprises thirty-one miles of electric road.

Niagara Falls.—The Niagara Falls Power Company, to meet the present and prospective demands for power, intends to immediately extend its wheelpit and put in three more turbines and as many dynamos. The wheelpit when completed will have room for seven more turbines and the extension of the power house to a corresponding size will afford room for seven more dynamos, making ten in all, or a total power from these ten turbines of 50,000 horse-power.

Shelton, Conn.—The Shelton Street Railway Company has been organized and will begin construction of its tracks through Howe avenue in Shelton and across the river to connect with the Derby street railway immediately. The capital of the company is $22,000 and the directors are Thomas L. Watson and Allen W. Paige of Bridgeport, W. J. Miller and D. S. Brinsmade of Shelton and W. S. Downs of Derby. General Watson has been chosen president and Mr. Paige secretary and treasurer.

Meriden, Conn.—At the annual meeting of the Meriden Street Railway Company, on the 25th ult., the formal transfer of the road to the New York, New Haven & Hartford Company was ratified. The price paid was $750,000.—Rumors are current here to the effect that the

Meriden, Waterbury & Connecticut River Railroad is to be equipped with electricity and that the Consolidated Company is seriously considering a plan to build electric roads to outlying towns and use them as feeders for their main line.

Reading, Pa.—All lines operated by the Reading Traction Company at present, including the Black Bear line and the Reading and Womelsdorf Railway, will be merged into the United Traction Company, and application for a charter for the new organization will be made on December 17. The names of the corporators are Wm. R. McIllvain, Henry C. England, James A. O'Reilly, Samuel E. Rigg and Oliver S. Geiger. The company will be capitalized at $400,000.

Stockton, Cal.—James Cross, manager of the Hobart estate, and others are interested in a scheme to supply Stockton with electric power, to be generated at South Spring Valley reservoir, twenty-four miles from here. The force from the water can be utilized without detriment to the mines. It will generate 7,000 horse power, which can be conveyed to Stockton and used for manufacturing and lighting purposes. The scheme is considered feasible by experts.

Ansonia, Conn.—Charles S. Mersick, as receiver for the Ansonia Electric Company, has been authorized to sell, assign, compromise, or in any way dispose of the uncollected accounts of that concern. The total of the uncollected accounts amount to $51,439.90 and more than half of them are considered to be practically worthless. There are claims amounting to $2,669 which are considered to be of some value, there is $4,507.19 involved in offsets, disputes and commissions and also $5,567.41 in litigation in Detroit.

Meadville, Pa.—The Meadville city council has granted to George D. Twain, who represents the Meadville Street Railway Company, a franchise of thirty-five years, for the operation of an electric street railway. The conditions are: The company is to complete six and a half miles of track within one year; to pay to the city. on its gross earnings, after five years, 1 per cent., after ten years, 3 per cent., and on the execution of the contract, to pay the city a cash bonus of $4,000.

Peoria, Ill.—The stockholders of the Consolidated Electric lines of this city have ratified the action of the directors at the recent meeting in arranging for consolidation of the two lines. Hereafter the two systems will be operated under the name of the Central Railway Company. The stockholders authorized the issuing of $750,000 bonds for the purpose of taking up the outstanding bonds and improving the road. The stock of the new company is owned principally by Columbus R. Cummings of Chicago, Walter Barker, J. B. Greenhut, Samuel Woolner, Jr., George H. Littlewood and other Peorians.

Montreal, Can.—It is stated that the Lachine Rapids Hydraulic & Land Company has secured the stock of the Citizens' Light & Power Company, and the Standard Light & Power Company, two companies which have very valuable franchises for the use of electricity in all its forms in Ste. Cunegonde and St. Henri, for street lighting in Westmount and St. Louis de Mile End, the lighting of the Montreal harbor, and the right to erect poles in the streets of Montreal. The Lachine Rapids Company is constructing extensive works on the shore at Lachine Rapids for the development of power for electrical transmission.

Utica, N. Y.—It is announced from Philadelphia that the entire issue of Empire State Light, Heat and Power Company fifty-year 5 per cent. consolidated mortgage gold bonds have been taken. The issue amounts to $3,000,000, of which $1,000,000 is to be held in escrow to retire underlying liens. Of the $2,000,000 to be sold, $1,000,000 goes to New York, $500,000 to Boston, and $500,000 to Philadelphia. The company will control by purchase the street railway and electric light companies in Utica, Whitestown (N. Y.) mills and New Hartford, N. Y., and will have an electric storage plant of 20,000 horse power capacity, the power to be received from Trenton Falls, N. Y.

Pittsburg, Pa.—On December 23 the proposed consolidation of the traction roads of Pittsburg will probably be consummated. On that day the Pittsburg, Duquesne, Central and Pittsburg, Allegheny and Manchester companies will hold special meetings at which the shareholders will be given an opportunity of voting on a proposition to lease the several lines and their franchises to the so-called Consolidated Traction Company for a period of 950 years. There is no doubt that the project will go through, and this will leave the Pleasant Valley, the Second avenue, West End and the Pittsburg and Birmingham traction companies in the field as independent corporations, the directors of these latter companies having declined to enter into a lease with the combine.

New York.—The Assembly committee appointed by the Legislature to inquire into the fiscal condition and the management and operation of street railways in the State were in session in this city during the week past and took the testimony of officials of several of the street railways, among them those of the "Huckleberry," the committee's report of which will be looked for with interest. Mr. Eli T. Langdon, of the Dry Dock, East Broadway & Battery Surface Railroad, told the committee that his company was only waiting for a fairly perfect system of electric motors to introduce the method on their road.—The Fourth Avenue Company (Vanderbilt) has two cars equipped with storage batteries running constantly on the Astoria Ferry cross-town line as an experiment; these cars have worked satisfactorily from the first trip, and the officials believe they have found a system that will continue to operate successfully.

TELEPHONE AND TELEGRAPH.

The Telephone in Maine.

The "Bulletin" of Madison, Me., thus tells of the "wonderful accommodations" which are furnished by telephones in the Pine Tree State: "Prof. Baker, of Brunswick, the whistler, singer and quick-witted coon, went to Bingham to give one of his street concerts when he was informed that a company at the Forks, which is twenty miles above Bingham, would like to hear him whistle. He secured the use of the telephone and after getting an order from the agent at Bingham to pay a specified sum he proceeded to send his shrill notes for a distance of twenty miles over the wire. The result was so satisfactory that he continued to entertain his unseen audience for some time, for which he realized a good sum."

A Verdict for Non-Delivery of Messages.

L. C. Hendershoot, of Ottumwa, Ia., has secured a verdict for $1,234 in a suit against the Western Union Telegraph Company. The suit was brought to recover the value of his race horse, which, he alleges, died for the lack of veterinary treatment which could have been given him had the telegraph company delivered promptly a message sent by the horse's trainer.

The independent telephone movement in central Pennsylvania seems to be in a healthy condition. The Home Telephone Company of Lewisburg is now building a line from Lewisburg to Mifflinburg. When it is finished a line will be built from Lewisburg to Milton and from Lewisburg to Northumberland and Sunbury. The Lykens Valley Telephone Company is now building a line from Uniontown in Snyder County, to Selinsgrove, crossing the river at Herndon. The Lykens Valley line connects Tower City, Williamstown, Lykens, Millersburg, Georgetown, Herndon and other towns. The two lines will be united at Selinsgrove. The officials of the two companies intend to extend the line to Williamsport, Harrisburg and Pottsville.

The Northwest Telephone Company is completing arrangements for the extension of its line from Fargo to Lisbon, S. D., in the spring. It is reported that the long-distance line is to be extended from Grand Forks to Grafton and Park River, and from Grand Forks to Larimore, and from Fargo to Tower City and Valley City. The proposed lines will give telephone communication from Fargo to all parts of the State.

George W. Cay and Martin Garrison are promoting the organization of the People's Telephone Company of New Haven, Conn., to compete with the service of the Southern New England Telephone Company in that city. Subscribers are being secured on the basis of $3 and $4 rates. The promoters contemplate similar organizations to Hartford, Meriden, New London, Norwich and the other cities of Connecticut.

Local capitalists of Grove City, Pa., have organized a company to construct a line from their town to the many surrounding coal mines and small hamlets, and finally centering in Mercer. Prominent men in Sharon and Greenville contemplate the construction of a line from their respective towns to Clarksville, taking in the small towns on the way, and from Clarksville to run it to Mercer.

Oakland, Cal., is trying to collect from telegraph and telephone companies an annual ground rent of $2 for each pole within the city limits. To fix the basis for the rent, the council passed an ordinance directing the companies to number their poles. This the companies neglected to do, and the police then counted the poles preparatory to a demand upon the companies for the rent. The companies will resist collection.

By the extension of the Rapid Telegraph & Telephone Company's line, now completed to Bethel, Vt., South Strafford, Strafford, Tunbridge, North Tunbridge, Chelsea, Royalton, Stoughton's Mills, East Bethel, Bethel and South Royalton are brought in direct communication, with reduced rates.

The Postal Telegraph and Cable Company is considering the extension of its telegraph line into Texas. President Chandler has recently made a tour of that State with this idea in view. The extension, if made, will be over 1,000 miles in length and include the principal Texas cities.

The Fulton Valley Telephone Company will extend its lines from Middleburg, through Fultonham, Breakabeen, Mackey and Broome Center, to Gilboa and Conesville, and from Breakabeen to Blenheim and West Fulton, and from Middleburg to Central Bridge, Conesville, West Fulton and Blenheim, N. Y.

The Bell Telephone Company makes a good instrument showing for the month ended November 20, coming within 36 instruments of September, which was the largest on record. Compared with a year ago, the gross gain was 8,624, and the net 8,984.

The county board of Menominee, Wis., has rejected the proposition of the Wisconsin Telephone Company to accept free of charge for one year telephones in the court house, jail and asylums. The Menominee Telephone Company, a local institution lately organized, has installed a new telephone system and secured the greater part of the old company's subscribers at a reduced rate.

The Logansport Mutual Telephone Company, Logansport, Ind., is preparing to make extensions to a number of surrounding towns. Royal Center and Deer Creek are to be first accommodated, and extensions will then be made to Winamac, Kewanna, Rochester and a number of other points.

Dr. Sawbridge, of Stephenson, Mich., is interested in the organization of a company for the establishment of a telephone line connecting Menominee with the villages of Wallace, Ingalls, Stephenson, Daggett, Talbot, Bagley, Caney and Nadeau.

Henry C. Wisner, a well-known attorney of Detroit, Mich., has filed a petition for a mandamus to compel the Michigan Telephone Company, the local Bell company to furnish telephone service at a more reasonable rate than is now exacted.

The director of public works of Philadelphia has been authorized to advertise for proposals for telephones and all wires where the city has its own circuit and no exchange service is needed. Over 600 'phones will be required.

C. W. Rickerd, general manager of the Willow River Lumber Company, New Richmond, Wis., has asked for telephone franchises in New Richmond and Hudson. The system when completed will connect New Richmond, Hudson, Stillwater, St. Paul and Minneapolis.

The township committee of Kearny township, N. J., refuses to grant overhead street rights to the New York and New Jersey Telephone and Telegraph Company, demanding that wires be placed underground.

The telephone war at Durham, N. C., between the Bell and Inter-State companies has reached that stage where Bell service is offered free of charge.

John M. Lennan has been granted a telephone franchise at Orlando, Fla. It is his intention to construct a long-distance service in that part of the State, making Orlando the central office.

The application of Hermann de Laguna for a telephone franchise at Pasadena, Cal., has been referred to the city attorney and the judiciary committee of councils for action.

W. E. Zeigler and C. A. Limmins are canvassing Gettysburg, Pa., with a view to establishing a telephone exchange. It is proposed to connect with Baltimore via Hanover and Westminster.

W. Z. Haight, of the Blue Earth Valley Telephone Company, of Winnebago City, is canvassing Mapleton, Minn., with a view to putting in a telephone exchange.

The Wisconsin Telephone Company has acceded to the demands of its subscribers in Milwaukee and will adopt a revised schedule of rates.

J. W. Walker will be manager of the new telephone exchange to be constructed at Florence, Ala.

The telephone system of Gainesville, Ga., has been purchased by J. M. Oliver, of Montgomery.

The council of Paris, Ill., has granted a telephone franchise to P. G. Furrow, of Cairo, Ill.

The Oak Telephone Company of Bloomingdale, Mich., will construct a line to Paw Paw, Mich.

Oxford and Henderson, N. C., are to be connected by a telephone line.

New Companies Incorporated.

The Pacific Coast Telephone and Electric Motor Company, Los Angeles, Cal.—to manufacture telephones, motors, etc., and construct and dispose of telephone and telegraph lines, etc. Capital stock, $100,000. Promoters: L. M. Gibson, W. C. Harrison, Jno. C. MacCabe, S. Weathercott, H. I. Lloyd, Los Angeles.

The Western Telephone Construction Company, Janesville, Wis. Capital stock, $5,000. Incorporators: W. F. Palmer, George S. Parker and T. A. Pipelow. The company will manufacture telephones and build and equip lines. The factory will be located in Janesville. T. A. Pipelow, of Milwaukee, will have charge of the work.

The Iowa and Dakota Telephone Company, Centerville, S. D. Capital stock, $25,000. Incorporators: J. E. Tomilson, W. A. Houts, and W. A. Cottrell.

The Pierce County Telephone Company, Wisconsin. Capital stock, $3,000. Incorporators: E. R. Condit, J. M. Johnson, T. E. Nelson and A. E. Michael.

The Crowley Telephone Company has been organized at Maple Rapids, Mich., with a capital stock of $2,200.

COMMERCIAL PARAGRAPHS.

George Cutter's street lamp fixtures are known wherever electric light is used. The latest candidate for favor in this line is the "Always Level" suspension streethood which is illustrated and described in a circular now being issued to the trade.

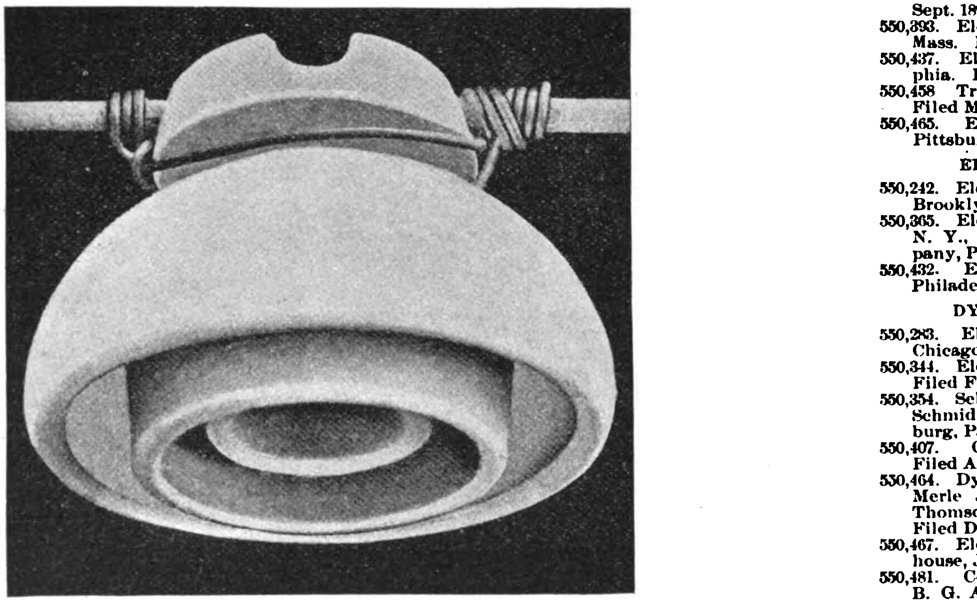
The *Columbus Lantern* of November 6 says: "The disposition of manufacturers of electrical apparatus to be well represented at the Ohio State University is typified in the recent action of the Standard Electric Company of Chicago. A year ago last May a 20 light arc dynamo was made especially for us from the latest designs. Since that time the company has improved the regulating apparatus used on the machine and has sent, without expense to us, the entire set of new parts necessary to adapt this new method of regulating to the old machine."

Southern Planters Interested in the Tesla Motor.

The Atlanta *Constitution* says: "The Westinghouse Electric and Manufacturing Company is giving some valuable suggestions to the planters of the South who feel more and more the necessity of some convenient and cheaper motive power to take the place of steam or, what is still worse, the horse. The Tesla motor at the exhibit of the Westinghouse Company is solving this problem for the farmers. Suppose a number of planters in the same community and residing near a water course should get together and utilize the water power to generate electricity. This would make the cost to each but nominal; not more than about $200. Now, with connecting wires, each planter could operate a motor on any portion of his farm to gin his cotton, shell his corn, saw his wood, or run any sort of machinery about the place. One Tesla motor could do all the work, and the cost, once the power station or plant was established, would be far less than the cost of steam and a thousand times more convenient. This matter is attracting the attention of the farmers who visit the Exposition and the Westinghouse Company will have done a great good for the South when it has introduced this motor on the plantations."

Insulators for High Potential Circuits.

It is admitted that high potential circuits are dangerous if not properly insulated. It is the opinion of Capt. Wm. Brophy, chief of the Boston Wire Department, that "the so-called insulating covering in use at the present time for high potential circuits is worse than a delusion and snare. Knowing the worthlessness of the material, it becomes necessary to use the best form of insulating supports. The present style of glass insulators is not what is required. Many of these insulators are only so in name. The very best grade of glass or porcelain should be used, and the double or single petticoat pattern, the form best suited to the purpose being that which will offer the greatest amount of dry surface between the wire and the supporting pin.



Locke's Triple Petticoat Insulator.

The qualities of an insulator deemed by Capt. Brophy to be essential for the purposes of high insulation are supplied in the Triple Petticoat China Insulator manufactured by Fred M. Locke, Victor, N. Y.

This Insulator is made from the highest grade chinaware in the world. It measures 5¼ inches in diameter and 4 inches in height, and has over 12 inches of surface between the wire contact and the supporting pin. About 10 inches of this surface is on the under side of the insulator, out of reach of direct rainfall, where it keeps comparatively dry. The surfaces of the bottom of the insulator are perpendicular, and therefore catch no foreign matter.

By repeated practical tests it has been found that a potential of 85,000 volts is required to puncture the insulator; hence it will carry with safety and economy any voltage that is practicable for use in commercial applications of electric power. The body and glaze of these insulators are of simple earths only, fused together into a vitreous, homogeneous mass at the greatest heat. No lead or other metallic oxide being used in making, the glaze is not a conductor.

These Insulators will not craze or crackle on the surface, or "leak," as insulators made of inferior material will do when subjected to variations of temperature. The ware used in the construction of these Insulators will stand severe tensile strains or heavy blows without injury, and will not crack or chip from the effects of high potential currents.

Heat, cold, dampness, acids, alkalies cannot act to disintegrate or otherwise injuriously affect the properties of the Insulator. The structure resists the action of gaseous and fluid substances as well as of other forces. No other insulator possesses, or maintains to such a high degree, all the essential qualities of high insulation resistance.

Many of these insulators are already in use on high potential long distance transmission lines and have uniformly given efficient, safe and satisfactory service.

INCORPORATIONS.

The Pittsburg and Monongahela Traction Company, Pittsburg, Pa. Capital stock, $12,000. Promoters: M. C. Bulger, Brownsville, Pa.; H. C. Johnson, Pittsburg; M. J. Eakin, Allegheny, Pa.

The Belleville Traction Company (Limited), Belleville, Can.—to establish an electric street railway in and about Belleville. Capital stock, $100,000. Incorporators: S. A. Lazier, T. C. Lazier, R. C. Lazier, S. S. Lazier and S. D. Lazier.

The Pottstown and West Chester Electric Railway Company, Pottstown, Pa.—to build and operate an electric railway about 22 miles long from South Pottstown to Buckton, Pughtown, to West Vincent, to the Eagle, to Lionville and to West Chester. Capital stock, $500,000. President, John P. Robinson, of Philadelphia. Directors: Arthur C. Ash, of Trappe; H. P. Clay, of Pottstown; Henry H. Robinson, Collegeville; Forrest D. Ash, of Spring City, and Joseph F. Ash, Trappe.

The National Electrical Exposition Company, New York City—to hold exhibitions of all productions of electrical and kindred industries. Capital stock, $10,000. Directors: Harrison J. Smith, Marcus Nathan, Robert B. Corey, Stephen A. Douglas, William F. Weise, William A. Stadelman, C. O. Baker, Jr., John A. Seeley and George F. Porter, of New York City.

The New York Gas Improvement Company, New York City—to purchase and develop real and personal property, including machinery, inventions and patent rights relating to the manufacture and production of gas or electricity, and to construct and equip buildings and machinery, and to lay pipes or wires. Capital stock, $23,000. Directors: Charles D. Lithgow, Emil Carlebach, John A. Snyder, Edward J. Kavanagh, Edward D. Phillips and P. F. Vaughan, of New York City.

The Bergmann Electric Company of New York City—to manufacture appliances to produce electricity, gas, steam, or heat, and to distribute the same. Capital stock, $500,000. Directors: Sigmund Bergmann, Harry E. Bailey, Edwin Lavens, Philip H. Klein, Jr., and Frederick La Roche, of New York City.

The Orange Mountain Traction Company has filed articles of incorporation at Newark, N. J. The company is to take the property of the Mountain Cable Company, which was recently sold by the receiver. The capital stock of the new company is $150,000. The corporators are Walter G. MacFarland and Leonard G. Dodge, of Philadelphia, and William S. Hood, of Camden, N. J.

The Woodbury (N. J.) Hygiene Ice and Manufacturing Company has filed articles of incorporation, and intends to offer to light the city with electric light in competition with the Woodbury Gas and Electric Light Company.

The Woodhaven Electric Light Company, Jamaica, N. Y.—to manufacture and use electricity for producing light, heat and power. Capital stock, $225,000. Promoters: Florian Grosjean, Brooklyn, N. Y.; E. M. Martin, Elizabeth, N. J.; A. J. Cordier, Woodhaven, N. Y.

The Allegheny and Evergreen Street Railway Company, Allegheny, Pa.—to build an electric street railway in Allegheny County. Capital stock, $30,000. Promoters: H. C. Bolster, Wm.L. Hartmeyer, J. C. Eckerman, Allegheny, Pa.

The Salida Electric Company, Denver, Col.—to furnish electricity for light, heat and power in Salida. Capital stock, $50,000. Promoters: Geo. A. Goddard, James E. Johnson, John Brennan, Denver, Col.

The Orchard Water Company, Kalama Wash.—to maintain and operate water works and electric lights in any town in Washington. Capital stock, $7,000. Promoters: H. Orchard, J. P. Atkin, A. H. Innis.

The Tacoma Auxiliary Fire Alarm Company, Tacoma, Wash.—to install electric auxiliary fire alarm systems in Pierce County, Wash. Capital stock, $30,000. Promoters: J. M. Bell, B. K. Worley, D. B. Worley, W. E. Theodore.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 26, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

550,319. Electric Tramway With Underground Distribution of Current. Alfredo Diatto, Turin, Italy. Filed Sept. 1894.

550,393. Electric-Car Truck. Louis J. Hirt, Somerville, Mass. Filed March 5, 1894.

550,437. Electric Railway. David Brooks, Jr., Philadelphia. Filed Feb. 28, 1894.

550,458 Trolley. Eugene L. Richter, Philadelphia, Pa. Filed March 27, 1895.

550,465. Electric Railway. George Westinghouse, Jr., Pittsburg, Pa. Filed June 13, 1890.

ELECTRIC LIGHTS AND APPLIANCES.

550,242. Electric Car-Lighting Apparatus. William Biddle, Brooklyn, N. Y. Filed March 7, 1895.

550,365. Electric-Arc Lamp. Frank Emery, New York, N. Y., assignor to the Standard Thermometer Company, Peabody, Mass. Filed April 22, 1895.

550,432. Electric-Lighting Gas-Burner. John M. Anck, Philadelphia, Pa. Filed March 29, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

550,283. Electric Mining-Machine. Edmund C. Morgan, Chicago, Ill. Filed Dec. 12, 1894.

550,344. Electromotive. Jean J. Heilman, Paris, France. Filed Feb. 13, 1895

550,354. Self-Exciting Constant-Current Alternator. Albert Schmid, Allegheny, and Benjamin G. Lamme, Pittsburg, Pa. Filed Aug. 24, 1891.

550,407. Commutator. John Dice, Wilkinsburg, Pa Filed Aug. 21, 1895.

550,464. Dynamo-Electric Machine. Elihu Thomson and Merle J. Wightman, Lynn, Mass., assignors to the Thomson-Houston Electric Company of Connecticut. Filed Dec. 2. 1889.

550,467. Electric and Fluid Locomotor. George Westinghouse, Jr., Pittsburg, Pa. Filed Feb. 5, 1892.

550,481. Controlling Apparatus for Electromotors. Jean B. G. A. Canet and Andre Hillairet, Paris, France. Filed Aug. 28, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

550,255. Apparatus for Hanging and Cleaning Telegraph or Telephone Wires. Alphons Custodis, Dusseldorf, Germany. Filed May 15, 1895.

550,260. Telephone-Circuit Signal. Mark A. Edson, Chicago, Ill., assignor to the American Bell Telephone Company, Boston, Mass. Filed May 20, 1895.

550,510. Telegraphy. Isidor Kitsee, Philadelphia, Pa. Filed May 25, 1895.

550,511. Telegraphy. Isidor Kitsee, Philadelphia, Pa. Filed Sept. 7, 1895.

BATTERIES.

550,480. Plate for Secondary Voltaic Batteries. William A. B. Buckland, London, England. Filed July 1[illegible], 1895.

550,534. Battery-Well. Jens D. Schreuder, Edgewood, and Simon H. Stupakoff, Pittsburg, assignors to the Union Switch and Signal Company, Swissvale, Pa. Filed Oct 25, 1894.

MISCELLANEOUS.

550,252. Commutator-Brush. Nellis M. Cross, North East. Pa., assignor of one-half to Charles A. Ensign, same place. Filed Oct. 29, 1894.

550,281. Tube, Pipe or Conduit. Robert H. Martin, Brooklyn, N. Y. Filed Feb. 28, 1894.

550,298. Electrically-Controlled Clutch Mechanism. John E. Stannard, Springfield, Mass. Filed April 5, 1895.

550,329. Electrical Pumping Apparatus. Gustaf Rennerfelt, Arvika, Sweden. Filed July 16, 1894.

550,330. Electric Pumping Apparatus. Thurs G. Rennerfelt, New York, N. Y. Filed July 3, 1895.

550,355. System of Electrical Distribution. Oliver B. Shallenberger, Rochester, assignor, by mesne assignments, to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed Oct. 12, 1886.

550,403. Electrodepositing Apparatus. Henry L. Bridgman, Blue Island, Ill. Filed Dec. 22, 1894.

550,411. Electric Switch. Thomas Harper, New Brunswick. N. J. Filed Aug. 29. 1894.

550,462. Register for Fire-Alarm Systems. Nathan H Suren, New York, N. Y. Filed Jan. 29, 1895.

550,468. Ventilating Means for Electrical Apparatus George Westinghouse, Jr., Pittsburg, Pa. Filed May [illegible] 1895.

ELECTRICITY.

Vol. IX. NEW YORK, DECEMBER 11, 1895. No. 22

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, President.
L. J. MONTGOMERY, Secretary.

Publication Office, - - 6 Park Place, New York.

Editors: { BURTON E. GREENE. R. H. WILLOUGHBY.

Business Manager, - - - JOHN L. GANS.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

An Urgent Necessity. That the condition of the electrical trade has undergone a marked improvement during the past year is beyond question. It is equally true that the measure of this improvement has been much less than it would have been if all the leading companies had been managed in the interests of stockholders and with sound common sense. If there is one company which has failed to secure any benefit from better general conditions, it is the General Electric Company. And this company, being the largest one in the country, with its slovenly or corrupt management is the only apparent stumbling-block which prevents this trade taking its place near the head of the procession of prosperous American industries. If the interests of the G. E. Company were the only ones to be injured by the policy pursued, the subject would not be worthy of comment. But this is not the fact. They are the pacemakers. They do a larger business than any other company. They make and sell in greater or smaller quantities about everything needed in the railway or lighting business. They virtually make prices. Though other companies may get perhaps 10 per cent more in competition it is almost entirely the fault of the G. E. management that prices are not at least 25 per cent. higher. It is only a few months indeed since in official circulars they announced an average reduction of 25 per cent. on small supplies, in face of the fact that with the general recovery of business prices of iron, copper and other raw material had been advanced.

If it is argued that the G. E. Company is doing a big business, it is admitted. But to whose benefit? Certainly not to that of the stockholders. The only apparent benefit in the present conduct of that business accrues to the small coterie of salaried schemers who direct its affairs but who pay no share of the losses.

The troubles in that company are deep-seated, and will require the concerted action of the stockholders before they are cured. Nothing less than a revolution in management must occur, with the dismissal of every man holding high position there to-day. A house divided against itself cannot stand, and no business concern can endure whose control is intrusted to various cliques of malcontents, each working for his own ends, without harmony, without an able or authoritative central head. In the G. E. Company there is nothing but petty intrigue, jealousy and contention for place. As the formation of the company itself was a grand conspiracy against the electrical trade of America, so its management has descended into a series of petty conspiracies, one against the other, each with the same object in view. In this we do not refer to the Board of Directors, but to the officers, from the president down to the heads of departments. Each one is after the scalp of the man above him, and no trick is too mean when there is any hope of success. Several of the pigmies have agreed that the president ought to be displaced. There the argument ends. Each thinks that he is the man for the place. Conspicuous aspirants for this position are Messrs. Ord and Darling. This internal warfare has gone so far that one man hires detectives to watch his rival, and the private detective agencies of the city have reaped quite a harvest.

It should be obvious to the stockholders that the condition of their property cannot improve materially as long as the present state of affairs exists. It is for them to determine what shall be done. There can, however, be no half-way measures. The remedy must go to the bottom of the difficulties. It must begin at the top, but not end there.

Charles A. Coffin must go. He has showed his utter unfitness to manage a large manufacturing enterprise. Whatever power he ever had for good has been destroyed, and his capacity for evil on the outside of the company has been greatly overestimated. He could never again gain a foothold in this trade. Any company taking him up would be marked for certain destruction. The man and his methods are too well known. He would have to devote his talents to some other line of business.

The company needs a strong central head. The man cannot easily be found, but he must exist. The requirements are peculiar, but not impossible.

The diverse and sundry committees must be abolished. Every one of the officers and employés who has been engaged in the petty intrigues of the past two years must go with Mr. Coffin, or follow him quickly; new blood is needed.

The intrinsic value of the stock becomes less and less the longer the maladministration of affairs continues. Interest can never be earned on the present capitalization but with a proper reduction, and with a strong management the property would soon be turned into a paying one. Every company in the field would thereby be benefited, but the greatest benefit would be to the G. E. Company itself.

The revolution is inevitable. The sooner it comes the sooner will the ill-repute of the company in the trade be removed, the confidence of the press be restored, the securities of the concern again command some measure of respect, and the stockholder obtain some return on his investment.

* * *

If the Standard Telephone Company has any more patents it desires illustrated, it can send in its lists. Electricity is the best read trade paper in the world, and reading notices of this nature cost nothing.

More Lamp Litigation. Most of our readers will be surprised to learn, on reading this week's issue of ELECTRICITY, that further injunctions have been granted in favor of the General Electric Company against an independent lamp manufacturer. While the General Electric Company had made many boasts after the expiration of the fundamental Edison filament patent that there were many detail patents in reserve which could still be used to suppress competition, no one posted in incandescent lamp manufacture had taken much interest in the subject, knowing that there was nothing left of any value in the way of patents on the incandescent lamp, and that whatever suits might be brought by the General Electric Company would be brought simply for the sake of annoyance and with no expectation that competition could be killed.

We reproduce this week the full text of the patent upon which an injunction has been granted, with illustrations. This is done, not because the subject merits particular prominence, but to allay the fears of such of our constituency as have not ready access to the facts. The patents cover nothing of importance. and it is doubtful if any independent lamp factory in the United States is infringing them. They cover details of manufacture which have long since been superseded by the makers of the best lamps by other and better processes. The methods covered are still used in the Harrison lamp works, but it is well known to every user of incandescent lamps that the Edison lamp of to-day is not the best lamp on the market, and it is admitted by everyone except the General Electric people themselves that it stands fifth or sixth in the field. It is extremely doubtful that the patents could have been sustained if a thorough defence had been set up, but the facts are that the patents were not worthy of any defence, and we do not see why the Bryan-Marsh Company should be particularly criticised for allowing a judgment to be taken by default. We do think, however, that this company would have used good judgment to have advised the trade through the press when this suit was brought as to just what the action comprehended.

That the Bryan-Marsh Company do not attach special importance to the decision recorded against them is shown by the following statement of Mr. Converse D. Marsh, president:

"Three days before we received notice of the suit we had discontinued the use of the methods described in these patents, because we found them to make unsatisfactory lamps. But until we received formal notice of infringement from the Edison Company, we did not know that the method of securing a filament from the inside of a lamp was patented. However, the whole matter was of no importance, as the Edison Company readily agreed to take judgment and waive damages, they paying all the costs of the action.

"The judgment in no wise affects us or our customers, as the $1 damages awarded the Edison Company covers the entire matter."

* * *

No Trolley Monopoly Yet. The decision of Judge Townsend in the suit of the Thomson-Houston Electric Company against the Winchester Avenue Railroad Company, sustaining the validity of patent No. 495,443 and invalidating patent No. 495,383, will doubtless prompt the General Electric Company to claim a monopoly of the under-running trolley system in this country. Indeed it would seem, at first thought, that the decision in this suit affords ample ground upon which to base such a claim. But such an assumption can be properly made only after certain other conditions are fulfilled.

Should the New Haven decision be sustained by the higher courts, it will certainly mean that those roads now operating without licenses from the General Electric Company will be compelled to either abandon the present form of trolley or to pay a royalty for its continued use. An appeal is to be taken, however, and it is the opinion of able legal talent that Judge Townsend may be adjudged to have been in error when he so broadly sustained the claims of patent No. 495,443. In the event of the decision being affirmed, those roads not licensed by the General Electric Company need not render their tribute to Cæsar, having, as they will, recourse to the use of other forms of trolley not covered by the patent in suit.

If the somewhat remote, if not impossible, contingency implied by a failure to invent a non-infringing trolley should arise, there yet remain other efficient methods by which current can be supplied to the motors of a moving car, none of which come within even the broad scope of any of the claims of the Van Depoele patents. Of one of such devices ELECTRICITY said in its issue of May 29:

> Reference is here made to the flexible sliding contacts usually mounted in the form of a parallelogram on the top of the car. One great advantage that this form of contact has is that it does not lose contact with the wire and that upon reversing the direction of the car it is not necessary to pull down the trolley, reverse its position and then adjust it to the conductor. In fact, we have often wondered that this device, so well and favorably known abroad, has not been adopted here to the exclusion of the devices with which we are familiar.

It has not frequently occurred that we are compelled to go to Europe for mechanical or electrical ideas of any kind, but when forced, either by restrictions of patents or other circumstances of trade, to borrow from our neighbors on the other side, Yankee ingenuity has always found abundant opportunities for improvement. The European form of trolley, improved to suit the local conditions of traffic in this country, would certainly prove quite as efficient and satisfactory in American service as it has abroad.

In any event, a trolley monopoly, even if established through protracted litigation, cannot be made effective, nor can it be long continued.

* * *

Electricity Direct From Heat. A careful perusal of Mr. Leon Le Pontois's interesting paper on "The Inefficiency of the Direct Methods of Converting Heat into Electricity," concluded in this issue, leads rather than forces one to accept as correct the author's conclusions "that it is not very likely electricity will ever be obtained, efficiently. from heat," and "that after all the most economical solution to the problem lies in the construction of a more perfect heat engine, driving the already highly efficient dynamo."

Able and distinguished scientists and experimenters have given much careful thought to the problem; but so long as it remains seemingly impossible to devise any apparatus, or to employ any process by means of which no more than 2 per cent. of the heat energy of any combustible can be converted into electricity without the aid of intermediary devices, this method of conversion will certainly not extend its usefulness beyond the realm of laboratory experiment. As interesting as it may be to follow the researches of the investigators in this field, the results attained by them must at last be judged from a commercial rather than a scientific standpoint. By this standard any energy-converting device having an efficiency of 2 per cent. or less becomes useless for any of the purposes of this eminently practical age.

In view of the unsuccessful attempts already made, it would seem that the science of thermo-electricity has reached a stage of development beyond which it is not possible to go until some more efficient process of conversion has been discovered. When it is found what electricity actually is, or when the true relation existing between electricity and heat becomes known, a commercial solution of the problem of converting the latter into the former by direct methods will doubtless be accomplished.

"The Evolution of a Technical Journal."

(From W. J. Johnston's latest brochure.)

ELECTRICITY has become a necessary part of daily life. Every branch of human industry has come more or less within the range of its columns.

Under the Searchlight.

Views and Opinions on Timely Topics.

STRANGER *things have happened than that Henry Villard should succeed Charles A. Coffin in the presidency of the General Electric Company. Mr. Coffin has already announced to Mr. Villard personally that he would cheerfully retire in the latter's favor. Mr. Villard has time, ambition, power to raise money. Why should he not take it into consideration?*

* * *

Asks Advice of Congress in the Berliner Case.

In his report of the operations of the Department of Justice for the last fiscal year Judson Harmon as Attorney General asks Congress to direct him what to do in the Bell telephone litigation. The expense of this case, he says, is very heavy. It will take six months to prepare rebuttal testimony. He favors continuing the case to a final decision, providing the expenses can be met, and says:

"If the people have been deprived of their natural rights by the improper issue of a patent, as the Government avers, it would not be a proper course on its part to discontinue litigation which has probably been purposely protracted until the patents have expired, but such litigation should be persisted in to establish, for the sake of future action on its part, its right to sue to annul patents."

* * *

ELECTRICITY offers as a suggestion to some one of the lamp companies that at the Grand Electrical Exhibit of 1896 a drawing-room be fitted up to show the possibilities in effects with concealed lamps. Any good concern in the business would cheerfully do the glass work without charge, and any one of a dozen furniture establishments would supply the furnishings and draperies on the same basis. Would not such an exhibit attract the attention of many a householder in the larger cities, and show that the highest triumphs in artistic lighting are reserved for the electric incandescent lamp?

* * *

Some Reasons Why Supply Dealers Complain of Low Prices.

(From New York Department Store Advt.)

Electric Call Bell Outfit.—We offer this entire outfit with full directions so simple that a child can put it up, all complete for 98 cents.

Dr. ——'s Medical Battery, one of the finest batteries manufactured, in a handsome polished oak case, convenient and most reliable, metal parts handsomely nickel-plated, with complete set of fittings; regularly sold at $6.00; special, $3.98.

If you want to catch the worm buy one of our "Early Bird" Electrical Alarm Clocks, mounted on handsome polished oak cabinet, complete with battery; formerly sold at $5.50; special $2.98.

* * *

FROM the Richmond (Va.) papers we learn that during the progress of the fight for a franchise in that city between the Home Telephone Company and the Standard Company agents of the latter telegraphed to the editors of the *Electrical World* and the *Electrical Review*, asking their opinion of the standing of ELECTRICITY. Both these gentlemen replied that they had no opinion to express. This is characteristic. Neither one of these esteemed contemporaries has ever been known to have an opinion on any subject. At the same meeting of council letters were read from the following gentlemen expressing the opinion that ELECTRICITY is a paper of very poor standing: Morris Hunter, Richmond, Va., Secretary Old Dominion Construction Company; C. W. Winston, Richmond, Va., Secretary and Treasurer Electric Construction Company and Home Electric Company; A. Pizzini, Jr., Richmond, Va., President Electric Construction Company and Vice-President Home Electric Company; M. W. Thomas, Richmond, Va.

General Manager Old Dominion Construction Company.

We cannot claim the pleasure of the acquaintance of any of these gentlemen, and as Mr. Toots said to Capt. Sol. Gills, we do not see how they ever can know us *without* giving us the pleasure of their acquaintance.

* * *

Has Not Sold to the Bell Company.

A statement was recently made in the columns of the *Commercial Appeal* of Memphis, Tenn., to the effect that the Memphis Telephone Company, which in August contracted with the American Electric Telephone Company of Kokomo, Ind., for a $100,000 plant, had sold its rights to the Bell Company. The matter being brought to the attention of the American Company, the following denial was made by Paul W. Bossart, Assistant General Manager:

"There is no truth whatever in the statement that 'the Bell Company has bought the Kokomo claim in Memphis?' Preparations are being made to prosecute the work under contract."

* * *

LORD DUNRAVEN, the ex-yatchsman, widely known in literary circles as the author of "Explanations which do not Explain," has, it is rumored, instructed a New York attorney to institute proceedings under the copyright laws against Thurlow Weed Barnes. It is alleged that the title of the distinguished English author's most recent production has been appropriated without consent or credit by his American contemporary, whose facile pen has already produced two installments of his highly interesting work of creative and imaginative writing.

"Electricity" finds Mr. Angell.

To the Editor of ELECTRICITY.

SIR: In this week's issue of your paper I notice a request for my address.

You may say to your correspondent that I am on the road most of the time and will be at this hotel address until Thursday next, where the party can communicate with me if desirable.

At Hotel Burns, Syracuse, from 12th to 15th.

The value of your paper is demonstrated in this instance. Yours truly,

F. H. ANGELL.

The Avery, Auburn, N. Y., Dec. 9, 1895.

The Standard in Congress.

Senator Gorman has introduced in the Senate a bill to authorize the Standard Telephone and Telegraph Company of Baltimore and Washington to operate and maintain a plant and exchange in Washington.

* * *

ONE of the funniest things which Mr. Thurlow Weed Barnes has said is that the criticisms of his company have emanated from the Bell Company. We suppose the Bell Company would gladly swap off its best patents for the assurance that there would be a company just like the Standard started every month. Nothing would be surer to prolong the life of the Bell monopoly.

* * *

Free Telephone Service.

(From the Providence Journal.)

That it is neither impossible nor necessarily dangerous beyond the actual risk to capital invested, to bring the Bell Telephone combination to terms is seen by the report from Durham, N. C., where the Inter-State Telephone Company has pressed its competition to such a critical point that the Bell Company has offered instruments to the public free of charge.

The Oft-Recurring Rumor.

(From Town Topics.)

For the twentieth time a pool has been formed in General Electric, with a view of putting that stock well in the 80s. I hope that on this occasion success will perch upon the banner of those who are expending such force in trying to *shock* the bears on General Electric.

Westinghouse Wins and Loses.

THE UNDER-RUNNING TROLLEY.

One of the Van Depoele Patents Declared Invalid; Another Sustained.

Judge Townsend, of the United States Circuit Court at New Haven, Conn., on the 7th inst., rendered a decision in the suit of the Thomson-Houston Electric Company vs. the Winchester Avenue Railroad Company, declaring one of the Van Depoele under-running trolley patents in suit to be invalid and sustaining the other.

At the time this suit came up for final hearing, in May last, ELECTRICITY devoted considerable space to a review of the case, thereby acquiring all the distinction which comes to the only electrical journal having enterprise enough to go after and to get important and interesting news. As will be remembered, the suit in question is based upon two patents issued to Charles J. Van Depoele, which it was broadly claimed covered the under-running trolley as now used in electric traction work. These patents became the property of the Thomson-Houston Company, and later of the General Electric Company. The defendant in the suit is a licensee of the Westinghouse Electric and Manufacturing Company, hence the contest was in reality between the General Electric and Westinghouse companies. As the case now stands, the honors are about evenly divided.

The patents upon which suit was brought are Nos 495,383 and 495,443, both bearing date of April 11, 1893, although the former was filed June 18, 1888, and the latter March 12, 1887, the delay in issue being caused by interference with the applications of R. M. Hunter, Frank J. Sprague and others. Of these patents, No. 495,443 was deemed to be the stronger, as it was certainly broader in its claims. Of the sixteen claims under this patent only the 6th, 7th, 8th, 12th and 16th were at issue. The broad character of the patent is illustrated by the 6th claim, which is as follows:

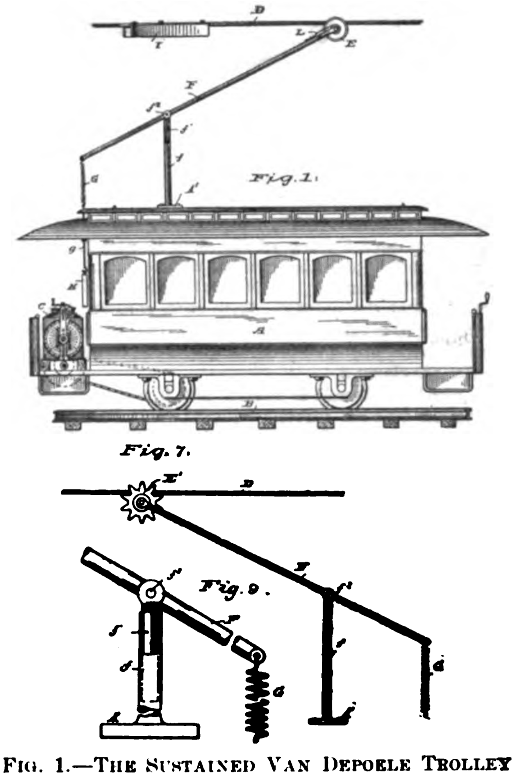

FIG. 1.—THE SUSTAINED VAN DEPOELE TROLLEY PATENT.

6. In an electric railway, the combination with a suitable track and a supply conductor suspended above the track, of a car provided with a swinging arm carrying a contact device in its outer extremity and means for imparting upward pressure to the outer portion of the arm and contact, to hold the latter in continuous working relation with the under side of the supply conductor, substantially as described.

The accompanying illustration, Fig. 1, is a reproduction of the drawings forming a part of the specification of patent No. 495,443.

Patent No. 495,383 was, specifically, for an improvement upon the system broadly claimed by patent No. 495,443. In the suit but three claims of the former patent, to wit, the 11th, 12th and 13th, were involved. These claims are as follows:

11. In an electric railway, the combination of a car, an overhead conductor, a standard on the car, a rotating support thereon, an inclined contact carrying an arm hinged upon said support and a tension spring secured so as to rotate with the support and acting upon the said arm for holding the contact device in position.

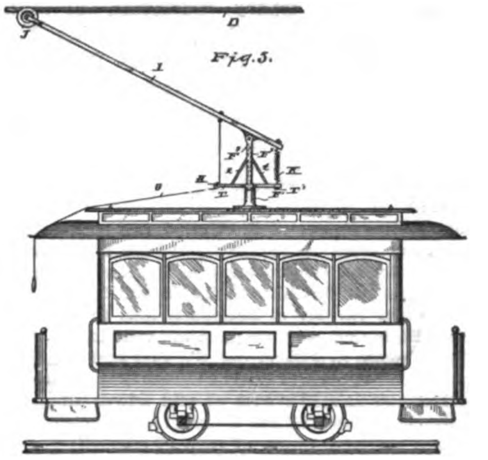

FIG. 2.—THE INVALIDATED VAN DEPOELE TROLLEY PATENT.

12. In an electric railway the combination with a car of a standard on a car, a rotating support thereon, an arm hinged upon said support and provided with a grooved or flanged contact device for engaging with a suspended conductor, and a tension spring secured so as to rotate with the support and acting upon the said arm to hold the contact device in position.

13. A reversible contact device for an electric railway vehicle, consisting of a standard, a rotating support thereon, a contact carrying arm hinged upon said support, and a tension spring secured so as to rotate with the support and acting upon the contact-carrying arm for holding the contact device in position.

The construction and arrangement of a trolley constructed under the specifications of patent No. 495,383 is shown in Fig. 2.

In defence it was claimed that both patents had been anticipated by several prior American and British inventors, among whom were Daft, Sprague, Wesson, Fitzgerald, Parish & Munn, Heald, Smith, and others.

Patent No. 495,443 was asserted to be void because the same invention was disclosed in previous patents to Van Depoele. The answer to the defence denied that any of the patents issued prior to No. 495,383 covered the essential features of the patents in suit. It was claimed that there was nothing in the state of the art at the time patents Nos. 495,383 and 495,443 were issued that would suggest the invention embodied in these patents.

Judge Townsend's decision is a voluminous one, covering twenty-five closely typewritten pages. Patent No. 495,443 is broadly sustained, the judicial conclusion being thus tersely expressed: "Utility is conceded. Infringement is proved." In substance the decision declares that patent No. 495,383 is invalid for want of practicability. It is therefore ordered that "a decree be entered for an injunction and accounting as to the claims in patent No. 495.443, and dismissing the bill as to patent No. 495.383."

An appeal from Judge Townsend's decision will be taken.

A suit involving practically the same patents is now awaiting decision in the United States Circuit Court for the Southern District of New York, the evidence having been presented and arguments made some weeks ago. The litigants in this case are the same as in the New Haven case, although the title of the suit is Thomson-Houston Electric Company vs. the Elmira & Horseheads Electric Railway Company.

The "New Books" department of the December *Review of Reviews* is crowded by the holiday publications, but contains brief reviews of the best literature of the season. The department is fully illustrated.

Lamp Litigation.

ANOTHER INJUNCTION GRANTED.

Patents Out of Date and a Decision of No Value.

There was filed in the Circuit Court of the United States for the Southern District of New York, in the Second Circuit, on the 3d inst., a decree by Justice E. Henry Lacombe granting a perpetual injunction to the Edison Electric Light Company and the Edison General Electric Company, restraining the Bryan-Marsh Company, 136 Liberty street, New York, from infringing Letters Patents Nos. 242,896 and 353,883, for improvements in incandescent lamps. The following is a full text of the decree :

It is, on motion of Dyer & Driscoll, complainants' solicitors herein, Cochran & Tomlinson, defendant's solicitors herein, consenting, ordered, adjudged and decreed as follows :

That Letters Patent of the United States, No. 249,896, granted and issued on the 14th day of June, 1881, to Thomas A. Edison for an Improvement in Electric Lamps ; and Letters Patent of the United States No. 353,783, granted and issued on the 7th day of December, 1886, to the Edison Electric Light Company, are good and valid in law.

That Thomas A. Edison was the first and original inventor and discoverer of each of the said improvements as described and claimed in each of said letters patents and that the complainant Edison Electric Light Company is the sole and exclusive owner of each of said letters patents aforesaid, and that the complainant Edison General Electric Company is the sole and exclusive licensee manufacturer under said letters patents.

That the said Bryan-Marsh Company, defendant herein, has infringed upon each of said letters patents, and upon the exclusive rights of the complainants under the same, by manufacturing, using and selling incandescent electric lamps embodying and containing the inventions and improvements set forth in each of said letters patents and recited in the claims thereof.

And it being agreed by the parties that reference to a Master be waived, and that the profits and damages to be recovered by the complainants of the defendant herein be assessed at the sum of one dollar, it is further ordered, adjudged and decreed that the complainants recover of the defendant the sum of one dollar as damages and profits for said infringement and that execution issue therefor.

And it is also further ordered, adjudged and decreed that a perpetual injunction be issued in this suit against the said defendant, restraining it and its attorneys, solicitors, servants, agents and workmen, and each of them, from directly or indirectly making or causing to be made, or using or causing to be used, or vending to others to be used, any incandescent electric lamps made in accordance with or embodying or containing any of the inventions or improvements described and claimed in said letters patents or either of them, or from in any way infringing said letters patents or either of them of the rights of the complainants under the same.

E. H. LACOMBE,
U. S. Circuit Judge.

New York, November 29, 1895.

It is hereby agreed that the above decree shall be entered in the above entitled cause.

DYER & DRISCOLL,
Complainants' Solicitors.
COCHRAN & TOMLINSON,
Defendant's Solicitors.

The specifications and drawings of the patents in suit are here presented :

THOMAS A. EDISON, OF MENLO PARK, NEW JERSEY

INCANDESCENT ELECTRIC LAMP.

Specification forming part of Letters Patent No. 242,896, dated June 14, 1881.

Application filed December 15, 1880. (No model.)

To all whom it may concern :

Be it known that I, Thomas A. Edison, of Menlo Park, in the County of Middlesex and State of New Jersey, have invented a new and useful Improvement in Incandescent Electric Lamps (Case No. 269) ; and I do hereby declare that the following is a full and exact description of the same, reference being had to the accompanying drawings, and to the letters of reference marked thereon.

In the use of that class of incandescent electric lamps in which the carbon consists of a filament bent into a horseshoe shape and having its ends secured in clamps, difficulty is sometimes experienced from the carbon bending and falling over.

The object of my invention is to obviate this difficulty by constructing a device which will hold the carbon in an upright position ; and to this end my invention consists in employing a supporter made of glass or other insulating material, having a support at its upper end, by which the carbon loop is held erect.

In the accompanying drawings, Figures 1, 2, and 3 are front views of different forms of my device ; Fig. 4, an edge view of one form, and Fig. 5 a view of a carbon which may be used.

1 2 are the wires passing through the glass N and terminating in the clamps *b*. In each of these clamps is inserted one end of the carbon A A, which is bent into a loop. The glass N is continued upward in the form of a long stem, B, as in Figs. 2 and 3, which has attached to its end a suitable device for holding the carbon erect.

Fig. 1.

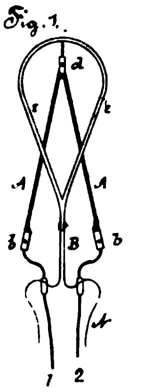

Fig. 2.

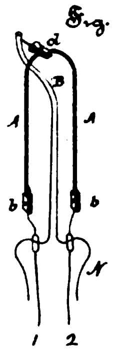

Fig. 5.

Fig. 4.

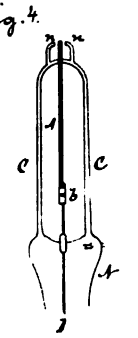

Fig. 3.

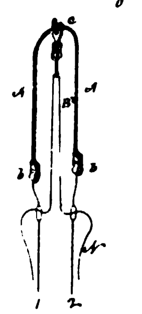


In the form shown in Fig. 2 a projection extends out laterally from near the top of the stem B, and carries the clamp *d*, made of platinum or other suitable metal not easily affected by the current, in which is inserted the loop of the carbon A A at the point *a*. With such construction it is preferable to construct the carbon with an enlarged part, as shown at *a*, Fig. 5, in order to give a larger bearing-surface for the clamp *d*.

In Fig. 3 the stem B is shorter and is not bent, and the projection extends directly upward from its top. The clamp at the end of this projection holds the Y-shaped piece *c*, preferably of platinum, between the prongs o which the carbon loop passes, and is thus kept from falling over sidewise.

In the form shown in Fig. 4 a loop of glass, C C, extends upward, being placed at right angles with the carbon loop. The projections *n n*, extending upward from the glass loop, are arranged one on each side of the carbon, and so keep it from bending or falling. In Fig. 1 the carbon is differently formed, extending up from the clamps in straight lines meeting at *d*. The stem of glass B extends up between the carbons a short distance, and then branches off into a loop, *e e*, which passes around above the point of junction of the carbons, and directly above this point a glass stem projects downward, having on its end the clamp *a*, which holds the ends of the carbons.

What I claim is—

1. The combination, with the incandescing loop of an electric lamp, of a support arranged to maintain the carbon loop in its normal position.

2. The supporting-neck in which the wires leading to the loop are sealed, provided with an arm for maintaining the loop in its normal position, substantially as set forth.

This specification signed and witnessed this 3d day of December, 1880.

THOS. A. EDISON.

Witnesses :
H. W. SEELY,
S. D. MOTT.

THOMAS A. EDISON, OF MENLO PARK, NEW JERSEY, ASSIGNOR TO THE EDISON ELECTRIC LIGHT COMPANY, OF NEW YORK, N. Y.

INCANDESCENT ELECTRIC LAMP.

Specification forming part of Letters Patent No. 353,783, dated December 7, 1886.

Application filed November 9, 1882. Serial No. 76,381. (No model.)

To all whom it may concern :

Be it known that I, Thomas A. Edison, of Menlo Park, in the County of Middlesex and State of New Jersey, have invented a new and useful Improvement in Incandescing Electric Lamps (Case No. 512) of which the following is a specification.

In the manufacture of incandescing electric lamps it may be sometimes desired to construct a lamp of exceedingly high resistance. A convenient way of doing this is to take a considerable length of very fine fiber—such as flax, ramie, or similar vegetable material—and coil or loop it into a compact shape and then carbonize it, the material forming upon carbonization an exceedingly fine flexible filament of carbon. The coils or loops are of course at some distance apart. In a lamp of this kind it is desirable that intermediate supports should be provided for the coils or loops between the leading-in wires, as otherwise such coils or loops would bend and get out of shape and perhaps touch each other.

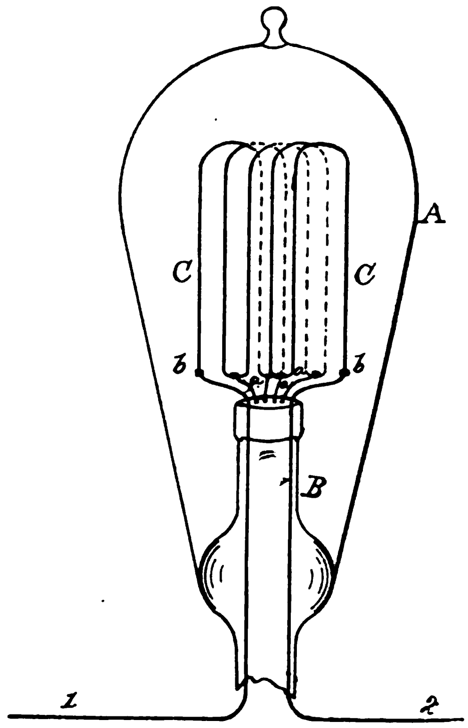
My invention therefore consists in providing intermediate supports for the coils or loops of the fine flexible carbon filament made as described.

My invention is preferably carried out by attaching to the lower portion of each coil or loop, preferably by the electro-deposition of copper, a wire the other end of which is sealed in the glass of the inner stem or wire support of the lamp.

My invention is illustrated in the accompanying drawing, wherein A is the inclosing globe of an incandescing electric lamp, and B the inner stem or wire support.

C C is the incandescing conductor, consisting of a fine filament of flexible carbon bent into a number of loops, as shown ; or the filament might be coiled into compact shape, if desired. The radiating surface and resistance of the filament are so proportioned that the entire filament will give the candle-power desired. Each loop has electroplated to it a wire, *a*, the other end of which is sealed in the glass of stem B, whereby all the loops are supported. The ends *b* and *b* of the filament are electroplated or otherwise attached to the leading-in wires 1 2.

Instead of the arrangement shown, a number of loops or coils of flexible carbon may be electroplated or otherwise attached together in series, intermediate supports being provided, as before.



What I claim is—

1. The coiled or looped carbon filament of an incandescent electric lamp provided with intermediate supports for the coils or loops, substantially as set forth.

2. In an incandescent electric lamp, the combination, with the coiled or looped carbon filament, of a number of wires attached to the coils or loops and all sealed in the glass stem of the lamp, substantially as set forth.

3. In an incandescing electric lamp, the long and fine flexible carbon filament made in one piece, in combination with leading-in wires connected to the ends of the same, and intermediate supports, substantially as set forth.

This specification signed and witnessed this 3d day of November, 1882.

THOMAS A. EDISON.

EDWARD H. PYATT.

Telephone Litigation.

Stanley S. Stout, attorney for the Western Telephone Construction Company, Chicago, has brought suit against the Strowger Automatic Telephone Exchange of Illinois for $25,000 damages growing out of the failure of the switches installed at Chariton, Ia., La Grange, Ill., and other places.

THE INEFFICIENCY OF THE DIRECT METHODS OF CONVERTING HEAT INTO ELECTRICAL ENERGY.[*]—II.

BY LEON LE PONTOIS.

THE PYRO-MAGNETIC GENERATOR MOTOR.

It has long been known that iron remains magnetic at red heat, above which point it somewhat suddenly ceases to be magnetic and remains at a higher temperature non-magnetic. This important fact was discovered by that pioneer in electricity and magnetism, Dr. Gilbert. He first showed that a loadstone and a piece of iron equally lost their power of affecting the magnetic needle when heated very hot, and noticed that the magnetic property returned to the iron after it had cooled a little, but that the natural magnetism of the permanent magnet is altogether destroyed. Faraday was the first to discover that there was a critical temperature at which steel magnets lose their magnetism, this temperature varying according to the hardness and structure of steel. This phenomenon has been investigated by quite a number of distinguished electricians, such as Prof. Elihu Thomson, Dr. Hopkinson, and experiments made on different samples of iron, steel and nickel have established the most remarkable fact that at a temperature of 770° C. the magnetization of iron is 11,000 times as great as that of substances which we are accustomed to consider as non-magnetic. A; a temperature of 785° iron is practically non-magnetic, that is, presents an extremely high magnetic reluctance. It seems that the effect of rise of temperature is to diminish the maximum magnetization of which the body is capable—slowly at first, rapidly at the end. It also very greatly diminishes the coercive force and increases the facility with which the body is magnetized. The critical temperature at which magnetism disappears changes rapidly with the composition of steel. For very soft charcoal iron wire the critical temperature is as high as 880° C.; for hard Whitworth steel it is 690° C. This curious property of iron has been utilized in the construction of apparatus for converting, directly, heat into electricity or motive power.

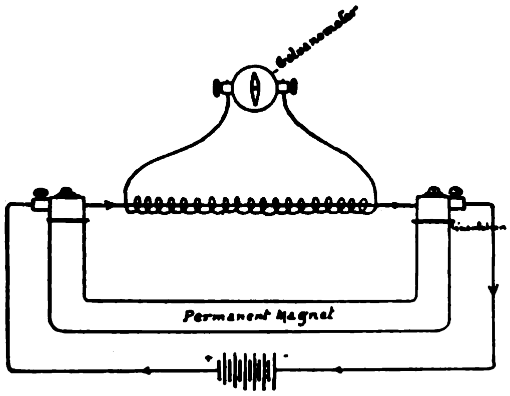

FIG. 3.—GORE'S THERMO-MAGNETIC INDUCTOR.

As far back as 1868 Dr. Gore brought before the Royal Society of London an apparatus in which the principle of the thermo-magnetic generator is fully exemplified. A straight wire of soft iron was placed in the field of a permanent magnet so as to better the magnetic circuit. The wire was fastened by its extremities to two binding posts connected to a circuit including a contact breaker and a battery. A coil of fine wire connected to a galvanometer was wound on a thin glass tube surrounding the iron wire. On sending the current of the battery through the iron wire the latter was heated, its magnetic reluctance increased thereby, and the number of lines of force threading through the coil being altered, current was induced in the coil as shown by the deflection of the galvanometer needle.

On disconnecting the battery, thereby cooling the iron wire, a reversed direction of induced current was produced. No induced current occurred by heating the iron wire if the magnet was absent, nor was any induced current obtained if the magnet was present and wire of copper or german-silver were heated to redness instead of iron wire. It is evident, therefore, that the variation in the magnetic reluctance of the iron wire was the cause of the phenomenon.

In 1879 Prof. E. J. Houston and Elihu Thomson devised a very curious thermo-magnetic motor. This motor, though devoid of practical value, is of sufficient scientific interest to warrant a description. A ring of thin steel was mounted on an axis, so as to be quite free to move, the edge of the wheel being placed opposite the poles of a magnet. The ring being placed at an equal distance from both poles, the lines of force distribute themselves symmetrically on each side of the ring, and the magnetic reluctance of the circuit is minimum under the existing conditions.

If, when the disk is heated at one of the extremities of the diameter, A A^1—B B^1, at the exttemity A, for instance, the reluctance of the heated part of the ring increases, a lateral pull is exerted on the axis, but no rotation takes place, because the resultant of the force exerted by the magnet on the disk passes by the center of the latter.

If, now, the heat is applied at some points 45 degrees apart from A or A^1 the field tends to rotate the ring about its axis in order to allow of an even distribution of the lines of force through the iron, corresponding to a minimum magnetic reluctance. If the source of heat be kept at the same place, and if the disk is thin enough to cool up rapidly, it can be readily seen that the distribution of the lines of force will be constantly modified and that permanent rotation will result of the constant tendency of the field to keep down its reluctance. By means of this little motor mechanical energy is directly obtained from heat, but its efficiency is vanishingly small, for reasons that we will show later on.

In a paper in 1887 before the American Society for the Advancement of Science, Thomas A. Edison described the principle and mode of action of his new machine for converting heat into electricity. The pyro-magnetic generator (such was the name given by Edison to his invention) excited great expectation at first, but in despite of the great inventive ability of the greatest of modern inventors, the efficiency of this machine has never, as far as I know, exceeded 2 per cent.

The pyro-magnetic generator is based on a principle quite similar to the thermo-magnetic motor of Prof. Thomson, but while the latter is a mere toy, the former is a very ingeniously designed machine from a scientific as well as from an engineering point of view. Indeed the pyro-magnetic generator could not be much improved upon—and the reasons for its efficiency do not lie in an imperfect application of the principle discovered by Gilbert, but in the fact that all apparatus based on similar principles are bound to be inefficient ipso facto.

The pyro-magnetic generator motor has many points of resemblance with the ordinary dynamo—in fact it is a dynamotor, provided with an armature looking somewhat like a squirrel cage, rotating in a magnetic field. The armature consists of eight hollow iron cores, constructed of corrugated sheet-iron covered with asbestos and wound with wire. These are held in place by two circular plates, through the center of which runs a shaft carrying at its lower extremity a semi-circular shield of fire-clay, called a guard-plate, which covers the ends of four of the armatures. The field is made of wrought-iron pole pieces, bent in a U, between the lips of which the iron cores are rotated. The shaft carries a cylinder of insulating material, having metallic contact pieces let into it on opposite sides, the line joining them being parallel to the straight edge of the guard-plate. Upon this cylinder eight springs press, each spring being connected to the end of one of the armature coils. The springs are so adjusted that each of them comes into contact with its metallic segment just as the preceding coil of the pair to which it is connected is uncovered by the rotation of the guard-plate. Upon the same shaft and above the cylinder just mentioned a pair of metallic rings are placed, insulated from the shaft, to each of which one of the metallic segments is connected. Brushes pressing upon these rings take off the current produced by the generator. The entire machine is placed upon the top of a furnace, fed by a blast, so that the products of the combustion are forced up through the interstitial cores which are not covered by the guard-plate, and raise them to a high temperature. On rotating this plate the cores are successively uncovered on the one side and covered on the other, so that continually during the motion the magnetic reluctance of four of the coils increases, while the magnetic reluctance of the other four decreases—hence the armature is constantly rotated; and the variations in the number of lines of force threading through the coils varying according to the reluctance of the cores on which they are wound, alternating currents are set up in the moving coils, and they are rectified by the commutator.

In a paper read before the Franklin Institute some years ago Dr. Carl Hering pointed out, with his well-known ability, some of the causes on account of which the efficiency of the pyro-magnetic generator is so low.

A study of the principles involved in this machine shows us that there is a practical limit to the E. M. F that can be induced with a given field magnet. The E. M. F. is, as you know, proportional to two factors—the magnetic induction, or the number of lines of force which is theoretically unlimited, since the field magnets can be made of any size, and the speed at which the armature cuts the lines of force.

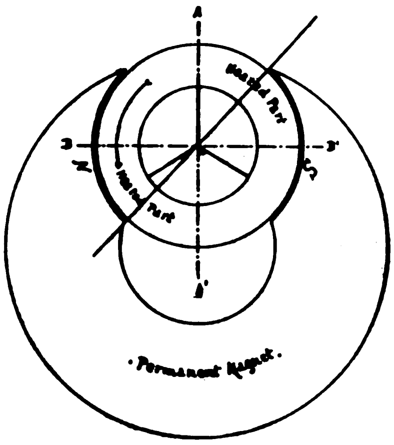

FIG. 4.—HOUSTON'S THERMO-MAGNETIC MOTOR.

In the case of an ordinary dynamo, this speed can be as high as wanted, but in the case of the pyro-magnetic generator this factor depends essentially on the speed at which the magnetic reluctance of the iron can be modified by heat. Edison has found by experiment that 120 heatings per minute are about the fastest rate at which these changes can take place. This means that the lines of force of the field can be cut 240 times per minute, while in a dynamo running at the moderate speed of 1,200 revolutions they are cut 2,400 times per minute. This means that for a given weight of wire on the armature the field magnet should be ten times as powerful as in an ordinary dynamo. Hence the pyro-magnetic generator must be quite large in comparison with the ordinary dynamo.

Another bad feature of this machine is that the iron cores which are to be heated and cooled so rapidly must be made of very thin metal, and as they have to be brought to a high temperature in order to modify their reluctance, it is evident that a rapid oxidation and disintegration of the metal takes place which would seriously affect the life of these parts of the machine. Both of these features are not, however, an insurmountable obstacle, and affect but very little the efficiency of the machine.

As in all heat engines, the efficiency of this motor depends upon the temperature difference in working

---

[*] Paper read before the Engineers' Society of Western Pennsylvania.

—the rate of temperature variation—and upon the proximity to the points of maximum effect.

No advantage will be gained by raising the temperature of the heated portion above the point at which its magnetic reluctance is maximum, or practically zero, nor on the other hand would it be advantageous to cool the part between the screens below the point where its magnetic reluctance is practically a minimum. In order to get the best results the difference of temperature working should not be greater than 15 degrees Centigrade.

The efficiency of the pyro-magnetic generator motor should not be lower than the efficiency of an ordinary dynamo motor, if we consider it as an electric generator—but the reason for its inefficiency as a whole must be attributed to the fact that it is nothing else than an ordinary dynamo directly driven by a very inefficient heat engine. If we consider that the specific heat of magnetized iron is greater than that of unmagnetized. it follows that the difference is evidently that which may be converted into motive power.

We have seen that the best range of working is between the temperatures of 785 degrees Centigrade and 770 degrees—if we apply to the case the formula of Carnot $\frac{To-T_1}{To}$ equals efficiency, we obtain 1.9 per cent. as *theoretical efficiency*. If it were possible to limit the heating and cooling in such a way that the greater part of the heat actually consumed could be the difference in *specific heats*, then the efficiency of the machine might be increased, but this is obviously impossible.

As early as 1885 Berliner obtained alternating currents from a stationary coil wound upon a hollow iron core, which was part of a magnetic circuit, the heat of a furnace or a cold blast of air that was successively sent through the core causing variations in its reluctance, and thereby currents were induced in the coil. Tesla has made numerous experiments in the same field, causing small iron armatures to oscillate in front of magnets. In some cases he obtained direct rotation, but these experiments are of secondary interest, because they had already been made long before him by Gore, Thomson, Cooper, Berliner.

Tesla's thermo-magnetic generator is practically based on the same principle as Berliner's, but differs from the latter by details of construction which improve greatly the plant efficiency of the machine. Besides, the products of the combustion, after having heated the iron, are directed under a small boiler placed on the top of the apparatus, and the steam generated is sent through the tubes instead of an air blast. The use of steam as a cooling device is original, and in a certain measure effective, for it diminishes considerably the oxidation of the iron tubes, and thereby increases the life of the machine. However, the efficiency of this thermo-magnetic generator is not superior to the efficiency of the pyro-magnetic generator, because both apparatus, being based on the same principle, work between the same limits of temperature, and are ipso facto inefficient.

From the unsuccessful experiments made in this fascinating field by distinguished inventors and scientists, we may conclude that it is not very likely that electricity will ever be obtained, efficiently, from heat. By the word "electricity" I have reference to those long ether waves by means of which we manufacture light and transmit energy to great distances over wires. A time may come when the beautiful system of lighting and power transmission by means of currents of high potential and frequency devised by Nikola Tesla, will be as practical as it is efficient; then we might succeed in obtaining the considerably shorter electric waves used in that system direct from heat. This is, however, a dream of the future that may never be realized—and while we are confronted with the necessity of obtaining electricity as economically and simply as possible, it seems to me that the commercial solution most promising of success is to improve the gas engine, and harness it to the highly efficient alternating current dynamo.

WATER POWER—ITS GENERATION AND TRANSMISSION.*

BY SAMUEL WEBBER.

The engineers who have been for many years engaged in the question of water-supply for large cities have laid it down as an established fact that, by means of proper and complete storage basins, one-half the annual rainfall may be thus saved, the other half being either absorbed by vegetation or dissipated by evaporation.

This amount has been usually estimated for our Northern cities at 1,000,000 gallons per day from each square mile of drainage area, or one-half an annual rainfall of 42 inches, which is a fair average for the larger part of the United States, east of Kansas and Nebraska, rising, according to Blodgett, as high as 50 and 55 inches, in parts of the southwestern States, but a safe estimate for the area of drainages from the great Appalachian range, which is as wide an area as we propose to consider in this paper.

It will be readily seen that this annual rainfall of 42 inches amounts to nearly 732,000,000 gallons on a square mile, so that 1,000,000 gallons per day is almost exactly half of it. To secure this half, however, requires the most complete and perfect system of storage basins possible, and it is not safe to calculate on such an amount as being available for water power by any possible and economical means of storage.

It is possible, however, by practicable means of storage, to secure about one-third of the rainfall, and as water for power purposes is usually measured in cubic feet per minute, or per second, instead of gallons, we will now adopt this mode of computation.

An annual rainfall of 42 inches is equal to 267,409 cubic feet per day on a square mile, or 3.09 cubic feet per second, and if we take one-third of this, or 1 cubic foot per second, from each square mile of drainage area, we arrive at the supply which can usually, by the aid of storage, be relied upon.

The late James B. Francis, for many years the engineer of the Locks and Canals Company at Lowell, on the Merrimac River, once gave me the following data as the result of many years' observation of the flow of the Merrimac River, which, however, does not take in the few days of "spring freshets," when the snow is going off from the mountains, and the river so high and swollen as to be practically unmeasurable:

	Cu. ft. per min. per sq. mile.
Spring flow	90
"June flow," about the average	55
Minimum flow in Aug. and Sept	30

The minimum flow has, however, been less than that once or twice in recent years, as, in 1881, it was only 26.7 cubic feet per square mile drainage area, or .445 cubic feet per second. This diminution has been due to the destruction of the forests around the head-waters of the river, and such forest destruction must be borne in mind by every engineer as a probability when making estimates on a projected water-power.

It will be seen that this 30 cubic feet per minute, or 0.50 cubic feet per second, the minimum flow, is but one-sixth of the rainfall, and in order to secure the one-third, which I have considered as available, a sufficient "pondage" must be secured above the dam, at the proposed water-power, or in some other convenient location, to store the night flow, if the water is used in the daytime, or vice versa, so as to get a double quantity during working hours without too much diminution of the working head.

This is practically accomplished at Lowell, where the observations on the water-power of the Merrimac River have been longer continued and are more complete than any others of which I am aware, by the pond made by the dam. This pond is 18 miles long, with an average width of 500 feet. The drainage area of the Merrimac, above Lowell, is 4,093 square miles, and if we take the minimum flow as 0.50 cubic feet per second, we have a total flow of 2,000 cubic feet per second.

Col. James Francis, who has succeeded his father as agent and engineer of the Locks and Canals Company, informs me that, with 3 feet of "flashboards" on the dam, giving a fall of 34 feet, they can store in this pond, at a depth of 1.50 feet, 71,874.000 cubic feet of water, which, if drawn down the 18 inches in 10 hours, would give them 6,165 horsepower, which, added to the daily flow of the same 2,000 cubic feet, would give at low water a total of 12,330 horse-power. The original estimate of the power available at Lowell was 10,000 horse-power on 30 feet fall; but by raising the dam above, and removing obstructions below, this power has been increased. as shown.

The net effect of the present turbines in Lowell is here taken at 80 per cent. There are, however, in place at Lowell turbines enough to utilize 20,000 horse-power, for which water is furnished for a portion of the year, but which have to be supplemented by steam-engines, to supply the deficiency, when the water is reduced to a minimum flow, as above quoted.

In addition to this, the mills at Lowell, Lawrence and Manchester, N. H., have also derived great benefit from the use of the water stored in Lakes Winnepesaukee and Winnesquam, in New Hampshire, where the outlets were deepened, and weirs and gates put in below, enabling the water-power companies to draw down these lakes in the summer to a depth of 12 feet below the full height in spring, or 6 feet below their normal summer level. The area of these lakes above the Lake Company's dam is 71.8 square miles; and Col. Francis gives me the following data of the amount of water furnished by them for several consecutive years:

Year.	Horse-power furnished for 3 months.	Depth drawn at lake.
1878	659	4.20 feet.
1879	809	5.16 "
1880	1,299	8.28 "
1881	1,600	10.20 "
1882	1,506	9.60 "
1883	282	1.80 "
1884	1,845	11.76 "
1885	69	0.44 "
1886	1,067	6.80 "
1887	0	0 "

The variation in seasons is seen to be considerable.

Leaving this branch of the subject, with the repetition of the statement that, by storage, one-third of the rainfall can be relied on for power for day or night, I now take the question of turbines.

The modern turbine is the evolution of ages from two distinct types, one of which delivers the water in a tangential direction to radial arms or vanes, projecting from a central shaft, without confining it in any way; the other conveyed it in a closed tube to hollow radial arms, through which it passed, and, leaving them in a tangential direction, gave, by the reaction pressure, a rotary motion to the whole apparatus.

We can trace both systems back to such remote antiquity that it is useless to attempt to find the origin; and as the principal developments of both have been made within the present century, we need go back no farther. As we shall devote much less time to the second of these types, or the "outward discharge," we shall consider it first, and simply refer to the well-known "Barker Mill," or the "Whitelaw & Sterret," sometimes called the "Archimedian" wheel, as the first modern type of this style.

In 1827, Mr. Fourneyron applied this principle of the outward discharge from a pipe to a wheel with curved buckets placed outside of the apertures of discharge, so as to receive the water in a direction perpendicular to the first and inner element of the curve, which appears to be practically cycloidal, and which, revolving from the action of the water, finally discharged it at its outer element at the circumference, with its force exhausted; i. e., the best results obtained from this form of turbine were shown by Mr. Francis, in his "Hydraulic Experiments," to be when the circumference of the wheel *at the point* of discharge had reached the velocity due to the water under the fall, or 62 per cent. of the *theoretical* velocity due the head, from the action of gravity, this being the result of what is known as the "contracted vein." At this velocity of the wheel the water falls away dead into the pit, to take a new direction due to the fall in the "tail-race."

---

* Abstract of Paper read before the American Society of Mechanical Engineers, December, 1895.

In the Fourneyron turbine, the tube, or feeder, which supplied the water, was closed at the bottom by a concave cone surrounding the wheel shaft, which passed up through it in a pipe, and was not exposed to the water. This cone was surrounded by a number of guide plates, curved like the buckets, but in the opposite direction, and fastened to the cone; and these delivered the water to the buckets in the proper tangential direction. This first turbine of 1827 was followed by another, in 1834, of 7 or 8 horse-power, which worked at times under a head of only 9 inches.

Then came several others, under higher heads, of 63, 79, 126, and 144 feet respectively, giving from 71 to 87 per cent. net effect of the power of the water.

In 1837 came the celebrated one of St. Blasien, 20 inches in diameter, weighing 105 pounds, under a head of 72 feet, and this was followed by one of 13 inches diameter, under a head of 354 feet. The width of this wheel across the buckets was only 0.225 inches, and it made 2,200 to 2,300 revolutions per minute. It is said to have driven 8,000 cotton spindles, with the other accessory machinery, which would require from 100 to 120 horse-power, and to have given from 80 to 85 per cent. net effect. The apertures of the buckets were so small, however, that the water was all filtered before entering the feeder, to avoid clogging them.

The success of these wheels led to their introduction to this country by the late Uriah A. Boyden, who placed the first ones in Lowell, in 1844, and these were rapidly followed by others, until their use became almost general in the large manufacturing towns of New England. Those built under Mr. Boyden's instructions gave as high as 80 per cent. net effect, and he claimed to have got 88 per cent. at the Atlantic Mills in Lawrence.

Their manufacture was taken up by a number of builders, but they did not all obtain such high results, and owing to the multitude of buckets, with the small apertures, they were liable to become choked by chips and leaves and other floating obstructions, not to speak of fish—for at Fall River the first turbines are said to have been stopped by eels, on their annual migrations to the sea, from Watuppa Lake.

The net effect at partial gate was also very poor, owing to cutting off the water by the sharp edge of a cylinder, as shown by the writer in a paper presented to this Society, and included in Volume III of the Transactions.*

Attempts have been made to obviate this by introducing diaphragms in the buckets, so that only a part of the bucket is affected by this sharp cut-off, and this is shown in the Swiss turbines now being introduced at Niagara Falls, but this division only reduces the dimensions of the apertures, and renders them more liable to choke from obstructions. This form of wheel, as built by Mr. Boyden, was also enormously expensive, and they have generally given place, as they wore out, in forty or more years' use, to the "inward and downward flow" turbine, which we shall now proceed to trace. This, as we said in the outset, comes from the old "flutter-wheel" of radial vanes inserted in a central shaft, which supported a grindstone, or "millstone," on top of it, and which is one of the earliest traces of mechanical application of force to be found in history. India, Egypt, Syria and Europe all appear to have used this primitive water-wheel to grind their corn. It is impossible to determine when the modifications of this form began, but, in 1804, a patent signed by Thomas Jefferson was granted to Benjamin Tyler, of Lebanon, N. H., for "an improvement in water-wheels" in which he claimed "hooping the wheel with iron hoops," and specified the proper angle at which to set the buckets, "made of winding timber."

Similar improvements were early made in the mountainous districts of France, where metal buckets, curved either vertically or horizontally, were bolted to a central shaft, and were known either as "*rouets a cuve*," or "*rouets volants*," and in common parlance with us were known as "tub-wheels." The water was applied to all these wheels "tangentially," by a trunk or spout which delivered it at the circumference. Next, this trunk was made in the form of an Archimedian screw, which applied the water equally all around the wheel, the top being closed, and the discharge at the bottom. A wheel of this sort was patented by John Tyler, grandson of "Benjamin," above referred to, in 1855. I have no record of the dates of the European improvements in this direction, but, as early as 1843, Elwood Morris, of Philaldelphia, experimented with and reported on what is generally known as the "Jonval turbine," in which the radial buckets are curved vertically, and the water directed to them by a set of stationary guides, curved in the opposite direction, and fixed to the interior of the tube or feeder which supplied the water. This form of wheel has also been known as the "Koechlin" and as the "Froment" turbine; the name of "Jonval," I believe, only applies properly to the "draught tube" arrangement, which was patented in this country by Zebulon and Amasa Parker, of Licking, O., in 1840.

These wheels were sometimes, in cases of low heads, set directly in the bottom of the wooden flume or forebay, in other cases supplied by an iron feeder pipe. The Froment turbine, which the writer saw in the London "Crystal Palace" of 1851 was of the former character, and the gates were a series of "plungers," which fitted down between the guides. J. P. Collins, of Norwich, Conn., has adopted this form of gate; others, as Mr. Geyelin, of Philadelphia, have used what is known as the register gate, a term derived from the common hot-air heating apparatus. Still another form has been a sliding telescopic tube, outside, which throttles the water after leaving the wheel, and seems to the writer objectionable, but has been applied to the turbines at Niagara.

This class of wheels, known as the "downward flow," has proved effective and economical, and they are particularly suited for large and constant powers at low heads, but are deficient at partial gate, if the gate is of the register or telescope pattern. The writer has obtained 84 per cent. net effect with two "Geyelin" turbines, in different localities, when at "full gate."

We must now turn to a different form of wheel, the "inward flow," patented in 1838 by Samuel B. Howd, of Geneva, N. Y. In this the action of the Fourneyron wheel is reversed, and the converging guides, which were straight, were placed outside the wheel, which had curved buckets, revolving inside the guides, and was, in fact, only one form of the old "tub wheel." Mr. Francis has stated (see "Hydraulic Experiments") that a similar wheel was suggested by General Poncelet, in 1826.

In the Howd wheel, the regulating gates were placed outside the guides or "chutes." The buckets were cast iron, fastened by bolts to wooded top and base plates, and the discharge was central.

In 1849 Mr. Francis took this matter up, and built, for the Boott Mills in Lowell, an inward discharge wheel, in which he employed the carefully designed curves of the "Boyden" wheel, and which gave excellent results, nearly equal to those of the outward discharge.

This type of inward discharge gave much greater facilities for operating the gates, and was followed by a number of variations, notably the "American Turbine," of Stout, Mills & Temple, of Dayton, O., in which the form of gate adopted gave much better results than were obtained when partially closed, by the cylinder between the guides and buckets, which Mr. Francis copied from Mr. Boyden. This wheel at the Boott Mills lasted until 1875, when it was replaced by a "Swain wheel." In 1855, A. M. Swain, a mechanic who had been employed at the Lowell machine-shop in the construction of the Boyden and Francis wheels, conceived an idea which produced the prototype and exemplar of all the modern American turbines. He combined the inward and downward flow wheels, curving the buckets both laterally and vertically, and discharging the water mainly downward, where a reversed curve in the base on which the wheel rested threw it outward again, so that the path of the water was a semicircle. He adopted a form of gate which, instead of cutting off the water abruptly, closed the orifice by which it entered the wheel, by lifting the lower side of the tube, so as to contract the passage, which still retained a rounded aperture. The result produced by this was marvellous; instead of 30 per cent. effect at part gate, or half water, he got 66 per cent., and 83.4 per cent. at full gate, when the wheel was finally perfected in 1875.

The Swain wheel had, however, given excellent result as far back as 1862, and from that date down to about 1878 the number of turbines was legion, in all sorts of variations of curve of bucket and form of gate, but all containing the same general features of inward and downward discharge. Of these, the Leffel wheel combined both forms of bucket, separated by a diaphragm in the same wheel, and has given excellent effects.

The general result of this change from the Fourneyron type, as first introduced, has been to furnish the public with turbines of equal power, in one-half the space and at one-fifth the cost, being single castings of iron or bronze, instead of built up of many parts. The general line of evolution, beginning with the Swain wheel, has been that of fewer and deeper buckets, with wider openings to avoid obstruction by floating matter, and in some of the wheels like the Hercules the narrow openings of the "chutes" have been retained, preventing such matter from entering the wheel itself.

This latter wheel brings us to the date of 1876, when what is known as the "new departure" wheels were introduced. The first of these was the "Hercules," designed by John B. McCormick, of Brookville, Pa., who brought it to the Holyoke testing flume to be tried, and the results were such that the Holyoke Machine Company at once entered into its manufacture.

The principal feature of this wheel was a much smaller diameter, with longer buckets and deeper openings, for any proposed amount of power.

This wheel was at once followed by the "Victor," made by Stilwell & Bierce, of Dayton, O., on the same general lines, but differing in form of bucket and gate; and many of the older wheels have been since changed or improved in the same direction, and the following table will show the difference in quantity of water used and power obtained by a number of wheels of nearly the same diameter, under the same head of 26 feet, beginning with the "Boyden Fourneyron," and ending with the "Victor":

	Inches Diameter.	Cubic feet Water per sec.	Horse Power.
Boyden Fourneyron	36	22.95	55
Risdon	36	35.45	89
Risdon "L. C."	36	48.27	121
Risdon "D. C."	36	80	199
Leffel, Standard	35	40.45	96
Leffel, Special	35	60	148
Tyler	36	40.7	95.8
Swain	36	58.2	140
Hunt, "Swain bucket"	36	48.8	121
Hunt, New Style	36	96	239.74
Leffel, "Samson"	35	109.1	264
"Hercules"	36	107.6	253.5
Victor	35	108.8	266

This enormous difference in productive effect in wheels of the same diameter shows the great economy of the later type of turbines, particularly as all the wheels above named have a *proved* efficiency of 80 per cent., and some of them have given more; such as 87 per cent. for the Risdon, tested by Mr. Edward

---

* Efficiency of Turbines as Affected by Form of Gate. Vol. III, p. 84, No. 61.

Sawyer, of Boston, at Crompton, R. I., and by the writer at the Centennial; 87 per cent. for the Hercules, tested by Professor Thurston; 84 per cent. for the Collins, by the same authority; 84 per cent. nearly for the Swain, by Mr. Francis; 84 per cent. for the Geyelin and the Hunt, tested by the writer, and 88 per cent. for a 15-inch "Victor," by the same, but this was so small a wheel that the test cannot be depended on. Later tests of large wheels at the Holyoke flume give over 80 per cent., and to these may be added the "Success" of E. Morgan Smith, York, Pa., and the "Humphrey," Keene, N. H., and the wheel of Gates Curtis of Ogdensburg, N. Y., also the "New American" of the Dayton Globe Iron Works, Dayton, O. Here all questions of selection must be governed by other reasons than that of mere efficiency, as all the above seventeen wheels have been proved to give 80 per cent. or over net effect. Nearly all these wheels have been adapted to horizontal shafts, for high heads, where the belt pulleys can be kept out of water, and so far as they have been tested show no difference in economy from that given on vertical shafts. A "Hunt" wheel, tested by Mr. Francis, *in situ*, in a mill at Lowell, only varied a fraction of 1 per cent. on a horizontal shaft from the result obtained on a vertical one by Mr. Herschel at the testing flume in Holyoke.

While the writer has expressed a preference for the "downward flow" wheel when the head was low and bevel gears necessary, he would prefer the new type of small diameter wheels for horizontal shafts under high heads, as they give a greater initial velocity to the shafting, the friction of bevel gears is avoided, and if set in pairs, to thrust against each other, step friction, which is very destructive in muddy streams, is also done away with.

The first instance in which turbines were placed in pairs in this manner, in the writer's memory, was in 1875, when A. M. Swain installed a pair at Ticonderoga, N. Y., which were very successful. Since then all the prominent wheel builders have adopted it, and it has become very general in all cases where the head was sufficient to keep the pulleys out of water. It also gives the advantage of easy and immediate access to the wheel for examination or repairs, by a manhole in the case, if the head-gates to the feeders are closed. The writer installed a pair of Risdon turbines for the Nashua Manufacturing Company in this way some time since, and, asking the man who had charge of them, after two years' use, "if anything had been required to be done to them?" he answered, "Nothing but to oil the stuffing-boxes, and open and shut the gates." Like all other water-wheels, the turbine is somewhat slow in answering to regulation under a variable load, as it takes more time to open and close the gates than it does to trip the "cut-off" in a Corliss engine, but the "Snow" and "Schofield" governors are very effective, and can be recommended.

Among the other points mentioned in the schedule is the testing of turbines "*in situ*," and in regard to this the writer would say that a few points need careful attention. The friction pulley should be flanged, to keep the brake in place, and amply strong, and a safe size for it is to allow 1 square foot of surface motion per second for every 3,000 foot-pounds per second lifted; this gives a pressure of a little over 20 pounds per square inch. The brake should be of timber, fitted to the pulley, one-third the circumference on each edge, leaving two openings of one-sixth circumference for lubrication. The best lubricant is strong, thick soapsuds, about the consistency of molasses, and this should be constantly fed from a can or cans in a stream the size of a quill, and may be diluted in use by a jet of cold water from a hose or pipe, played in through the openings, to cool the pulley. The brake lever is most convenient if made the radius of either a 33-foot or a 66-foot circle, that is, practically, 5 feet 3 inches or 10 feet 6 inches long from center of shaft to point of attachment of weight. The whole apparatus should be perfectly balanced at rest before commencing operations.

When we come to the matter of cost, we find it to vary much in different localities, according to the expense of development. The cost at Lowell, when the first "mill powers" were opened, had been only $40 per horse-power for dam, land and canals. This was increased $50 per horse-power by the new canal, which gave more certain head and enabled the mills to use the surplus water which ran to waste part of the year, and the total cost has probably been $100 per horse-power, to which another $100 is to be added for the expensive Boyden wheels and massive masonry pits. At Augusta, Ga., the canals, nine miles long, cost the city, which leases the power, $90 per horse-power. At Columbia, S. C., for five miles of canals the cost to the city has been $72 per horse-power.

In many cases of smaller enterprises it has been less than $50 per horse-power, and the total cost, including wheels and pits, less than $100, and we will now give the data of the cost of water-power as developed within recent years at three different points, showing the outlay, and a fair allowance for interest and running expenses.

The first instance we shall give is that of the Concord Water Power Company, on the Merrimac River, at Concord, N. H. Here the power developed is at a minimum 3,300 horse-power, on an average 5,000 horse-power, from a fall of 22 feet. The wheels are "Rodney Hunt" turbines, set in pairs on horizontal shafts of 400 horse-power each. The cost has been as follows:

700 acres Land, and Flowage Rights	$20,000
Dam and Abutments	141,015
Canal, 60 feet wide	27,363
Head Gates	16,675
Waste Weir	5,220
Making an investment for water of	$210,273

or $63.72 for the minimum amount of power, or $42.05 for the average amount of power. To this is to be added pits and foundations put in for 2,000 horse-power, $15,000, or $7.50 per horse-power; wheels put in for 1,600 horse-power, $12,225, or $7.66 per horse-power; making a total for the minimum flow of water of $78.88 per horse-power, and for the average flow of $57.75 per horse-power.

Now, if we base our calculation of cost on the minimum flow, and allow interest 5 per cent., sinking fund 2½ per cent., repairs 1½ per cent., taxes, etc., 1 per cent., we get a total annual *cost* of 10 per cent., or $7.89 per horse-power, to which add oil and attendance, 75 cents, making $8.64.

As this power is to be transmitted, in part at least, to Concord by electricity, the cost of such transmission, on which I do not assume to be authority, will have to be added to this. If, on the other hand, it is to be partially used near at hand, it is safe to say that the cost of transmission by shafts and belts would not increase it to over $10 per horse-power.

If we assume the average flow of 5,000 horse-power the cost of the power at the wheels would be only $5.72, but we should then require the additional expense of a steam plant, and its operation, to produce the 1,700 horse-power deficiency at low water.

We will now take a large Southern mill, the John P. King, at Augusta, Ga. Here the water is purchased of the city at a rental of $5 per annum per gross horse-power.

The wheels are 3 Geyelin turbines, on vertical shafts with bevel gears, estimated at 1,835.5 gross horse-power. These wheels, by my own test *in situ*, netted 84 per cent. Calling the average 80 per cent., it gives 1,468 net horse-power. This cost of plant was for wheelpits, 42 feet deep, in rock, head race, 200 by 40, tail race, 800 feet to river, about $25,000, and the wheels and jackshaft cost the same, or $50,000 in all. This, for 1,468 net horse-power, is $34.20 per horse-power, or, at 10 per cent., $3.42; water rent, $5.50 on 1,835.5 gross horse-power, equal, net, $6.88; attendance and oil, 75 cents; making a total cost of $11.05.

The next case is also a Southern one, that of the Columbia Mills, at Columbia, S. C. Here the water is also leased at a rental of $5 per horse-power. For quantities less than 500 horse-power, the charge is $7. The fall is 27 feet, and the power is furnished by Victor turbines, on horizontal shafts, and is transmitted by electricity to the mills.

Quicksands made the wheelpits very expensive, by the quantity of concrete masonry required. so that for all expenses of pits, races, power-house, etc., we have $55,000 for 2,000 horse-power. The wheels cost $20,000 more, so that we have a total expenditure of $75,000 for 2,000 horse-power, or $37.50 per horse-power. This, at 10 per cent., as before, gives $3.75 per horse-power; water rent, $5 per horse-power; attendance and oil, 75 cents; making a cost at wheels of $9.50 per horse-power.

As the water rent paid in the last two cases covers interest and depreciation, while the cities which furnish the water also obtain their own supply for other purposes, it will be seen that it covers the cost, and that the estimate of Mr. Samuel Batchelder, fifty years ago, that the cost of water-power in Lowell, including land, was under $15 per annum per horse-power, was substantially correct, and will cover the cost of water-power with modern turbines, under fair circumstances, to-day, with plenty of room to spare for heating.

The Storage Battery.*

A DISCUSSION OF ITS APPLICATIONS BY THE MEMBERS OF THE A. I. E. E.

PRACTICAL EXPERIENCE WITH STORAGE BATTERIES IN CENTRAL STATIONS.

BY C. L. EDGAR.

Mr. Edgar's paper dealt mainly with the experience of the Edison Electric Illuminating Company of Boston in the use of storage battery as a central station adjunct. In his discussion of the subject he made the following classification of the uses to which the storage battery may be applied in central station work: To carry the peak of the load at maximum hours; to carry the entire load at minimum hours; to act as an equalizer or reservoir, and for the equipment of annex stations.

In carrying the peak of the load, Mr. Edgar summarized the experience of his company as follows:

"We have found that if we divide our maximum load of the year into two parts the upper half exists only for about two hours under ordinary circumstances, and four hours under exceptional circumstances for the five winter months. Computing the kilowatts in these two halves, we find that the lower half contains 90 per cent. of the K. W. hours manufactured, whereas the upper half contains only about 10 per cent. This would prove the position taken by some engineers that if an extremely large station was to be constructed it would probably pay to equip it with two types of apparatus—50 per cent. to be of the best economy and most expensive class known to the art. This to do the 90 per cent. of the work. The other 50 per cent. to consist of crude, cheap, uneconomic but reliable apparatus, to do the 10 per cent of the work. The saving in interest on the lesser investment in the second class would be much greater than the extra cost of running this half, due to its poor economy.

"In our particular case we find ourselves in precisely this position. Our company installed in years past about 4,000 H. P. of high speed, belted, bipolar apparatus, reliable, but of poor economy. Some three years ago it changed to the other extreme and commenced to equip with the highest priced and most economical apparatus to be found in the market, and to-day there is about 4,000 H. P. of this apparatus in use.

"Ninety per cent. of our kilowatts have been manufactured by the vertical, triple expansion, multipolar units, and yet the total capacity of this apparatus is not over 50 per cent. of our maximum output for the winter.

---

*Abstracts of communications read at the 101st Meeting of the American Institute of Electrical Engineers, New York and Chicago, November 20, 1895.

"The application of the storage battery to these conditions is obvious. What we need, and what all companies under generally like circumstances need, is a piece of apparatus capable of doing two hours' work per day which is cheap, and which has fair economy. If storage batteries could be used under no other circumstances than these, it is, perhaps, somewhat doubtful whether it would pay to install them, but yet I am inclined to think that considering their first cost and the efficiency which we can obtain from them, it could be fairly proved that it would pay to use them rather than what I have designated as the cheap type of apparatus.

"At the time our first battery was purchased, our standard unit was 650 H. P. We therefore called for a battery of 650 H. P. capacity for two hours. We eventually, under stress of circumstances, reduced this to one and a half hours and found that it cost considerably less than a first-class steam plant.

"As all apparatus has to be installed for the express purpose of taking care of the maximum load, it seemed to us very clear that if we could save in our first investment by installing storage batteries which cost less than a steam plant, we were going to be able to do a given amount of work with a less amount of capital by this means than by any other. We thus decided to install a battery to take care of the peak even if we obtained no other advantage from it.

"I think that the nature of the load curve in America is against the use of batteries to carry the entire load at minimum hours to anything like the same extent as abroad. With us there is only about six hours of minimum load, whereas, owing to the lack of motor business in Europe, the minimum there extends some days from midnight until three o'clock in the afternoon.

"Our generating department has gone through some exhaustive experiments, running first the engines for 24 hours a day, charging the battery at minimum load, and then turning around the next week and shutting down the steam plant for the six hours from midnight until six o'clock in the morning, and depending entirely upon the battery. The general conclusion seems to have been arrived at that the former is the cheaper method. Admitting this, the indirect advantages of the former, by which the battery is charged during the night, and can be used during the following day, are very much greater than if the battery were discharged during the night, as it could not be completely charged again until the middle of the afternoon of the following day. I do not consider our conclusions final, as the local conditions might materially change the result.

"It is the use of the battery as an equalizer or a reservoir with which we have been particularly pleased. In order to understand, it is perhaps desirable to explain the needs which a modern station has for apparatus of this kind. Years ago a distribution company was equipped with one station, furnishing electricity through a system of feeders, supplied from one 'bus bar. All this is changed. To-day the modern station manufactures electricity in various places, transfers it from one station to the other at will, sends it out through a system of distribution at three or four pressures supplied from 'bus bars of varying potential. At the minimum hours of the day the electricity is manufactured by one set of dynamos, part of it being delivered to the 'bus bar in the station in which the dynamos are located, the remainder being sent out over tie lines to various annex stations and delivered there to the local 'bus bar.

"The fluctuations of load on central and annex stations are everyday occurrences, and if we were not equipped with a battery, it would be almost an hourly question as to what it was necessary to do next, whether to start dynamos, stop them, change boosters or any other of the innumerable combinations which might be made. In a very large degree the battery answers all these questions or at least makes them unimportant. It makes it possible to determine beforehand what the regular day's work of the steam plant is to be, to decide how many and at what time boilers are to be put in service, when engines are to be started or stopped, and in general to operate the plant to its best economy, knowing that daily or hourly inequalities in the load, or uncertainties caused by the weather will be taken care of by the battery. It is kept in multiple with one or the other or all 'buses at all times. It is supposed, for many hours of the day, to be standing idle with the ampere meter at zero, but it may, without a moment's warning, be called upon to either give or take anywhere from one to 3,000 amperes on a side. It is possible in this way theoretically to keep every engine which is running loaded up to its maximum economy at all times. Having satisfied ourselves in the beginning that with a given amount of capital we could do more work with the battery than without it, we by actual practice came to the conclusion that we could by the same means do this same amount of work more cheaply. When we remember that we installed the battery for the express purpose of taking care of the maximum load, we are, of course, particularly pleased at the very great use we can make of it for this purpose of equalization, and yet, in addition to this we have made enough tests to prove to our own satisfaction that we do not lose anything in fuel economy by this particular use of the battery. The watts lost by the inefficiency of the battery are made up more than fourfold by the better economy of the steam plant. We have taken typical winter days and figured out exactly the cost of running our system with the battery and without, and have proved that the actual coal consumed with the battery is a material amount less than without it. If, in addition to the fuel, we take into account the very great saving in the labor, the added reliability and the better service given, we will see that these uses of the battery are even greater than those for which it was originally installed.

"I do not think it is possible to overestimate the advantages of storage batteries for the purpose of giving regularity and reliability to a system of distribution. With very sudden fluctuations in the load, which are continually taking place, it is almost impossible with dynamos alone to regulate the 'bus pressure so quickly that the pressure throughout the system remains constant. The uses of the battery very much simplify this problem. Very many times where in the past it was necessary to change the magnetism of the fields of dynamos, it is now necessary to do absolutely nothing, the battery acting as a reservoir, giving out quantities of current without any apparent change in pressure for the time being.

"This question of regularity is very closely connected with the one of reliability. To those of us who are identified with central station work, there is a great sense of security when we realize that whatever may happen to the steam plant we have sufficient battery to carry us over a few minutes of disorder. In our particular case, we have at the present time sufficient battery to run 60,000 lamps for five, ten or fifteen minutes, depending upon how great is the emergency. This advantage of the battery may not appeal to an outsider. I do not think they can realize the intense nervous strain to which all connected with the successful detail operation of the station are subjected. If a battery and a steam plant were on a par in all other respects than this, I should personally feel very much inclined to install it for this reason alone."

In the Boston station there has yet been no occasion to make use of the battery in the equipment of annex stations. Of this use Mr. Edgar said:

"When we realize that it makes very little difference to which end of a tie line a storage battery is connected, we can see at once the special advantage which this type of apparatus gives us. If of such value that it will pay to install them, it is a matter more or less immaterial whether they are installed at the main station or at an annex station connected to the main station by tie lines. The fixed charges of running a battery room are very small as compared with those of a steam station, and there would not be any very material increase of fixed expense between one large battery located in a central point and a half dozen small ones distributed throughout the city.

"Storage batteries, therefore, lend themselves particularly to the location of a 'central' station at some convenient point upon the water front, and the building up of small centers of distribution scattered throughout the city, consisting of storage batteries with or without a steam adjunct and connected together possibly, but certainly each one connected to the central station.

"Our company has used the first battery 20 months, and one of double its capacity for six months, entirely too short a time to come to any conclusion about the depreciation, but it has given us ample time to satisfy ourselves as to the economic value. It is sufficient for me to say that if a need should arise to-morrow for additional capacity, either at our main station, at either of the annexes or in any new part of the city, within reasonable distance of our center of distribution, we should consider the question along the lines which I have just indicated. We should eliminate entirely from the discussion the question which has distracted the public mind for so many years and decide it entirely upon its merits, placing the battery side by side and on an equality with other modern and improved apparatus."

Gold Medals for the Westinghouse Company.

(From the Atlanta Constitution.)

The Westinghouse Electric and Manufacturing Company of Pittsburg, Pa., has come off with flying colors at the Exposition. This well-known and extensive concern was awarded two gold medals by the Exposition board of highest awards. One medal was awarded for photographs, plans and descriptions of the two-phase generating plant recently installed at Niagara Falls. The other medal was awarded for induction motors and dynamos illustrating the two-phase alternating system for the transmission of power.

These awards were a recognition of the company's high standing in the electrical world and of the precedence it has always had as manufacturers of electrical supplies.

The full significance of this victory by the Westinghouse Company will be understood when it is stated that only five gold medals were awarded in the Electrical Building, and of these five, two were given to the Westinghouse Company.

The exhibit of this company has attracted considerable attention and much favorable comment ever since the opening of the Exposition, and the awards of the board will meet with universal indorsement so far as the decision made in favor of the Westinghouse Company is concerned.

Electricity, especially in the way of lighting, has made generous sanitary contributions which deserve appreciation. Dr. Saunders, the medical officer of the London Board of Health, says the electric light in general use has accomplished a great deal in making the employees of commercial and manufacturing establishments healthier. Faces that were pale and wan from work in gas-lighted basements, stores and shops are much improved since the introduction of electricity. The heat from the gas jets and poor ventilation are responsible for much sickness. It is also shown that in the same city the electric light has lessened crime. Darkness breeds wickedness and light dispels it.

A real Indian chief emerges this month in the field of periodical literature. Simon Po-ka-gon, of the Pottawattomies, contributes to the *Review of Reviews* a brief statement of his views about the Indian Territory "Squaw Men" and the question of Indian reservations. His article is sententious and direct and withal not lacking in the picturesque phraseology of the Indian's language.

LEGAL NOTES.

Vice Chancellor Reed has granted an injunction restraining the Union Traction Company of Newark, N. J., from collecting any debts or transferring any stock, and will appoint a receiver to take charge of the company's assets. The company was organized only a year ago, and capitalized at $1,500,000, but it now goes into the hands of a receiver for a debt of $166.66 due Luther Shafer, of Rutherford, for office rent.

At the instance of the General Electric Company of New York, an execution has been issued against the Carbondale Traction Company, of Carbondale, Pa., for $2,760.24, and another for the same amount against the Lackawanna Valley Rapid Transit Company.

The Circuit Court has ordered a sale in equity of the Buchanan Electric Light and Power Company of Buchanan, Mich. The sale is fixed for January 17, 1896. The water power included in the property is derived from a dam 400 feet across the St. Joseph River, with a fall of 12 feet, giving a power estimated from 2,500 to 4,000 horse power. The company was organized and incorporated April 14, 1893, and capitalized at $100,000, but lack of financial support, together with unprecedented hard times has forced them to give up the fight, after spending, according to the statement of the company's officers, the sum of $125 000. Among the franchises is one for lighting the village for ten years at $50 per lamp, also one for the erection of a dam five miles lower down the St. Joseph River.

Wm. L. Dayton, ex-Minister to The Hague, has been appointed receiver of the Asbury Park and Belmar Street Railway Company. The road runs from the Ocean Grove gates to Shark River, Belmar, N. J.

The Elgin (Ill.) Electric Illuminating Company has been notified by the General Electric Company that it is infringing on the latter's patent by using the bridge circuit around a single dynamo and transferring switch.

The Mutual Electric Light and Power Company of Brainard, Ill., has made an assignment to Randall W. Burns. The assets of the company are about $25.000; liabilities a like amount.

An important suit is now on trial in the Supreme Judicial Court of Massachusetts. The style of the action is Mary B. Howe et al. vs. the West End Street Railway, and the issue involves the question of electrolysis, damages for which the plaintiffs have received no restitution. It is held that while the act of 1887 gives the railroad a right to operate by the electric system, there was no provision in that act allowing the abutters to receive compensation for injury to their property. The suit will in fact determine the constitutionality of this law.

PERSONAL.

Among our out of town visitors this week have been Messrs. C. J. Mayer and F. A. Estep, of the Nuttall Company, Allegheny, Pa.; E. L. Babcock, Falls Rivet Machine Company, Cuyahoga Falls, O.; John Dick, Phœnix Iron Works, Meadville, Pa.; J E. Keelyn, President Western Telephone Construction Company, Chicago; J. H. Rhotehamel, President Columbia Incandescent Lamp Company, St. Louis, and Morgan Brooks, President Electrical Engineering Company, Minneapolis, Minn. Messrs. Dick and Brooks were attendants at the annual meeting of the American Society of Mechanical Engineers.

New York Electrical Society.

A meeting of the New York Electrical Society will be held at the "Marble Church," 29th street and Fifth avenue, New York City, on Thursday, December 12, at 8 P. M., when Mr. George G. Wacker, the well-known organ builder, will deliver a lecture accompanied by instrumental illustrations on the subject of "Electricity in Organ Playing." Mr. Wacker will be assisted by Mr. R. T. Percy, the organist of the church, who will play the illustrative selections and also one or two pieces, including the overture from "William Tell," which will demonstrate the perfection attained, through the aid of electricity, in performing on separate and distant instruments from one keyboard.

OBITUARY.

Thomas McCoubray.

Thomas McCoubray, who died December 5, 1895, was born in the District of Columbia, May 20, 1847, of Scotch-Irish stock on both sides. His early life was spent in Baltimore, Md. He graduated from Baltimore City College. He became a prominent member of the Free and Accepted Masons; was five times elected Master of St. John's Lodge, twice elected High Priest of St. John's Chapter, and Eminent Commander of Baltimore Commandery No. 2, Knights Templar. He served as Grand Inspector for one term; was one of the organizers and the first Grand Potentate of Boumi Temple, A. A. O. N. M. S.; was a thirty-third degree Mason of the A. A. Scottish Rite, having held offices in each of the bodies, and was secretary of the board of relief.

At one time Mr. McCoubray was secretary of the National Electric Light Association, and subsequently held several positions of trust in the commercial department of electrical enterprises. Of late he gave his attention to invention and developed the auto-telephone system.

Association of American Manufacturers.

The annual meeting and banquet of the above Association was held at the Grand Central Palace, this city, on the evening of December 5. The object of this Association is to increase the international trade of American manufacturers in various lines.

The officers of the Association are as follows: G. Martin Brill, president, Philadelphia; F. E. Myers, Vice-President, Ashland, Ohio; Lucius S. Bigelow, Secretary, Harrisburg, Pa.; J. Horace McFarland, Treasurer, Harrisburg, Pa. Executive Committee: D. R. Morse, Chairman, New York; H. W. Anderson, Harrisburg, Pa.; E. J. Pearson, Hartford, Conn.; F. P. Williams, Brooklyn, N. Y.; F. H. Cutler, Buffalo, N. Y.; H. J. Heinz, Pittsburg, Pa.; J. A. Jeffrey, Columbus, Ohio.

St. Louis Electrical Men Eat and—Talk.

The fourth annual banquet of the St. Louis Electrical Club was held on the 7th inst., Capt. Robert McCulloch acting as both chairman and toastmaster. Col. Ed. Meier, C. E. Randall, Walter Flower, Capt. O. J. Schultz, Prof. F. Nipher, of Washington University, and H. A. Wagner spoke on various topics allied to electrical interests and on the recent assistance given by electricity to the other sciences.

The Next N. E. L. A. Convention.

The Executive Committee of the National Electric Light Association has formally selected Tuesday, Wednesday and Thursday, May 5, 6 and 7, 1896, as the time and the New York Industrial Building, described in ELECTRICITY last week, as the place for holding the next or Nineteenth Convention.

Second Annual Ball.

The associated employees of the firm of Zimdars & Hunt. 127 Fifth avenue, New York. will hold their second annual ball in the Central Opera House, on 67th street. on Monday evening, December 16. The ball room has been appropriately decorated for the occasion with special electrical designs.

Henry Electrical Club.

Prof. Francis B. Crocker will deliver a lecture on "Methods of Driving Dynamos" at the Henry Electrical Club, American Institute Rooms, on Friday evening, December 13.

Thomas M. Kenna, of New Haven, Conn., has devised a mechanism to obviate the jolting of electric cars and pounding of the rail joints. The device is a simple one and consists of four small auxiliary wheels two on each side of the car and located between the wheels proper. With them a car will run smoothly over all deflections in the rails and passengers will escape the jar occasioned when the wheels meet the ends of rails.

GENERAL NEWS.

What is Going On in the Electrical World.

Arcadia, Wis.—The Milling Company has decided to put in an electric plant to light the streets and business places.

Baraboo, Wis.—The flouring mill of J. G. Heaton was destroyed by fire recently; an electric light plant in the mill was ruined.

Hull, Mass.—At a special town meeting held a few days ago, the sum of $5,000 was voted for additions to the electric light plant.

Key West, Fla.—Work on the electric railway here will soon begin. An expenditure of $125,000 will be made in building and equipping the road.

Holyoke, Mass.—The Hadley Thread Company has decided to run a part of its plant by electricity, and the contract has been awarded for the plant.

Bath, N. Y.—The Albany, Greenbush and Bath Railway Company has applied to the trustees for a franchise to run its cars in the streets of this village.

Birmingham, Mich.—Work has begun here on the Oakland Electric Railway, the promoters of which propose to run their line from Detroit to Pontiac.

Sistersville, W. Va.—The city council has granted a franchise for the establishment of an electric light plant in this city to McGhie & Morse of East Liverpool, Ohio.

Sleepy Eye, Minn.—This place has confirmed the appropriateness of its name by voting against the bond scheme to raise $5,000 to pay for an electric light plant.

Lancaster, O.—H. B. Peters, receiver of the Lancaster street railroad, says the entire franchise will soon be sold to a new company who will improve and operate the road.

Boston, Mass.—The agitation in favor of municipal lighting seems to be increasing in this city, and Brookline and other towns in this neighborhood are discussing the subject.

Crowley, La.—An electric plant has recently been put in operation at the Crowley rice mills and gives great satisfaction. The mills are extensive, having a daily capacity of 3,000 barrels.

Batavia, N. Y—The aldermen have voted to give A. B. Wilgus until August 1, 1896, in which to build and have in operation at least three miles of his electric street railway in Batavia.

Purcell, I. T.—The Purcell Electric Supply Company turned on electric lights in this town on the 3d inst. Purcell is the first place in the Chickasaw Nation to adopt electric lighting.

Vancouver, B. C.—The city council has let a ten-year contract for arc street lighting to the Western Electric Lighting, Heat & Power Company, a branch of the Western Electric Company of Chicago.

Pittsburg, Pa.—The force of workmen at the Westinghouse electric works has been increased, the foundry department having been put on double turn, necessitating the employment of 150 additional men.

Spokane, Wash.—It is probable that the council will authorize the purchase of an electric lighting plant for the power house, head gates and dam at the new waterworks; the board has recommended that course.

Bainbridge, O.—It is understood here that a New York syndicate have had an inspection made of the route of the proposed electric road between this place and Chillicothe, and that the inspector made a favorable report.

Knoxville, Tenn.—The sale of the Park Street line of the Knoxville Electric Street Railway has been confirmed by Judge Clark at Chattanooga to J. E. Chamberlain, the sale having been assigned to him by W. G. McAdoo.

Fairbury, Wis.—The Fairbury Electric Light & Power Company has sold its franchise and plant to the Water Works Company and the two plants will hereafter be under one management. A new power house will be built.

Independence, Mo.—C. W. Baker, a practical electrician of Kansas City, has purchased the electric light plant here and will operate it under the name of the Western Lighting Company. He will furnish the city with lights.

Staten Island, N. Y.—The fight between the Staten Island Electric Railroad Company and the Midland Company over a franchise to run electric cars in certain streets in New Brighton has terminated in the granting of a franchise to the first named company.

Port Jefferson, L. I., N. Y.—The Port Jefferson Electric Light Company has been organized to furnish electric light for this village with a capital stock of $7.500 fully subscribed. The company expects to have the plant in operation within ninety days.

Niagara Falls.—A report is current here that New York capitalists are having surveys made for a new electric road from Echota to Sanborn, thence to North Tonawanda, and from there to Buffalo. The road is intended to carry freight as well as passengers.

Cleveland, O.—December 10 has been set for the opening for traffic of the Cleveland & Elyria electric railroad. Mayor M. H. Levagood, of Elyria, has extended an invitation to the officials of the road and to others to attend a banquet and celebration to commemorate the event.

Waukesha, Wis.—Application has been made to the village board by the Milwaukee & Waukesha Electric Railway Company for a franchise to operate an electric street car system in this village. Should the franchise be granted, work will begin on the road early in the spring.

Berkley, Va.—A corps of engineers has been at work in Princess Anne county in the last few days surveying a route for an electric railroad from Berkley to deep water on the Currituck Sound, and it is reported that the laying of the track will be commenced by the first of the year.

Buffalo, N. Y.—The Niagara Falls Power Company has accepted the amended franchise proffered by the city authorities, the 14th clause, providing for the annulment of the grant on 30 days' notice of failure in carrying out its provisions having been changed to 90 days' notice.

Hoboken, N. J.—An ordinance granting the Jersey City, Hoboken and Rutherford Electric Railway Company a franchise to run cars through First and other streets to the New York ferry has passed its first reading in council. The company offers a lump sum of $20,000 for the franchise.

Columbus, O.—As the present contract for lighting the streets expires in February, bids will be advertised for at once. Specifications made by Director Bliss have already been published. The contract will be for ten years, all night lighting, and underground wires in the business portion of the city.

Topeka, Kan.—Representatives of a Chicago electrical company have been here figuring on the cost of new boilers and dynamos for the city electric light plant, the intention being to extend electric lighting to the suburbs covered by the contract with the Vapor Light Company which expires on the 14th inst.

Watertown, N. Y.—Col. J. A. Lawyer of this city has been appointed receiver of the Watertown & Brownville Railroad Company, on the application of the Central Trust Company of New York as trustee of a $75,000 mortgage against the railroad company. The latter operated all the electric lines in this city and Brownville.

Medford, Mass.—A special commission will investigate the cost, economy of maintenance, advantages and disadvantages of a municipal electric plant, and is to report to the city council all the facts and data secured. The commission is to have the right to employ electrical and engineering experts as they shall deem requisite.

Newark, N. J.—The executive committee of the directors of the Newark Electric Light & Power Company have recommended to the directors that a general reduction be made in arc lighting of about 5 per cent., in incandescent lighting of about 7 per cent., and in the cost of electrically generated power of about 10 per cent.

Brooklyn, N. Y.—The new electric road proposed from the end of the Kings County Elevated to Jamaica and Far Rockaway is expected to be completed by June. The contracts have been awarded and iron has been ordered from Pittsburg. It is proposed to extend the line to Hempstead next year, and thence on to Babylon.

Bloomfield, N. J.—The street-lighting committee of the Bloomfield township committee have advertised for proposals for lighting the streets of the town with arc and incandescent lights. The bids will be opened at the regular meeting of the township committee on the evening of December 16.

Los Angeles, Cal.—A local paper says that one of the finest and most perfectly managed lines of suburban railway in the United States is that of the Pasadena and Pacific line, which connects Los Angeles with adjacent suburban cities and towns. On the west the line reaches the coast, while to the east and north the fertile valley of San Gabriel is traversed.

Norristown, Pa.—Several capitalists are said to be back of the scheme to build a trolley road from Phœnixville to Pottstown, via Royersford and Spring City, and an inspection has lately been made of the route. The prospects are that the road will be built and eventually extended from Phœnixville to Valley Forge and on to this borough.

Ottawa, Ill.—The Ottawa Electric Street Railway, including all real and personal property, has been sold by the receiver, in obedience to an order of the United States Circuit Court at Chicago, to the General Electric Company, the only bidder, for the nominal sum of $7,500. The company, unless the local capitalists take the plant off its hands, will tear it up and remove it from the city.

Warren, O.—It is reported that plans are being made for an electric railway from Warren or Leavittsburg to Ravenna, which would give the Mahoning Valley lines connections with the A. B. C. road, which runs from Akron to Cleveland. If this is done, as it is believed it will be, Cleveland and Pittsburg will soon be joined by electricity, as lines are already arranged for between Youngstown and Beaver Falls.

Roanoke, Va.—This city may be considered one of the most enterprising municipalities in the South. It is lighted by gas and arc and incandescent electric lights. It has fourteen miles of street railway now operated by electricity. It is connected with Salem, seven miles, by electric cars, and Vinton, four mills, by electric cars. The Roanoke river affords first class power for manufacturing purposes.

Long Island City, N. Y.—The announcement is made that a syndicate of Philadelphia capitalists has acquired the entire street railway system and electric lighting plant of this city. There are about sixty miles of trolley road in operation and additional mileage will shortly be completed; besides which the system's electric lighting privileges are quite extensive. It is understood that the deal represented a transaction of nearly $2,000,000.

Vevay, Ind.—The city council has made a contract with Alex. S. Schulman, of Cincinnati, for putting in an electric light plant which is to consist of 40 street arc lights, each of 1,200 candle power, and 800 incandescent lights, each of 16 candle power. The contract requires the plant to be in running order by February 15, 1896, at which time the present contract for the lighting of the streets expires.

Owosso, Mich.—The official name of the new corporation running the motor line between Owosso and Corunna, which is being changed into an electric line, will be the Owosso & Corunna Traction Company. President J. D. H. Ralph states that the change was made to give the business world notice that the new company has no connection with the former company, which has passed into the hands of a receiver.

Westport, Conn.—The Westport & Saugatuck Street Railroad Company has equipped part of its four miles of road with a third rail electric system. An important feature of the new system is that the feed rail only becomes charged as the car passes over it. The feed, or third rail, is located in the center of the other two rails and a circuit to the motor is obtained by means of a trolley underneath the car.

Fort Wayne, Ind.—Within a week the Fort Wayne Electric Corporation has made several important shipments of machinery, among them a 1,000-light alternator to Yoakum, Tex.; 800-light dynamo to Lexington, O.; 125-light Wood arc dynamo to the Manchester Electric Light Company, Manchester, N. H.; a dynamo and fixtures to the University of Wisconsin at Madison, Wis.; a steamboat plant to the Marmet Company at Cincinnati, and a 600-light incandescent to Thompsonville, Mich.

Chicago, Ill.—The General Electric Railway Company of this city has received propositions from the Siemens & Halske Company of America and from the General Electric Company of Schenectady for equipping an underground trolley system in the South Side streets, but holds these propositions in reserve until a trial is made of the Brandenburg system, which the company has definitely decided to use.

Shreveport, La.—Proposals for lighting the city by electricity for a term of five or ten years will be received until December 12. From 50 to 70 arc lights will be required. The contractor must agree to erect and operate within the limits of the city an electric plant sufficient for such public lighting, and also such machinery, appliances and power as may be needed to furnish lighting and power for residential and commercial uses.

Schenectady, N. Y.—The rumors of a threatened strike at the General Electric works seem to have a substantial foundation. At a meeting held lately by the workmen an organization was formed taking in every man who was not already a member of some union, and much dissatisfaction was evinced among those in attendance because of the low wages paid by the company. Some of the workmen say that they have been cut in their wages so that they can hardly earn a living.

Chattanooga, Tenn.—Considerable interest is being manifested as to the sale on December 23 of the Chattanooga electric street railway, because of the uncertainty as to who will control the valuable property after that date. It is learned that a move is on foot among the local people who are concerned in the road to purchase it when sold and make some extensive improvements in the service. One of the contemplated improvements is the extension of the Harrison avenue line.

Fresno, Cal.—The "Exposition" speaks in glowing terms of the approaching completion and opening of the new power line. It says: "On February, 1896, will begin the calendar of a new life for our fair city. Then will disappear the mists of uncertainty and the fair, smiling Goddess of Progress will beckon our people onward into the sunshine of a glorious future. Such will be the transition inaugurated by the transmission of electric power from the San Joaquin river, thirty-three miles distant, to the city, for on that date the first current will be sent from the company's powerhouse to the substation in Fresno, and thence over the network of wires which will then be strung through the city."

Montreal, Can.—Work has been started upon the Napierville Junction Railway, an electric system which is chartered to carry freight and passengers and will run from St. Remi to Stottsville, through the parishes of St. Michel, St. Edward, St. Phillippe, St. Jacques, Douglassburg and Napierville, connecting with the Grand Trunk Railway at Stottsville. The Dominion Government has granted a bonus of $3,200 per mile for the twenty-two miles of the line, while the following municipalities have voted money to assist the enterprise: Napierville, $10,000; St. Edward, $2,500, and St. Remi, $2,000. Hon. J. G. Laviolette, of this city, is president of the company.

New York.—One of the witnesses who appeared before the Assembly Committee on Railroads in this city last week was George J. Gould, president of the Manhattan Elevated Railroad Company, whose knowledge of the financial and practical operation of railroads in general gave interest to the investigation. Among other things Mr. Gould said he considered an elevated road equipped with electricity the best road for rapid transit in a city. —One of the handsomest electrical displays lately added to the attractions of the big dry goods stores in Sixth avenue is that at O'Neill's, where the tops of the towers at both ends of the building are encircled with brilliant zones of electric lights, and over the main entrance of the store the National flag is electrically represented as if waving in the breeze, the undulatory effect being produced by an ingenious transition of light and shadow.

Alexandria, Va.—The Washington, Alexandria and Mt. Vernon Electric Railway Company has awarded the contract for the building of the new cars to the J. G. Brill Company of Philadelphia. The new cars are to be forty feet in length and handsomely fitted up. The seats will be wider and all the conveniences of the steam railway car will be found in them. They are all to be equipped with motors that will give them a guaranteed speed of forty miles an hour, so that they will be able to make the run between the two cities in about fifteen minutes, including stops. A car equipped with one of these motors, is now in the shops of the company in Alexandria, and when tested made a speed of forty-one miles per hour.

St. Louis, Mo.—The "Republic" says: "Within a week the Board of Public Improvements will be ready to submit its ordinance providing for putting electric wires underground. This ordinance is being prepared not on any resolution of the Municipal Assembly, but in compliance with the suggestions given by Mayor Walbridge in his recent message. The ordinance will, as far as practicable, follow the plan outlined by his Honor to have all the wire-using companies of the city join in constructing one general subway in which each company will have separate ducts for their respective wires, the companies to contribute pro rata, according to the space used, for the expense of construction, but the city to have entire supervision of the subway."

Kansas City, Mo.—The Metropolitan Street Railway Company is now perfecting plans for the erection of a mammoth electric power station near Riverview, from which power will be furnished for running all the lines of the company west of Main street, with the exception of the Twelfth and Ninth streets cable lines. The extensive plans of the company contemplate the changing of the motive power of the Fifth street line, and of all the cable lines in Kansas City, Kan., from cable to electricity, and running the whole system, comprising over thirty miles of street railway, from this one immense power house.—A deed from Herman Brumback, special master, conveying to the Metropolitan Street Railway Company the rolling stock, right of way and entire belongings of the Kansas City & Independence Rapid Transit Railway Company, has been filed with the recorder of deeds. The deed is the final transfer of the property, which was sold by order of court on October 19 to satisfy mortgages held by the Central Trust Company of New York. The consideration named in the deed was $600,000.

Baltimore, Md.—A blanket mortgage of $6,000,000 has been placed on the Columbia and Maryland Railway Company to secure the issue of 6,000 bonds of a par value of $1,000 each. The mortgage was placed with the Central Trust Company of New York by Thomas M. Lanahan, the president, and R. Stanley Carswell, the secretary of the railway between Baltimore and Washington which is to be operated by electricity.—The Diamond Ice Company will shortly put into operation at its artificial ice works an apparatus with which to cut ice into cakes by electricity, instead of by steam as at present. It will save labor, reduce waste and make a cleaner cut than the steam saw now in use. The electric saw consists of a simple looking iron bar, backed with asbestos. One of the great advantages of it is the fact that it will not require the constant presence of two men while making its way through the thick and heavy pieces of ice. It is self-operating.

TELEPHONE AND TELEGRAPH.

C. L. Mosley has been granted a telephone franchise in Bedford City, Va.

A telephone company is being organized at Griffin, Ga., on the co-operative plan.

The Southern Bell Company has reduced rates at Mobile, Ala., to $20 and $12 per year.

The Moosehead Lake Telegraph Company will erect a telegraph line from Ashland to Oakland, Me.

W. H. Nixon, general manager of the Nixon Telephone Company, is endeavoring to establish a local exchange at Westerly, R. I.

The ordinance granting rights to the Drawbaugh Telephone Company in Philadelphia has been referred to the city solicitor.

The ordinance granting rights to the Pennsylvania Standard Telephone Company in Philadelphia has been referred to a sub-committee.

The Georgetown, S. C., Telegraph Company has rejected the proposition of Frederick Boon, of New York, to again lease its line for two years.

The projectors of the Rossland Electric Light and Power Company, Rossland, B. C., intend to establish a telegraph line between Northport and Rossland.

Morgan T. James has secured necessary franchise rights from the city council of Youngstown, O., for the construction of his proposed independent telephone exchange.

The Central New York Telephone Company has completed the extension of its long-distance line from Utica to Watertown. The line is 91 miles long and cost upwards of $40,000.

The business men of Medina, N. Y., have organized a co-operative telephone company to supply service at $1 per month, after the first payment of $40 is made to enter the company.

The East Jersey Telephone Company is constructing a branch line in New Brunswick, N. J., to connect with the long-distance line of the New York and New Jersey Telephone & Telegraph Company.

An agreement has been made between the local telephone companies of Merrill and Wausau, Wis., to build a toll line to connect the several cities and towns of the Wisconsin valley at an early date, and thus make them independent of the toll line of the Wisconsin Telephone Company.

The Canadian Pacific Telegraph Company has completed direct connection from Winnipeg to Minneapolis, St. Paul, Duluth, West Superior and all points south. This is the last link completing the comprehensive system of direct telegraphic communication from Central and Northern Canada to all parts of the world.

The Delmarvia Telephone Company, recently organized at Wilmington, Del., has asked for a franchise. The officers of the company are: Joseph L. Carpenter, Jr., president; J. Augustus McCaulley, secretary and treasurer; J. H. Hoffecker, Jr., counsel; Lindley C. Kent, Francis E. Gallagher and Dr. Willard Springer, directors.

The Union Telephone Company of Lake Odessa, Mich., has been absorbed by the Coo.perative Telephone Company. The new company has been organized with a capital stock of $50,000. The line of the company connects with Lansing, where it has over 500 patrons, and is now being extended to Mason. It is the intention of the management to push through to Detroit and Grand Rapids. The officers of the company are: President, Wilson Elliott; vice-president, F. B. Nims; secretary, E. F. Colwell; treasurer, W. J. Percival; general manager, George A. Weed; auditor, J. J. Ross.

New Companies Incorporated.

A charter has been granted to the Harmony Grove and Athens Telephone Company of Harmony Grove, Ga.

The Mutual Telephone Company, Bloomfield, Ill. Capital stock, $1,500. Incorporators: Deane N. Funk, E. D. Funk, Jacob Funk, B. F. Funk.

The Ellsworth and Kanopolis Telephone Company, Ellsworth, Kan. Capital stock, $200. Directors: John S. Judson and C. E. Jennings, of Kanopolis; G. A. Collett, G. L. Levitt and C. W. Flanders, of Ellsworth.

The Kalamazoo Telephone Company, Kalamazoo, Mich. Capital stock, $30,000. The directors are as follows: Charles H. McGurrin, William A. Doyle, Henry F. Hodgman, Charles A. Peck and J. B. Balch.

Articles of incorporation for the Automatic Telephone Company, with a capital of $100,000, to begin business with $500, in New York City, have been filed at Albany. The directors are: Henry M. Whitney, Silas B. Dutcher and James P. Pierce, of Brooklyn; Geo. M. Hard, Ernst Thalman, R. T. Wilson, Jr., and W. E. Chase, of New York City; J. W. Hinkley, of Poughkeepsie, and J. G. Dorrance, of Nyack.

COMMERCIAL PARAGRAPHS.

The Bryan-Marsh Company closed an order this week for 200,000 lamps, which, it is claimed, breaks the record.

The Beacon lamp having grown so much in favor among Canadian users, the Beacon Lamp Company has found it necessary to establish an agency at Montreal. The Royal Electric Company has been commissioned sole agents for the Canadian Provinces.

Gardam & Burchett, mechanicians and electricians, have established an office at 58 Ann street, New York. They will develop inventors' crude ideas, prepare estimates, etc., and manufacture tools and special machinery.

The increase of the Electric Storage Battery Company's business in the West has necessitated more commodious office quarters, which are now provided by a handsome suite on the fifteenth floor of the Marquette Building, Chicago. Mr. C. W. Woodward is the Chicago representative.

It "Got There" With Ease.

Once again the Lundell Motor has gained well merited distinction for its superior qualities. This time it piloted to a successful finish the electric carriage manufactured by Messrs Morris & Salom of Philadelphia, which was entered in the recent motocycle contest held in Chicago. The coveted gold medal was awarded to Messrs. Morris & Salom.

Safety, ease of control, absence of noise, vibration and heat and general excellence of design and workmanship were some of the factors which the Lundell machine had to meet, and did meet successfully.

The Interior Conduit & Insulation Company of New York, who manufacture the Lundell Motors, are again to be congratulated upon this the latest popular recognition of the merits of their machines.

Testing Westinghouse Engines.

In a pamphlet entitled "Something About Westinghouse Engines," recently issued by the Westinghouse Machine Company, an interesting description is given of the methods employed in testing engines before shipment:

"Every engine, from the five horse-power Junior to the seven hundred horse-power Compound, after being assembled, is taken to the testing room and run continuously for several days under full load and with every condition of actual service. From there it is removed to the overhauling floor and taken entirely to pieces. An examination of the piston and valve rings is then made to ascertain if they bear properly all around; the journals and wearing surfaces are inspected to make sure there is no tendency to heat or cut; and a final and exhaustive search is made for defects of any nature. When everything is known to be right the parts are reassembled, all adjustments made permanent and the engine is then ready for jacketing, painting and shipment.

"Inasmuch as the Compound Engine is more particularly the exponent of high economy, we put each individual engine of this class through a complete economy test in addition to the above described running test. All the engines on one side of the testing room are shut down, with the exception of the one under test. The exhaust is turned into the condenser, full load is applied and measured by means of a friction brake, and indicator cards are taken simultaneously.

"The first test is made without vacuum, as good performance is more difficult of attainment under this condition than with vacuum. Occasionally a second test is run under a vacuum maintained by an independent air pump. All the steam used by the engine is condensed, and drains down into the weighing tanks, where it is weighed at regular intervals. The rate per hour being obtained, it is divided by the indicated, and the brake or net horse-power, giving the economic performance in the generally accepted units of measurement. The difference between the indicated and brake horse-power determines the frictional losses in the engine. If the friction loss is excessive, or if the economic performance falls short of our standard, the cause is sought out and removed and the engine retested before it is passed."

INCORPORATIONS.

The Phœnix Electric Company, Phœnix, N. Y.--to make and supply electricity. Capital stock, $15,000. Promoters: E. B. Powell, R. S. Sloan, O. F. Gaylord, Oswego, N. Y.; S. D. Greene, Schenectady, N. Y.

The Long Island Illuminating Company—to supply light and heat in the towns of Flatlands and Jamaica, N. Y. Capital stock, $100,000. Directors: Charles M. Lockwood, of Jamaica, and R. F. Rhodes, J. H. Holmes, Jay S. Jones, and Eugene Seamann, of Brooklyn, N. Y.

The National Electric Carbon and Manufacturing Company, Portland, Me—to manufacture, buy and sell carbon machines and carbons. Capital stock, $500,000. President, William A. Holmes, of Boston, Mass.; treasurer, Charles F. Clark, of Boston, Mass.

The Atlantic City Light, Heat and Power Company, Atlantic City, N. J.—to furnish light, heat and power by means of oil, gas and electricity, etc. Capital stock, $250,000. Promoters: W. E. Findlay, New York City; James R. Merritt, Philadelphia; John M. Kelley, Camden, N. J.

The Bronson Electric Light Company, Bronson, Mich.—to manufacture and sell electricity. Capital stock, $10,000. Promoters: H. P. Mowry, J. S. Sheneman, J. F. Werner, Bronson; Wm. H. Bond, F. C. Rhenbottom, Union City, Mich.

The Upper Alton Water Works, Chicago, Ill.—to construct water works, electric light plants, electric heat, light, and power plants; manufacture and supply light, heat and power. Capital stock, $2,500. Promoters: Geo. C. Morgan, Arthur H. Morgan, Henry A. Gardner.

The Standard Electric Car and Power Company, Portland, Maine—to develop a certain invention for improvements in electrical railways and cars therefor. Capital stock, $500,000. Promoters: Lewis A. Drake, John K. Wightman, Boston, Mass.; Leon O. Dion, Natick, Mass.

The Milner Electro Gravitation Motor Company, Charleston, W. Va.—to manufacture and deal in motive power, machinery and engines of all kinds, etc. Capital stock, $500 minimum, $5,000,000 maximum. Promoters: Wm. E. Conway, Silas H. Berry, James F. Atkinson, Thos. Hanson, Brooklyn, N. Y.

The Flathead Copper Mining Company, Kalispell, Mont. —to engage in manufacturing, mining, agricultural, chemical, electrical, mercantile, commercial and milling business, and reduction of ores, etc. Capital stock, $100,000. Promoters: James A. Coram, Benton D. Hatcher, Frank R. Miles.

The South Sioux City Traction Company, South Sioux City, Neb.—to maintain and operate one or more lines of street railway. Capital stock, $50,000. Promoters: T. L. Eaton, Henry J Taylor, C. A. Benton, D. L. Plumer, E. H. Burgess.

The Central Traction Company, Sioux City, Ia.—to construct improvements in that city, electric light and power plants, street railways, etc., steam power. Capital stock, $500,000. Promoters: Howard S. Baker, C. M. Swan, Geo. P. Morris, Sioux City, Ia.

The Metropolitan Electric and Power Company, Allegan, Mich. Capital stock, $50,000. Incorporators: Frank A. Mackin, Samuel Clark, Frank E. Semon and others.

The Parry Sound Electric Light Company (Limited) at Ottawa, Can. Capital stock, $20,000.

The Woodhaven Electric Light Company, Jamaica, N. Y. Capital stock, $25,000. Directors: J. H. Smith, James Cochran, J. C. Milligan, of Brooklyn, and others.

The stockholders of the Wayne Electric Light Company of Wayne, Pa., have increased the capital stock of the company from $75,000 to $100,000.

The Elmhurst Electric Light and Power Company of Elmhurst, Ill., has certified to an increase in capital stock from $15,000 to $30,000.

The stockholders of the Pontiac and Sylvan Lake Electric Railway Company, of Pontiac, Mich., have decided to issue $10,000 in 21-year bonds to Comstock & Company, the Chicago construction contractors.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 3, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

550,683. Trolley-Wire Crossing. John C. Kinney, San Antonio, Tex. Filed April 17, 1895.

550,775. Speed-Indicator and Alarm. Franz Blumenstein and Ernest Bobsien, Mount Vernon, N. Y. Filed May 13, 1895.

ELECTRIC LIGHTS AND APPLIANCES.

550,574. Electric-Arc Lamp. Thomas E. Adams, Cleveland, Ohio. Filed March 14, 1895.

550,600. Electric-Arc Lamp. Stefan Doubrava and Josef Donat, Brunn, Austria-Hungary. Filed Feb. 2, 1895.

550,860. Electric Car-Lighting Apparatus. William Biddle, Brooklyn, N. Y. Filed Jan. 7, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

550,663. Dynamo-Electric Machine for Plating. William M. Thomas, Chicago, Ill. Filed March 25, 1893.

550,666. Dynamo-Electric Machine. Henry P. White, Kalamazoo, Mich., assignor of three-fourths to Charles D Fuller, same place. Filed Jan. 29, 1895.

550,692. Armature. Henry G. Reist, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed Aug. 31, 1895.

550,703. Commutator. Henry P. White, Kalamazoo, Mich., assignor of three-fourths to Charles D. Fuller, same place. Filed Jan. 29, 1895.

550,782. Method of Distributing Electricity to Electric-Lighting Systems. Charles M. Davis, Chicago, Ill. Filed April 14, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

550,658. Permutation-Selector. Almon B. Strowger, Chicago, Ill. Filed June 14, 1894.

550,728. Automatic Telephone-Exchange System. James G. Smith, New York, N. Y. Filed Feb. 18, 1893.

550,729. Automatic Exchange System. James G. Smith, New York, N. Y. Filed Feb. 20, 1893.

550,765. Signaling Apparatus for Telephone-Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed April 16, 1895.

MISCELLANEOUS.

550,577. Electric Switch. Christoph Bach, Jr., Milwaukee, Wis. Filed April 12, 1895.

550,638. Electrical Protective Appliance. Alfred H. McCulloch, Boston, Mass., assignor to the New England Telephone and Telegraph Company, of New York. Filed Sept. 14, 1895.

550,670. Signal-Circuit. John V. Young, Boston, Mass., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed July 8, 1893.

550,673. Cross-Over Insulator. Frank G. Beron, Waterbury, Conn., assignor of one-half to James F. Gaffney, same place. Filed Feb. 18, 1895. Renewed Oct. 4, 1895.

550,682. Voltmeter, Frank Holden, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed Aug. 31, 1895.

550,686. Electric Cigar-Lighter. James F. McLaughlin, Philadelphia, Pa. Filed April 24, 1893.

550,688. Electrotherapeutic Apparatus. Charles Palmleaf, Seattle, Wash. Filed April 1, 1895.

550,733. Electric Safety Device. Elihu Thomson, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed May 19, 1887.

550,743. Adjustable Igniter for Explosive-Engines. Thomas G. Cantrell, San Francisco, Cal. Filed April 8, 1895.

550,812. Holder for Electroplating. Elbert R. Allen, Wallingford, Conn., assignor to Simpson, Hall, Miller & Co., same place. Filed Sept. 30, 1895.

550,822. Self-Winding Electric Clock. Charles M. Crook, Chicago, Ill. Filed March 25, 1895.

550,823. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Filed May 22, 1895.

550,841. Electrical Measuring-Instrument. Herschel C Parker, Brooklyn, N. Y. Filed May 9, 1895.

550,857. Electric Time-Alarm Attachment. Max Wolff, New York, N. Y. Filed July 3, 1895.

550,866. Electric Furnace. Frederic Chaplet, Laval, France. Filed May 29, 1894.

550,868. Automatic Electric Switch for Railways. Robert V. Cheatham, Louisville, Ky. Filed March 7, 1895

ELECTRICITY.

Vol. IX. NEW YORK, DECEMBER 18, 1895. No. 23

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, President.
L. J. MONTGOMERY, Secretary.

Publication Office, - - 6 Park Place, New York.

Editors: { BURTON E. GREENE.

EDITORIAL NOTES.

Gas Engine Men and Business.

Electricity has from time to time noted, and the correctness of our observations has been confirmed by all who have sought to add to their knowledge of the gas engine business in America, that it is next to impossible to obtain from manufacturers such information as will enable one to compare the performance of the gas engine with any other type of prime mover used in power generating plants. Of electrical publications Electricity was the first, as it has been the only journal, to point out to the at times obtuse, but always over-cautious, gas engine manufacturer the possibilities of the gas engine in the electrical industry. If the experience which has come to us as a result of our labors in the gas-engine-electric missionary field has been discouraging and disgusting, it has been none the less so for one of our contemporaries, to whom the honors of prophecy are quite as fittingly due.

Progressive Age, the zealous champion of the gas interests, profiting not by the lessons Electricity has learned, recently sought to secure information, the publication of which was intended for "the benefit of gas-engine purchasers in general and the gas companies in particular," and the aim of which was to give "the exact status of the gas engine market of the day so far as could be done with the necessary exclusion of all questions of price." The conclusions reached by our contemporary are so interesting that we give them somewhat at length:

> The compilation of the article in question revealed a surprising lack on the part of the gas-engine builders of two important features of equipment for the business. One was any apparent anxiety or desire, excluding individual exceptions, to publish information concerning their engines; and the other was a wofully apparent lack of that information.
>
> The first cannot be explained away by any modest reservation on our part as to the value of publication in these columns, because the insertion was to be free and therefore of unbalanced desirability; while either lack of interest or of data led to a corresponding paucity of information in their regularly distributed circulars. Out of eighty odd makers to whom application was made, less than five took the trouble to point out the desired characteristics of their product, the majority replied with catalogues while a few either openly refused co-operation or let pass unheeded repeated applications enclosing samples of the work in progress. Perhaps the weeding thus accomplished automatically was more perfect than could have been attained by scientific comparison.
>
> The lack of exact knowledge of their own engines, as evidenced by these circulars, is almost without exception. In a great many cases there was barely sufficient idea of the operation, valve-motion, etc., given to enable one to classify the engine properly; any estimate of its probable value was out of the question. The circular usually started off with a disquisition on the desirability of gas-engines in general, and ended with assertion of the superiority in every respect of this one in particular. If statements of fuel consumption were made, they generally took the form of "so and-so per cent. better than any other engine," words which, we blush to explain, are absolutely meaningless, except that to the shrewd buyer they would demonstrate a desire to substitute circumlocution for candid statement. When figures are given they become equally meaningless, because all mention of the conditions of the test—the quality of gas, the size of engine, the character of load, the precautions taken against error, etc., etc.—is omitted. Indicator-cards, though not frequent, never contain the data requisite for proper use, and the further refinements of friction-tests, missed-ignition records, etc., are never thought of. The circulars even rarely contain cross-sections of cylinder or valves, and very few give any adequate idea as to methods of construction, material, etc.

For Electricity to have declared that "the gas engine manufacturer, as a business man, has been unique," may not savor as much of *lese majeste* as for *Progressive Age* to express such an unfavorable opinion of his sagacity, technical knowledge and business competency, but it is quite as near the truth.

* * *

The Wiring Question in England.

A discussion has been inaugurated in electrical circles in England over the relative merits of concentric and conduit wiring for interior work, which, if it serves no other purpose, makes apparent the fact that the champions of the respective systems are agreed as to the faults of the present English practice, but differ as to the methods to be employed in securing a higher standard of work. The discussion had its inception at the recent meeting of the London Institution of Electrical Engineers, when two papers, embodying the views of Mr. Samuel Mavor and Mr. Fred. Bathurst were presented, the former urging the advantages to be gained from the employment of the concentric system, the latter pleading the cause of interior conduit.

As stated, both authors candidly admit that the state of the wiring art in England falls far short of that standard of excellence which engineers and others, uninfluenced by considerations of first cost, have long held, in both England and America, to be essential to the highest degree of safety. In this respect "their strictures," says the London *Electrical Review*, "are not one whit too severe, nor do they even touch the worst examples to be found." Viewed from the local standpoint, or at least as the views are reflected by the London technical press, it would appear that "a warm exchange of opinions," and "an informing debate" will ensue before our English friends have determined which is the safer and better system of interior wiring to be used. It is plainly evident that the question of cost will be an important, if not controlling, factor in this discussion, it being contended for the concentric system that "no consideration except its greater cost could have prevented its general use" while "the great objection to any conduit system is the expense attaching to its adoption."

Interesting as this discussion may be to English electricians, the decision to be eventually reached will have more of interest to electricians in America than will the arguments advanced by the respective advocates. In this country the questions involved in the discussion have long been settled. It is certainly true that to-day there are few, if indeed any, American engineers who would seriously consider, much less advocate, the use of the concentric system for interior wiring. Their conclusions would not be influenced by the question of cost, but rather by the insuperable mechanical difficulties inherent in the system. The interior conduit has solved the problem of efficient, safe and economical wiring here. Without claiming gift of prophecy, we may venture to assert that our English brethren will sooner or later reach the same conclusion.

* * *

Scientific Fiction. With persistent regularity certain of the lay press, whose knowledge of electrical and mechanical science and art is as fearlessly expounded as it is wonderfully conceived, astonish the world and amuse the profession of engineering by an exposition of heretofore unheard-of wonders soon to be accomplished. Unknown sources of power and methods for utilizing them are revealed by these tireless searchers after untruth, with an elaborateness of detail rivalled only by the writings of Jules Verne. Keely, Pennock, Van Choate and other discoverers who have ruthlessly cast aside the limitations of the laws of physical science and accomplished the impossible and improbable, are to these chroniclers of scientific fiction veritable well-springs of joy, if not of inspiration.

To our erudite contemporary, the *Transcript*, of Boston, the scientific world in general, and New York City in particular, must ever be indebted for a solution of a problem which has long perplexed our ablest engineering talent. Reference is here had to the utilization of the wave-power along the water front of this city for purposes of generating electricity, practically without cost, to do "all the mechanical work in the factories and machine shops, and to run all the railroad lines in the city and suburbs." Startling as it may seem, "this power is wasted." But the waste, which has continued for a period antedating even the founding of Boston, or the later birth of the editor of the *Transcript*, is to cease, for "all that is required is to store this immense power, and turn it into profitable use." Just how this "greatest feat of modern engineering" is to be accomplished is thus explained by our New England exchange:

> The problem presented differs somewhat from that of Niagara. The tides are periodic, and not constant, and the power would have to be collected at the times of its greatest exertion and stored for later use. The Niagara people have already proposed to run a line to New York to do what the tides of the Hudson and East rivers would accomplish right at home. Either undertaking is a large one, requiring the expenditure of millions of dollars. But the results would more than justify the outlay. An inexhaustible supply of power from outside would prove a blessing that could hardly be appreciated to-day. The present cumbersome delivery of coal to factories and private houses would be abolished, and a clean, neat, pleasant method substituted. The plant could be located at some convenient place in the suburbs or along the river front, where the city air would not be vitiated and poisoned by coal gases, dust and smoke.
>
> The present outlook is that the Niagara Falls power company will in time run an electrical conduit to New York to supply the motive and lighting power of the city and suburbs, unless some enterprising body of capitalists undertakes to utilize the wasted power of the tides nearer home. A conduit capable of bringing 100,000 to 200,000 horse-power from Niagara would cost more than a four-track steam railway. The investment of a similar amount in collecting and storing the power of the tides in the North and East rivers ought to yield better results.

Engineers may find in the above an absence of detail ordinarily found in a description of gigantic engineering works, but the fact must be borne in mind that the proposed enterprise is not an ordinary one, nor is the originator of it an ordinary person.

* * *

Trolley Progress in Connecticut. The annual reports of the street railways of Connecticut, recently filed, show that the street railway financier and promoter has not been unmindful of his opportunities in the Nutmeg State. That the 147 miles of street railroads in the State have increased to 302 miles within the short space of 33 months, and that the horse has become obsolete for purposes of street-car traction, are of themselves interesting facts. Striking as these evidences of the increasing growth of the industry may be, a study of the financial status of the operating companies is of more absorbing interest.

To the statistically inclined the following tables are commended as providing vast possibilities for purposes of comparison. Incidentally they show the amount of the capital stock of the companies, the amount of stock issued for cash, and the amount of bonds floated and the floating debt:

	Stock issued.	Floating debt.
Middletown St. R. R. Co	$75,000	$6,368
Derby St. R. R. Co	150,000	24,300
Norwalk St. R. R. Co	50,000	......
New Haven & Centerville R.R Co	300,000	9,908
Winchester Avenue R. R. Co	400,000	88,576
New Haven St. R. R. Co	100,000	......
West Shore R. R. Co	50,000	73,339*
Fair Haven & Westville R. R. Co	600,000	120,000
Bridgeport Traction Co	2,000,000	70,000
Bristol & Plainville R. R. Co	100,000	90,000

Hartford & West Hartford R.R. Co.	247,000	105,000
New London St. Ry. Co	150,000	110,000
Norwich St. R. R. Co	250,000	265,000
Southington St. R. R. Co	20,000	20,000
Total	$2,048,000	$7,367,000

From these tables it will be observed that by selling $2,048,000 worth of stock for cash, and on the issue of $5,726,240 for construction and other purposes, the Connecticut financiers have been able to bond the street railways of that State to the extent of $7,367,000, while at the same time a floating debt of $1,186,177 has been incurred.

Elaborate calculations are therefore not required to show that the capitalization liabilities of the 24 operating companies aggregate $16,327,177, an average, in round numbers, of $53,000 per mile of track. The actual cost of construction and equipment, as certified by the companies' reports, was $10,550,868, or approximately $35,000 per mile. The capitalization is thus seen to be about $18,000 per mile in excess of the entire cost of the roads.

Beyond this fact it is not necessary to go when seeking to discover why but thirteen of the twenty-four roads paid dividends out of the earnings of the year. Interest on bonds alone cost $238,963. Adding to that the cost of operating expenses, taxes, etc., there remained of $2,098,583 gross earnings only $171,206 for dividends, or a trifle over 2 per cent. on the entire capital stock issued.

The Finale at Ottawa.

B. E. Sunny Buys and Will Remove the Ottawa Street Railway.

(From the Free Trader, Ottawa, Ill.)

Saturday afternoon, before a crowd of curious spectators, Al F. Schoch, receiver, offered the real estate and personal property of the Ottawa Electric Street Railway, including its franchise, according to order of the United States Circuit Court directing the sale of the property under the foreclosure of the Mercantile Trust Company's $75,000 mortgage, to the highest bidder for cash, the purchase being subject only to a tax deed of $1,222, the taxes of 1894, for which the road was sold under an agreement last spring. The sole bidder was the General Electric Company, owner of three-fourths of the stock and bonds, which, by its agent, B. E. Sunny, its Western manager, bid $7,500, presumably as a "starter."

Receiver Schoch looked into the faces of the crowd with a half sad, half amused smile and pleaded for a bid of $8,000 but the crowd was silent. Mr. Sunny refrained from raising his bid—no one expected he would do so—and the road was given to the General Electric Company without opposition.

Interviewed by the *Free Trader* Mr. Sunny said:

"The General Electric Company cannot operate this railway at a profit and does not intend to try. If it is not purchased of us before we are ready to dispose of it in our own way, we will tear it up and remove it from the city. We would have done so long ago were it possible."

"When do you expect to do this?"

"Shortly after the court confirms the sale."

Mr. Sunny is the personal mouthpiece of the General Electric Company and its will is expressed through him. Ottawa need expect nothing from him or it for she will receive nothing. The company, according to Mr. Sunny, wished to remove the tracks and machinery from the city when it ceased operating the road but was prevented from so doing by legal obstacles in the shape of claims and bondholders and creditors. He states, as he stated some time ago, that the road can be purchased of his company for $25,000, as the material of which it is constructed, together with the machinery, is worth that amount at second hand.

But, whether or not it is worth $25,000 or $50,000, or 25 or 50 cents, it is unquestionably a stubborn fact that the General Electric Company will not operate it in Ottawa now or at any other time. Whether or not it has committed fatal errors in management does not alter the situation in its eyes—it does not desire to operate—it will not operate.

Subsequently to the sale Receiver Schoch filed a report in the Federal Court, recommending the acceptance of Mr. Sunny's bid.

The Mayor of Port Huron and the Mayor of Detroit.

Some Fun Anent Pingree's War on Street Railroads.

The following letter has been mailed to all Mayors of Michigan cities by the Hon. N. S. Boynton, Mayor of Port Huron:

My Dear, Good Mayor: I am sure you, as well as myself, realize that the good Mayor of Detroit is having an unprecedented struggle with that octopus, the Citizens' Street Railway Company. We all hope that he will succeed in his determined and undying efforts to secure "eight for a quarter" tickets and put down the street car strike or boycott which is now on in that city.

I am further quite sure all the really good and peaceably inclined and well disposed citizens everywhere desire that this long drawn out and stubbornly fought contest or strike should come to a close, so the daily papers of the metropolis of the State of Michigan can give some of their space to international, political, social, religious and other burning questions of the day.

Now, therefore, in the interest of peace, harmony and good fellowship, and with a view of assisting the Mayor of Detroit in amicably bringing about a peaceable solution of the controversy, the Mayor of Port Huron would ask all the other mayors of all the other cities in Michigan and adjoining States to join with him in tendering to the good Mayor of Detroit their diplomatic services and influence in securing a cessation of hostilities long enough to arbitrate the differences between Detroit's mayor and Tom Johnson, or, if possible, secure a treaty between the two on the lines of the treaty of 1817 between Great Britain and the United States. In doing this, the Mayor of Port Huron is only following the example set by the good Mayor of Detroit in calling upon all the Mayors of the country to assist him in arbitrating the great railroad strike of 1894, and going there himself to accomplish that result.

The undersigned sincerely hopes you will not turn a deaf ear to this appeal, but will respond quickly. The present condition of things in the beautiful city of the straits demands prompt action. If the bitter controversy is not settled by arbitration or treaty, the Mayor of Port Huron fears that every street car on every line in that city will be turned into a land war ship, bristling with all the modern armaments of war vessels, flying respectively the union jack and the stars and stripes, carrying destruction and death in their wake.

What do you say? Shall we make an effort to bring peace on this part of the earth and good-will toward man and womankind throughout this nation? Awaiting an early and favorable reply, I remain yours, very, very truly.

Encouragement for G. E. Stockholders.

(From the Boston News Bureau.)

The General Electric Company is doing a little better than $1,000,000 of gross business per month, and is striving for a fair manufacturing profit, but is not getting it on all lines. It is probable that the gross business for the fiscal year will foot up slightly above $13,000,000, which at prevailing prices means a very large tonnage of electric goods.

There ought to be $2,500,000 manufacturing profit in this, but it is doubtful if such will be found when inventories are taken at the close of the year. However, it is expected that 8 per cent. will have been earned upon the common stock this year besides interest and full dividend on the preferred. Nothing, however, will be done this year toward the payment of any dividend on the preferred stock. They will be allowed to accumulate thereon for some time. It is felt that the matter can be better adjusted when the company has clearer views as to dividend policies than at present.

Stockholders may take some interest in comparing the above, which may be said to be a semi-official declaration of the General Electric Company's future dividend policy, rather than a truthful statement of the volume of business being done, with the annual balance sheet of Allgemeine Elektricitats-Gesellschaft of Berlin, Germany. With a capital account of 20,000,000 marks and a debenture account of 4,788,000 marks, this company earned during the past year a net profit of 2,677,318 marks, out of which 11 per cent. dividends were paid; 110,000 marks were devoted to bonuses to the staff and to the pension fund, and 67,318 marks were brought forward to the current year.

In addition to borrowing the name of its German contemporary, the American company would do well to copy some of its business methods.

* * *

THE letter printed below has been referred to in ELECTRICITY. The circular mentioned is the one which has become familiar, designed to awaken enthusiasm among "the boys who are in the real pot," and providing for the greasing of Common Councils:

ALBANY, N. Y., Oct. 25, 1895.

EDITOR ELECTRICAL DEP'T N. Y. HERALD,
New York City.

DEAR SIR: To correct statements made by Mr. Clarkson as stated in clipping from *Herald* of Monday last, I send you herewith circular which came direct from the Standard Telephone Company's office on July 27th last. No paper can expose the inside work of this promotion company as well as the *Herald*, and it should be done to prevent innocent parties being placed in false colors to the public. Ask them what telephone patents they own or control. I am told the Phœnix Interior Telephone Company, 131 Liberty street, has made what few instruments the Standard Company have put out. They may be able to give you some information.

Yours truly, W. V. D.

Why did not the New York *Herald* take this matter up?

* * *

Every Word True.

Why G. E. Stock is Selling at 30.

(From the New York Daily Stockholder.)

In another column of the *Daily Stockholder* we print an article on General Electric, taken from our interesting contemporary ELECTRICITY. It is an able presentment of facts relating to the General Electric Company. Every word is true, and we dare say the officials will not take any exceptions to the journal's statements.

It explains why General Electric stock is selling around 30 with every prospect of lower quotations for it. Our own opinion is that with several years of back dividends due on the preferred stock, the common will have to be cut down or assessed, and that at no distant day.

* * *

G. E. Company Wants Its Share.

(From Trenton, N. J., Special to New York World.)

The General Electric Company of New York is trying to make ex-Mayor Frank Magowan, of this city, give up $75,000 of $160,000 he made by a little scheme. Frank L. Maguire is a co-defendant.

The contracts for the electric lighting in Trenton were about to expire in 1892, when Magowan organized the Edison Light and Power Company, with himself, Maguire and William P. Hayes as stockholders. Only about $500 was spent in the enterprise.

Magowan succeeded in getting franchises that so frightened the People's Electric Light and Power Company, which had the contract from the city, that it paid him $150,000 for the franchises and $10,000 for organising his company.

The General Electric Company alleges that Maguire was acting as its agent in dealing with Magowan and that it is entitled to one-half of the $150,000.

* * *

More G. E. Combinations.

The Schenectady *Union* volunteers the information, said to have come from "a very high source," that the officials of the Schenectady Locomotive Works and the General Electric Company have taken steps toward a consolidation of interests as far as the manufacture of electric locomotives are concerned.

Assessment of Patent Rights Held to be Illegal.

The argument on the application of the Edison Electric Light Company of Brooklyn to review the assessment on its personal property was heard by Justice Bartlett of the Supreme Court this week. The board of assessors had assessed the real estate of the company for the year 1895 at $794,699 and the personal property at $1,070,650. In opposing these figures the company alleges that it total gross assets are $3,179,841. That from this sum $2,190,971.81 must be deducted as invested in real estate here and in the State of New Jersey; $945,000 as invested in patent rights; $500,000 in bonded indebtedness and other items, which in all make the exemption claimed exceed the gross sum of $706,597.

The assessors fixed the value of the patent rights not at their actual value, but at the value allotted by the company on its own books. The board would not agree to deduct $50,000 for the capital stock not yet issued, and pretended to assess the personal property at $1,070,650. This the company alleges, was a grossly unfair discrimination, as no other corporation had ever had its patent rights assessed before. The company claims that the tangible personal property liable to taxation is only $173,520.69, yet the assessment of $400,000 had been levied on it. That was at an increase of $200,000 over the figure set for last year.

Attorneys for the company contended that taxation on patent rights was contrary to law and without authority of any kind. Judge Bartlett reserved his decision.

For a Government Postal Telegraph.

Perhaps one of the most important bills that have been introduced at the present session of Congress is one by Senator Kyle, of South Dakota, asking that a Government telegraphic system shall be established within the United States. The bill names the Secretary of State, Secretary of War, and the Postmaster General as a Board who shall cause to be located four trunk lines, which will connect the Northeastern, Northwestern, Western, Southwestern and the Southern sections of the United States with Washington City. Local telegraph offices shall be erected and maintained wherever necessary along the lines.

It is further provided that the Government telegraph shall be operated as a part of the postal system of this country, the operation to be under the direction and control of the Postmaster General. The rates shall be established by the above named Board. The line is to be constructed and kept in repair under the direction of the Secretary of War and through a Corps of Engineers detailed for that purpose, and shall be under the same general provisions of law as other public works of the United States. The sum to be appropriated for this work is $5,000,000. This act will not prohibit individuals or corporations from carrying on the business of operating telegraph lines.

A Hydraulic Air-Compressor.

The *Buffalo Express* states that C. H. Taylor has invented a hydraulic air-compressing system whereby power can be developed at much less cost than by turbines. The air is compressed by the direct action of falling water, without the aid of any moving machinery. The water is conveyed to a compressor by an open flume or through a pipe supplying a tank or stand-pipe round the headpiece of the compressor, where it can attain the same level as the water in the dam or source of supply. There are a number of small, horizontal airpipes around the headpiece. These draw their supply of air through larger vertical pipes, which extend above the surface of the water and open to the atmosphere. As the water enters this down flow pipe and passes the ends of small air-pipes, it draws in the air constantly, in the form of small uniform globules, which become entangled in the descending water, are carried down to an air chamber at the bottom of the pipe, compressing the air by weight of the water surrounding the globules, according to their depth below the tail-race water level, until they reach the point of separation. The air chamber at the bottom is sufficiently large to allow the air to rise to the surface of the water therein. Thence the air is taken through a pipe for transmissions to be utilized as power or for other purposes.

The American Street Railway Association.

At a meeting of the Executive Committee of the American Street Railway Association held in St. Louis, December 9, the Southern Hotel was selected as the headquarters of the Association during the next annual Convention. The meetings will be held in the Olympic Theater, across the street from the hotel. The exhibition hall has not been selected as yet, but will be in the near future.

The local committee at St. Louis are straining every nerve to make the next the most pleasant Convention yet held. The Executive Committee think they have selected subjects for discussion that will not fail to interest the most skeptical. It is suggested that delegates and visitors secure hotel accommodations at as early a date as possible, as Mr. Lewis, manager of the hotel, will make reservations for all who apply.

A Philadelphia Trolley Strike.

The employés of the Union Traction Company went on strike on the morning of the 17th inst., to enforce their demands for shorter hours, extra pay for snow plow and sweeper work, "trippers," recognition of the union, and other grievances formulated by the Amalgamated Association of Street Railway Employés. President Welsh declined to treat with the Association. The various depots of the Traction Company are guarded by special policemen. Cars are being run at long intervals on some divisions of the company's system.

The only line in Philadelphia that is not controlled by the Union Traction Company is the Hestonville, Mantua & Fairmount Passenger Railroad Company, which operates on Arch, Race and Vine streets.

Electrical Engineering at the Cape.

An Electric Lighting and Power Act has recently been passed at the Cape of Good Hope, authorising regulations for the safety of the public.

THE TROLLEY DECISION.

An Abstract of Judge Townsend's Opinion.

Excluding the history of the case, which has already been exclusively published by ELECTRICITY, also the review of various other inventions referred to, the important points in the decision of Judge Townsend in the suit of the Thomson-Houston Electric Company vs. the Winchester Avenue Railroad Company are as follows:

The combination of devices described in patent No. 495,443 is of great utility in the art of electric railroading, and has superseded every known apparatus. The experts for defendant admit that they do not know that any one other than Van Depoele, prior to September, 1885, had proposed to equip the car with a contact device mounted on the end of a long pole upwardly pressed by means of a spring, and to hinge the pole on a car and make it turn on a pivot. . . . The burden of proof is on the defendant to overcome the oath of the inventor, and this it has failed to do. . . .

The new problem presented was how to make practicable the electrical propulsion of an electric railway by a continuous contact under all the conditions presented by crowded streets, sharp curves, complicated switches, rough roads, reversed lines of travel, and the necessity of a continued upward pressure of from eight to fifteen pounds. The solution was accomplished by a long rigid arm upwardly pressed and capable of a universal movement. "This arm," says the inventor, "possesses substantial practical advantages over any other means yet proposed for establishing moving contact between a vehicle and a stationary supply conductor, in that by the use of a hinged flexible arm much greater freedom of movement is compatible with the maintenance of a positive mechanical connection and electrical contact between the vehicle and supply conductors."

Prior inventors in the same art had shown a similar contact with a rail under the car, but they failed to indicate or claim the element of spring pressure or capacity for lateral motion. Prior inventors in an allied art had shown by paper patents the principle of continuous or interrupted contact with such limited provisions for lateral or vertical motion as to be impracticable. Prior inventors in a remote art had shown in tethers for animals and in office chairs, spring pressure and universal movement. But the inventors in the art of electrical propulsion, signals, or telegraphs had failed to provide for an operative contact device at a distance from the car required for the operation of the under-running trolley road, except by unwieldy and impracticable structures on the roof of the car. They had failed to adequately provide for considerable variations from practically straight lines of travel. In their later attempts to do so they had constructed or adopted contrivances which departed from the earlier devices now claimed to show lack of patentable novelty, and thereby furnished strong proof that the changes made by Van Depoele were not obvious ones. Defendant's expert is forced to admit that the advantages of an underrunning trolley were not obvious, and that the earlier constructors must have been in doubt as to the efficiency of such a system, and that the prior underrunning overhead devices would have led a person away rather than towards an upwardly pressed hinged conductor. In these circumstances the use of old principles does not fall within the rule of a double use. The old use was not intended for nor adapted to the conditions of the new use; it produced in part only the results of the new use.

Van Depoele discarded the elevated wheel and springs of his earlier patent and broke away from his own towed trolley and those of Siemens, Finney, Henry and others, and reversed the underrunning trolley of Daft and Edison, and added lateral motion thereto, and went back to the overlooked art of animal tether or the limited and impracticable art of railway signals, and selecting and combining certain elements of these various contrivances, modified and adapted them to a new purpose, and thereby disclosed to the public a practically operative means such as the whole world of electrical inventors had theretofore sought in vain, and which has gone into universal use throughout the country. He made an invention within all the rules applicable to this question. I have been unable, therefore, to adopt the view of counsel for the defendant that the art of conducting electricity from a conductor to a translating device on a moving vehicle was sufficient to enable the skilled mechanic to construct the device of said patent.

The defendant, while denying patentable novelty and urging that even if there be an invention it is substantially the same as that covered by former patents, chiefly relies upon the claim that within the meaning of Miller versus Eagle Manufacturing Company, the invention of the later patent is inseparably involved in the invention of the earlier one.

In the case at bar the special combination described and claimed in the earlier patents was distinct and separate from that of the later generic invention. They stated the new problem presented to the inventor in the practical development of his invention, the construction of an improved switching plate device, and the means for its application which the patentee had a right to protect. While they were dependent for their operation upon the original broad invention of the earlier application, but later patent, they were not otherwise inseparably involved.

In Miller versus Eagle Manufacturing Company the function of increasing lifting effect . . . was involved in the patent in the sense of identity of structural combination and action. The patentee attempted by a later patent to extend the monopoly of an effect essentially brought into operation. . . .

The decision in Miller versus Eagle Manufacturing Company merely affirmed the well settled law that two patents for the same invention could not issue to the same patentee. There is nothing involved therein which affects claims in suit herein. If any departure from the settled rules of construction is justifiable in any case, it should not be allowed for the purpose of destroying a meritorious invention embodying a construction which first made practicable the operation of the trolley railway under all conditions, and which is now employed on more than five hundred electric railways in this country, representing an invested capital of about $500,000,000.

Of the second patent, No. 495,383, Judge Townsend, after a review of the case, said:

The reason for the adoption of the device of this second patent follows as a corollary of the foregoing conclusions. Its adoption results not from its patentable novelty but from its practical utility in connection with the main invention. The doctrine that utility in the absence of patentable novelty is immaterial is especially applicable where the sole foundation for the claim of utility lies in the mere mechanical adaptability of a well-known device to a novel invention protected by a valid patent.

English Definition of Low Pressure.

Lord Kelvin, Mr. W. H. Preece and Major Cardew, the committee of experts appointed by the London Board of Trade, have presented their report on the questions which were referred to them as a result of the recent conference on the proposed new electric lighting regulations. The principal matter on which the committee were asked to advise was as to the definition which should be officially laid down to constitute "low pressure." As presented to the conference, the revised regulation of the Board of Trade proposed that a pressure which could not at any time exceed 300 volts if continuous, or the equivalent of 150 volts if alternating, should be deemed a low pressure supply; but the Institution of Electrical Engineers urged that 600 volts should be accepted as the low pressure limit. The Electrical Committee of the London Chamber of Commerce advised that the low pressure limit should be raised to 500 volts, and other experts considered that, in view of the advance made in electrical science, it was no longer necessary to draw any distinction between alternating and continuous currents.

Claim That the Patents are Unlawful.

Some time ago Elias E. Ries and Albert H. Henderson brought suit against the Metropolitan Railroad Company of Washington City for using certain electric appliances on its cars in violation of patents issued to the complainants. The company has filed its answer, claiming that the inventions were already patented here and in foreign countries before the alleged improvements, therefore the patents upon which the suit was brought were unlawfully issued.

Our London namesake states that the congregation of a Presbyterian chapel at Nottingham have celebrated the introduction of the electric light into their place of worship by a special service, in which the light was duly extolled and appropriate morals drawn from its superiority to all other known illuminants. A special preacher was brought down from London for the occasion, who seems to have treated his subject in a philosophical spirit very unusual in such places.

LEGAL NOTES.

Another Feeder Patent Suit.

John I. McDuffee, trustee for Susan E. McDuffee, Alfred H. Williams and William M. Schlesinger Selwyn, formerly William M. Schlesinger, through their attorneys, have filed a bill in equity in the United States Circuit Court at Philadelphia in a suit against the Union Traction Company of that city for alleged infringement of patent. It is claimed that the patent controls the operation of trolley roads by means of the sectional feeder system.

In the bill the Philadelphia Traction Company, which forms a part of the Union Traction Company, is exempt from liability under the suit, for the reason that while the former company was operating independently suit was brought against it for infringement of this patent. After considerable testimony was taken the suit was settled by the Philadelphia Traction Company buying a license under the patent.

A jury in the United States Circuit Court in Brooklyn, N. Y., has rendered a verdict for $6,899.33 in favor of the Abendroth & Root Manufacturing Company, who were defendants in a suit brought by the Edison Electric Lighting Company of Philadelphia for $34,035.39 for damages alleged to have been caused by defective boilers.

The Court of Appeals of New York State has decided that street railroad companies are liable for damages occurring to passengers who may be injured while riding upon the platforms of surface cars and smoking, provided that the company affected, while prohibiting smoking inside closed cars, allows smoking on either platform and collects fares from persons occupying either platform.

At Cincinnati a damage suit brought by Mary A. Wolfe against the Cincinnati Edison Electric Company for loss of rent and damage to property which the plaintiff claimed was due to the jar and noise of the machinery in the defendant's power-house, rendering her building untenantable, was recently given to a jury in Judge Buckwalter's court, whose verdict was in favor of the plaintiff on the following basis: "Present market value of the property, if no nuisance existed, $13,500; its present value $6,000; diminution because of nuisance, $7,500; damage from loss of rent, $1,900; personal damage to plaintiff because of ill-health and discomfort, $705; total, $10,105."

Judgment for $5,239.00 has been entered against the Elizabethtown Electric Light Company, Elizabethtown, Pa., in favor of the Westinghouse Electric and Manufacturing Company.

W. H. Bennett has been appointed receiver of the West Side Street Railway Company, Milwaukee, Wis.

E. R. Anson has been appointed receiver of the Consolidated Street Railway Company of Salem, Ore. The appointment was made upon petition of the First National Bank of Salem, which held accommodation notes for $8,712 due and unpaid.

Gas Engines in Switzerland.

The electric railway at Lausanne, Switzerland, is operated from a power house in which the dynamos are driven by two gas engines of 130 H. P. each. These engines use producer gas. The dynamos are belted to the flywheels. The working is said to be very economical, and the best result obtained has been an expenditure of 1.2 lb. of anthracite coal per horse-power hour in ordinary service. The engines are run on an average 18 to 20 hours per day. A careful calculation has shown that the amount of fuel used is 4.5 lb. of anthracite per car-mile.

A Postal Car Excursion.

A short excursion was given by the Brooklyn Heights Railroad Company on Monday, December 16, at 3:30 P. M., in the new postal cars which have been built by the company for the use of the Post Office authorities in Brooklyn.

A 3-Cent Fare if no Seat is Provided.

A set of resolutions was introduced in the City Council of Chicago this week providing for a 3-cent street car fare for all street car passengers for whom seats are not provided. The resolutions were referred to the Judiciary Committee.

TESTS OF A 10 HORSE-POWER DE LAVAL STEAM TURBINE.*

BY WILLIAM F. M. GOSS.

The De Laval steam turbine experimented upon constitutes part of the permanent equipment of the Engineering Laboratory of Purdue University, and the present paper is based upon data secured chiefly through the assistance of Charles E. Bruff, B. M. E., author of the thesis "Tests of a 10 Horse-Power De Leval Steam Turbine."

In the De Laval steam turbine jets of steam, delivered from suitable nozzles, are made to impinge against the buckets of a light turbine wheel. The steam enters the buckets from one side of the wheel, and passing through is discharged or "exhausted" from the opposite side. The arrangement of nozzle and wheel is shown in Fig. 1. The motion of the turbine shaft, which under the actions of the jets is extremely rapid, is communicated by gearing to a heavier and slower-moving driving shaft carrying a fly-wheel of small diameter, from which the power of the engine is delivered. Regulation of speed is secured by means of a throttling governor, which controls the pressure of steam admitted to the nozzles.

The important moving parts, with approximate dimensions, are shown in Fig. 2. The turbine wheel is built up of sixty-three steel segments, each carrying a bucket and a portion of the light outside rim. The segments are held in place by means of suitable collars, which grip them on either side. The wheel is mounted upon a long, slender shaft, having sufficient flexibility to allow the system at speed to revolve about its center of gravity, even though this may not agree with the geometrical axis of the shaft. The gear upon the turbine shaft is of steel, solid with the shaft; that upon the drive shaft has its teeth formed in a bronze ring, which is carried by a solid iron center. The smaller gear has twenty-one teeth, the larger one two hundred and eight teeth, giving a ratio of 1 to 9.90476.

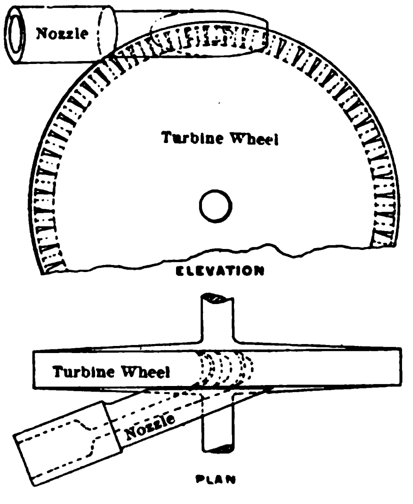

FIG. 1.

The shafts run in bronze boxes completely lined with babbit or other soft metal. To assist in the distribution of oil a spiral curve, the pitch of which is about half the diameter of the journal, is cut into the metal of the bearing. The outboard bearing on the turbine shaft is closed at the end, and a small pipe runs from the closed end to a point over the gears. The pumping action, resulting from the presence of the spiral oilway, gives a constant, though small, supply of oil upon the gears. The gears do not dip in oil, though the case which encloses them receives drainage from all the bearings.

The governor is connected with the driving shaft, of which, at first sight, it appears to be but an extension. It is shown in detail in Fig. 2. The weights, *W W*, with their arms, *C C*, are in the form of a split cylindrical cup. Upon the outside and at the base of each weight a knife edge, *E E*. is found, which bears upon a suitable surface in the governor frame, *A A*. A spiral spring is fitted at its inner end with two projecting pins, which bear upon the arms, *C C*, of the governor weights. The outer end of the spring is connected with the frame by the threaded plug *D*. When the governor is at rest the concave surfaces of the weights are in contact with the frame, and the tension of the spring keeps the knife edges upon their seat. When the governor is revolving at speed the weights are under centrifugal action and move outward, swinging upon their knife edges against the resistance of the spring. The motion of the weights is taken up by the pin *F*, by which it is communicated, through suitable mechanism, to the governor valve above the engine.

The nozzles which serve to deliver steam to the wheel are four in number, and are so fixed in the frame of the engine as to act upon the turbine at points which are equally distant from each other. Two of the four are provided with stopcocks, which, when closed, put out of action the nozzles with which they are connected. By means of the stopcocks, therefore, the engine may be run under the action of two, three, or four nozzles at the will of the engineer.

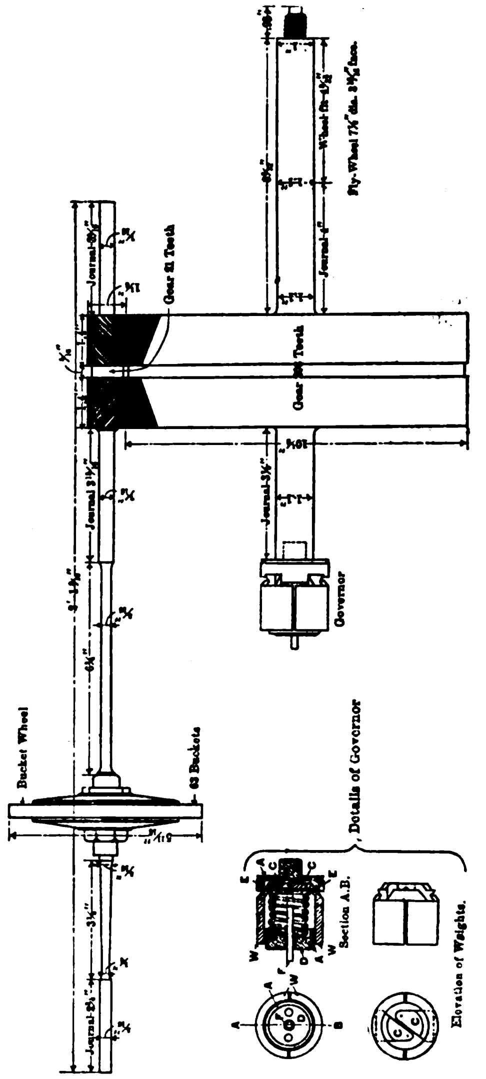

FIG. 2.

The distinguishing feature of the engine is, perhaps, to be found in the form of the nozzles. All are diverging, the throat being approximately two inches from the discharge end. Three have a diameter of 0.138 inch, and one a diameter of 0.157 inch.

THE TESTS.

The power of the engine was absorbed by a pony brake, cooled by constant streams of water. The exhaust steam was piped to a Wheeler condenser, open to the atmosphere. The water resulting from condensation was drained into tin buckets, which were changed and weighed at regular intervals. Gauges were used to show the steam pressure both above and below the governor throttle, the former giving the pressure available at the engine, and the latter the pressure under which, in consequence of the action of the governor, the steam was admitted to the nozzles. A manometer was also attached to the exhaust pipe, but as this pipe is large (3 inches diameter) and the connection with the condenser close, the observed pressure was never appreciably different from that of the atmosphere.

The boiler pressure for all efficiency tests was 130 pounds by gauge, for which pressure the particular nozzles used were designed. The rated speed of the fly-wheel is 2,400 revolutions per minute (23,771 for turbine wheel), but this standard was not maintained for all the tests. The governor was adjusted several times as the work progressed, and it was not until several tests had been run that the proper speed was secured. It is believed, however, that the differences of speed recorded do not materially affect the value of results for purposes of comparison.

The tests are grouped into three series, the first including those for which all four nozzles were in action, the second those with three, and the third with two. The several tests in each series were intended to vary from each other only in amount of power delivered from the wheel. All tests were of thirty minutes' duration, and all observations were taken at five-minute intervals.

With all four nozzles in action, and with the engine developing a little more than its rated power, the steam consumption per horse-power hour was as low as 47.8 pounds. In comparing this result with results obtained from other engines, the small size of the engine tested should be kept in mind, and also the fact that the rate of consumption stated is based upon brake power. The efficiency of the engine falls off rapidly as the load is decreased, and, as would be expected, the effect is not marked when all the nozzles are in action. This may best be seen by the heavy curves shown in Fig. 3. Assuming the nozzles to be cut out of action one at a time, as soon as the reduction of load becomes sufficient to permit the work to be done without them, the minimum steam consumption at different loads, for the boiler pressure and speed employed, is represented by the broken line *fgdebc*, Fig. 3. Again, if instead of four nozzles, an infinite number could be employed, and if the governor could be arranged so as to regulate the number in action rather than the pressure admitted to them, the steam consumption of the engine in question might be made to follow a line somewhat similar to the light broken line *gec*. But the heavy lines indicate the results which were actually obtained.

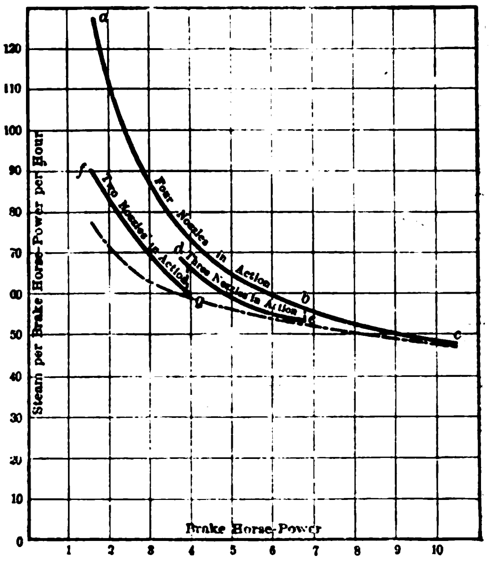

FIG. 3.

The engine requires very little attention and is almost noiseless in action. The governor is quick to act, and its speed regulation appears to be fair, except when changes of load are large and suddenly made. After such a change, the engine requires a little time before settling down to steady running under the new conditions.

---

*Abstract of a paper read at the New York Meeting of the American Society of Mechanical Engineers, December, 1895.

As the speed of the De Laval engine is high, it is evident that the force in action must be comparatively low. To determine the maximum resistance under which the engine might be expected to start, the brake was clamped upon the fly-wheel so that the latter could not turn within it. Steam was then admitted to the engine, and readings were taken from the scale under the brake arm. The result of this process, of course, depends upon the steam pressure and the number of nozzles in action. With all nozzles, and with a steam pressure of about 125 pounds by gauge, the maximum starting-power is equal to a force of 30 pounds acting at a radius of one foot. With three nozzles the equivalent force was but 21 pounds; with two nozzles 14 pounds.

EUROPEAN INCANDESCENT LAMPS.

Commenting upon the test of European incandescent lamps made by Mr. D. Paisley, the results of which were published in ELECTRICITY October 2, our London contemporary, *Industries and Iron*, says in a recent issue:

> It appears to us as the old question of the test of an engine and boiler on the trial trip and under ordinary working conditions. The test of the engine and boiler is on the trial trip the maker's test, and their test in going across the Atlantic is the owner's test. So it is with lamps. A show test of incandescent lamps selected and sent in by the manufacturers would be a maker's test. The test made by Mr. Paisley of lamps bought in the ordinary way, at the prices which he has marked down, is a purchaser's test. It was meant for this. We did not present the tables as being anything else, and they are very valuable to the public as such.
>
> In the explanatory article we pointed out that the price of the lamp was not the only factor to be considered. The amount of current consumed, and the fall in the lighting power of the lamp, were of the highest importance in view of the low primary cost of the lamp. There was the voltage and the amperes consumed, and these had their commercial value. In fact, the energy or watts consumed by the lamp during its life had to be included in any estimate of value of the lamp. Before we can properly estimate the value of an incandescent lamp, we must know four things—
>
> 1. The primary cost.
> 2. The cost to him of a watt.
> 3. The candle-power of the lamp for the time under consideration.
> 4. The length of life of the lamp in hours.
>
> When these things have been determined, and the tables we gave supplied them, then the purchaser is in a position to know exactly what lamp under his conditions will suit him best.
>
> The question, of course, to the consumer is: What is the total price of a candle-power per hour for any lamp to me? Into this comes the primary cost, the candle-power, the life, and the cost per watt to the purchaser of the lamp. Writing this in mathematical terms we have—
>
> Price per C. P. per hour = primary cost of lamp × cost of watt × number of watts per C. P. ÷ life of lamp in hours.
>
> The table referred to gives the primary cost of each lamp, the number of watts used per candle-power at different stages of the life of the lamp, and the life of the lamp in hours, and therefore all the elements supplied for estimating the value of any lamp in the way shown above. What, of course, is required is the cost of a candle-power for each lamp per hour. We do not propose to set up a comparison between the lamps made by manufacturers, but to show how the value to the purchaser and consumer may be determined. For this purpose we take three lamps made by three manufacturers who have been referred to in this and contemporary journals. The three names are the "Robertson," the "Sunbeam," and the "Edison and Swan," and as it is merely an illustration, we do not select any particular lamp, but those marked 1 in the first set of tests.
>
> Taking, then, the Edison and Swan first, and number 1 lamp of the old manufacture, we find that at the beginning of the test the watts required per candle are 3.83 and 4.7 at the end. The average watts per candle-power is thus 4.26. Assume that the cost of a Board of Trade unit is 8d. The life of the lamp is given as 600 hours. Hence, applying the rule, we get—
>
> Cost of C. P. per hour (Edison-Swan) = primary cost of lamp × cost of watt × number of watts per C. P. ÷ life of lamp in hours
>
> $$= \frac{21}{600} \times \frac{8}{1,000} \times 4.26 = .00119 \text{ pence.}$$
>
> Secondly, taking the Sunbeam number 1 lamp, we find that at the beginning of the test the watts required per candle are 3.5, and at the end 5.7 watts. The average watts will then be 4.6. Taking the same cost, per Board of Trade unit, namely 8d., the life of the lamp is given as 600 hours, and the price 15½ pence. Applying this rule we have cost per C. P. (Sunbeam)
>
> $$= \frac{15.5}{550} \times \frac{8}{1,000} \times 4.6 = .00095 \text{ pence.}$$
>
> Lastly, taking the Robertson number 1 lamp, we find that at the beginning of the test the watts required per candle are 3.94, and at the end 4 watts; the average watts required per candle-power will then be 3.97. Taking the same cost per candle power, namely 8d., the life of the lamp is given as 600 hours, and the price as 16 pence. Applying the rule, we have cost per C P. (Robertson)
>
> $$= \frac{16}{199} \times \frac{8}{1,000} \times 3.97 = .000807 \text{ pence.}$$
>
> Reference has been made in a letter from Mr. F. Walker, referring to the Gabriel & Angenault lamp. The average number of watts required for this is 3.28 per candle power per hour, and the price is 12 pence; so, cost per C. P. per hour
>
> $$= \frac{12}{600} \times \frac{8}{1,000} \times 3.28 = .000528 \text{ pence.}$$
>
> As we said above, we do not put forward these values for the purpose of comparison, but only as an illustration of the manner in which the value of a lamp must be obtained before it can be of any practical value to the purchaser. If an average for all the lamps in the above were obtained and tabulated, the values so obtained would be of considerable practical value to the purchaser.

Subsequently to the appearance of the above, *Industries and Iron* published the following supplementary table, which shows the cost of maintenance of the several lamps tested by Mr. Paisley:

	C. P.	Watts per C. P.	Price.	Tot'l cost per 600 hours at 6d.
			s. d.	s. d.
Gabriel & Angenault, Paris.	13 98	3.51	1 0	15 8
Daylight	14.33	3.61	0 11½	16 5½
Brush Company, Vienna	11.85	4.42	1 0	16 9

Svea & Co	15.18	4.56	1 0	22 3

The conclusions arrived at by the London *Electrical Review* in discussing the tests of English lamps (the results of which were reproduced in ELECTRICITY December 4) has called forth a protest from Mr. John W. Edmundson, managing director of the Sunbeam Lamp Company, London. In a letter to that publication he urged the objections that the tests had been made "without authority" and were unfair because no information was given regarding where the experiments were carried out or by whom they were conducted.

Answering Mr. Edmundson's objections, the *Review* says:

> We were aware that the figures are due to Mr. D. Paisley, whose name we have come across at various times as a contributor to the technical press, and the responsibility for their correctness must rest with that gentleman; but the description of how they were obtained was so straightforward, and the skill required for work of a practical kind is so small, that we see no reason for disputing the data beyond the fact that some of the results do not quite fall in with our preconceived ideas.
>
> Our article was, however, based on more than this. The writer had at various times made tests of incandescent lamps on his own account, and the general results were in accordance with the tenor of what Mr. Paisley gave as his At the same time we must admit that the method of testing is not fully described, and we are not told where the lamps were tried, or the source from which the current used in the test was taken. It is only fair to assume that the measurements were made with commercial instruments of a recognized type, and such instruments do not require any great skill in their use; otherwise it would be necessary to ask for some guarantee that technical skill and ability of a fairly high order were employed, and that the apparatus used was of a suitable kind. But it is expressly stated that the apparatus was checked against standard instruments at frequent intervals, and unless the good faith of the investigator is called into question, one cannot very well criticise direct statements of this kind. One may be permitted to give figures obtained in this way, and offered as being of a practical kind, where others submitted as representing with rigorous exactness certain facts would require a very much more reliable substantiation than has been given so far.
>
> It is at the same time most desirable that tests should in all cases "be made by persons whose names are known, and whose position is a guarantee at once for absolute independence and high scientific attainment." We can judge of these qualifications to some extent by the means taken to publish experimental results. Well known scientific men choose the journal of a learned society, others the columns of the technical press. The authentication of results largely depends on the fulness with which information is given as to the means adopted to obtain data, and the corrective factors introduced.

VARIATION IN ELECTRICAL CONDUCTIVITY OF METALLIC WIRES IN DIFFERENT DIELECTRICS—II.*

BY FERNANDO SANFORD.

The following table gives the change in resistance observed in the above-mentioned wire [see first part of article in ELECTRICITY, Dec. 4] in eight different dielectrics, and the temperature change necessary to account for such variation in resistance upon the hypothesis advanced by *The Electrician*:

Dielectric.	Resistance change.	Equivalent temperature change.
Petroleum	—0.00006 ohm	—0.43°
CS_2 and turpentine	—0.00003 ohm	—0.2°
Wood alcohol and benzine	+0.00005 ohm	+0.36°
Absolute alcohol	+0.00006 ohm	+0·43°
Wood alcohol and petroleum	+0.000075 ohm	+0.53°
Laboratory burning gas	+0.000058 ohm	+0.4°
Chloroform vapor	+0.00005 ohm	+0.6°
Ether vapor	+0.000083 ohm	+0.6°

Following the publication of my first paper upon this subject, a number of measurements were made with a silver wire 1.1 mm. in diameter, using as dielectrics air, petroleum, wood alcohol, absolute alcohol, ether vapor, chloroform vapor, laboratory burning gas, and a mixture of wood alcohol and petroleum. While the same phenomenon was observed as with the copper wire previously used, the variation in resistance was not so great. The most important difference, however, was in the different order of arrangement of the dielectrics with reference to their influence upon the conductivity of the wire. While the copper wire had shown a lower resistance in petroleum than in air, the resistance of the silver wire was very slightly increased in petroleum; and whereas the resistance of the copper wire had been greater in sulphuric ether vapor than in any other dielectric used, the resistance of the silver wire was less in the ether vapor than in any of the other dielectrics. The following table will show the results of the measurements made upon the silver wire:

Dielectric.	Resistance change.	Equivalent temperature change.
Petroleum	+0.00002 ohm	+0.2°
Absolute alcohol	+0.00003 ohm	+0.3°
Wood alcohol	+0.000045 ohm	+0.5°
Wood alcohol and petroleum	+0.000046 ohm	+0.5°
Ether vapor	—0.000025 ohm	—0.3°
Chloroform vapor	+0.000025 ohm	+0.3°
Laboratory gas	Uncertain. Resistance slightly greater than in air.	

The copper wire already mentioned will hereafter be referred to as C_1. Its diameter, as before stated, was approximately 1 mm. In order to observe any possible effect of an increase of surface of the wire, the same tube was provided with a copper wire, of

---

* From the *Physical Review*, Vol. III, No. 4.

1.27 mm. in diameter, hereafter designated as C. The resistance of this wire and tube when the tube was filled with air at 20° C. was 0.02618 ohm. The resistance when the tube was filled with the mixture of air and gasoline vapor used as burning gas in the laboratory was 0.02626 ohm, showing an increase in resistance of 0.00008 ohm.

With the wire C_1, which was of the same length in the tube, the resistances of these two media at the same temperature was respectively 0.03375 ohm and 0.03381 ohm, showing a change in resistance in the burning gas of 0.00006 ohm. This showed that while the surface of the wire had been increased about 30 per cent. the difference in resistance had been increased about 30 per cent.

In order to determine whether all the dielectric in the tube was concerned in the resistance change, or only a thin layer of it in contact with the wire, the wire was withdrawn from the tube, and its surface was very thinly coated with paraffin oil, after which it was replaced in the tube, and a second set of measurements was made with the same dielectrics as before. These measurements gave exactly the same resistance in the two dielectrics. This, together with the fact, mentioned in my first paper, that after the tube had contained a liquid dielectric the wire frequently required a considerable time before it returned to its air resistance, has led me to believe that the phenomenon is due to a very thin film of the dielectric adhering to the surface of the wire, and possibly absorbed to some extent by the wire.

In order to observe whether any effect would be produced by increasing the surface of a given wire, another wire, C_3, 1.27 mm. in diameter, was cut from the same spool as C_2, and was hammered flat to increase its surface. This wire was placed in the tube, and its resistance was measured in the two dielectrics which had been used with C_2, but no increased resistance could be observed in the gas. The wire had been much hardened by hammering, but what change had been produced in its surface is not known.

The next wire used was 1.66 mm. in diameter, and instead of giving an increased difference of resistance corresponding to its increase of surface, its resistance change in burning gas was less than that of either C_1 or C_2. Another copper wire, C_5, 1.27 mm. in diameter, was cut from the same spool as C_2, and was amalgamated upon the surface by immersing it a short time in a solution of mercuric chloride. Its resistance at 20° was 0.02640 ohm in air, and 0.02646 ohm in ether vapor.

The apparatus was next fitted with a copper wire, C_6, about 0.35 mm. in diameter, and its resistance was measured in air, burning gas. and petroleum. In this wire, a change of temperature of 0.1° corresponded to a change in resistance of 0.00008 ohm, so that any resistance change in the different media was marked by possible temperature differences. The mean of fifteen measurements in air, and five in burning gas, seemed to indicate an increase in resistance in the gas of about 0.00001 ohm, but this was probably purely accidental. In petroleum, no difference could be observed.

Thus far I have offered no explanation of the above-mentioned phenomenon. The only hypothesis which I am able to advance, while it would suggest the probability of a difference in resistance in different dielectrics, would hardly account for the irregularity observed in different wires. It will be noticed, however, that while the irregularity in quantitative results is very great, the variations in resistance with wires of the same material are always in the same direction. This is true of the copper wire before and after having its surface amalgamated, and of the silver wire before and after being copper-plated. In the results already referred to, which have been published by Signors Grimaldi and Platania, the variation observed between the air and petroleum resistances of the copper wires used, while less than some of the variations observed by me, were in the same direction. Since the hammering of a wire or the oiling of its surface may produce such a marked change in the degree to which its conductivity is affected by different dielectrics, it is not strange that different observers working with different samples of wire should get very different results; and there is accordingly nothing contradictory in Professor Carhart's results and my own.

The only explanation which I am able to offer is based upon the assumption that the passage of a current through a metallic conductor is accomplished by means of disruptive discharges from molecule to molecule through the intervening ether. These discharges would, like the discharge of a Leyden jar, be of an oscillatory character, although the discharge in one direction would be of much greater intensity than in the opposite, and their rate of oscillation would be affected by the elasticity and density of the intervening ether. While I am not aware that the rate of oscillation of a condenser discharge has been observed to vary in different dielectrics, it is known that the capacity of a condenser does so vary, and this would necessitate a variation in the rate of oscillation of its discharge. In the case of the outer layer of molecules of a wire, the surrounding dielectric would influence the rate of oscillatory discharge between contiguous molecules. If the dielectric should penetrate for some distance into the wire, the rate of discharge of a correspondingly great number of layers of molecules would be affected. That gases at least frequently do penetrate for some distance into metals is well known. In the case of some of the dielectrics used by me, something of this character seemed to take place. This was especially noticeable in the case already referred to of the sulphuric ether vapor and the copper wire. If, however, the dielectric should penetrate to a definite depth into the wire, the difference in resistance should be more marked in fine wires than in coarse ones, since a larger proportion of the molecules would have their rate of discharge influenced by the surrounding dielectric. My own results are too irregular to enable me to decide whether this is the case or not, but the variation in resistance observed in the fine wire used by Grimaldi and Platania was much greater in proportion to the cross section of the wire than in any of the wires used by me.

It seems probable that after a current has been once established in a wire all the molecules in a given cross-section will receive their charges at the same time and part with them at the same time. This would necessitate the same rate of discharge for both external and internal molecules. It might, nevertheless, occur that the hastening or retarding of the rate of discharge of the external molecules would affect the rate of all the molecules of the wire.

One conclusion which seems necessarily to follow from this hypothesis concerning conductivity is that the variation in resistance in different dielectrics should be greater for alternating than for direct currents. I have not, however, been able to verify this conclusion, owing to the difficulty experienced in measuring resistance accurately by means of alternating currents.

In my first paper I published the results of some attempts to find a relation between the effect of the different dielectrics upon the conductivity of the copper wire surrounded by them and their refractive index for light. In this attempt I was unsuccessful, but scarcely more so than have been the other attempts to establish a relation between the refractive index and the specific inductive capacity. Aside from the general discrepancy observed between the values of these two properties of dielectrics, it seems probable that neither Fresnel's nor MacCullagh's theory of the propagation of light in material bodies will give a complete explanation of the phenomenon, and that the refractive index of a substance will not alone enable one to judge of the elasticity or the density of the ether in that substance.

In a similar manner, if some dielectrics are absorbed more than others by the surface of a conductor, a mere knowledge of the specific inductive capacity of a dielectric will not enable one to foretell its effect upon the conductivity of a wire immersed in it.

I am aware that this hypothesis as to the nature of metallic conductivity leads to certain conclusions not experimentally established as to the nature of the field of force surrounding the current. If such oscillatory discharges as are here presumed take place between the molecules of a conductor, the entire field about the conductor would be filled with Herzian waves of very short period. Whether the magnetic field about a current can be accounted for on the assumption of the existence of these waves, I do not know. The velocity of the electro-magnetic induction could be satisfactorily explained in this way, and it is certain that very rapid ether vibrations of this kind can produce magnetic effects, but whether the magnetic polarity of the field may be accounted for by the greater intensity of the discharges in one direction than in the opposite. I do not know.

The Search Light in Coast Defence.

In the report of Brigadier General D. W. Flagler, Chief of the Bureau of Ordnance, just submitted to the Secretary of War, interesting reference is made to the use of the electric searchlight in coast defence, being the results of experiments made at Sandy Hook during the past summer. The lamp used in these experiments has a parabolic reflector with a diameter of 59.05 inches, and the total intensity of light claimed is 194,000,000 candle power. The focal distance of the parabolic mirror is 25.5 inches. The diameter of the illuminated area at a distance of 1,111 yards is 84 yards.

The light with the necessary accessories complete was installed at the Sandy Hook proving ground on a tower which places the light 100 feet above sea level. In carrying out the tests no difficulty was experienced in controlling the direction of the beam by an operator stationed at a distance from the light, by means of an electrical apparatus furnished. In the trials made to test its efficiency as a telegraph instrument, it was found that signals could be easily read at a distance of sixteen miles and probably considerably farther, but that they were invisible at forty-two miles. Trials were made to determine the effect of the color of the object, of the visibility of the fixed objects in known positions at different distances and of known moving objects; also for the detection by search of fixed and moving objects. These trials, while far from being complete, lead to this conclusion among others: that for efficient service the distance at which the light can be effectively used against boats seeking concealment is probably not greater than one and a half miles. Further trials will be made with the light placed at an elevation of about forty feet above sea level, as it is thought that the present elevation is too great to permit of the most efficient use of the light. Tests were also made as to the relative advantage of different positions of the observer with reference to the light. No satisfactory trial was had of the utility of the beam at different angles of dispersion of the rays. It is probable that the best use of the light in guarding areas such as torpedo fields would be in connection with the dispersing lens.

Electric Lights for Hindu Temples.

The *Times* of Ceylon states that it is in contemplation to introduce the electric light into the Sivan Hindu temple at Kochicadde, on the main road to Mutwal, Ceylon. The premises of the Hindu place of worship are at present lighted by gas. and the trustees propose to substitute the electric light for gas, a matter which is now under their consideration. It is said that if the Sivan Hindu temple introduce the innovation the trustees of the equally wealthy temple of the Natukotta in Sea street "are sure to follow the example set by their more enlightened brethren." There is no question that the coming "Light of Asia" is the electric light. The temple event is one that Siva, when Brahma and Vishnu were absent, would probably have termed Parbutta—auspicious.

CONCENTRIC WIRING.[*]

BY SAM. MAVOR.

It is a characteristic of the business of electric light wiring that it is peculiarly liable to the risks attending bad workmanship. Internal wiring is a comparatively simple matter. Apart from the distribution of lights and arranging the circuits and their routes, it is not work which must necessarily be done by a highly trained and skilled tradesman. On the contrary, any man who can use his hands may with very short experience, learn to joint wires and fix switches, and then call himself a wireman. The inevitable result is that such labor can, and always will, be cheaply purchased.

The business of electric light wiring has thus several features peculiar to it making for unreliable workmanship, which, in the absence of competent supervision and careful inspection, lead to defective work and resulting fire risk. The plumber's and the gasfitter's work is to a great extent self-testing. If a water pipe leaks we see the water, and if a gas pipe leaks we usually smell the gas; but we have no sense—no physiological sense—to enable us to find hidden defects in our electric wiring. A building may be wired in the most dangerously slipshod style, yet the lamps may for years burn none the less brightly, until the latent faults have opportunity to discover themselves.

Insulation tests after the completion of the work, if in dry and well-seasoned buildings, are of little value. The insulation tests of the wiring of an old building might show results three or four times higher than the most stringent rules require, and yet there might be a score of dangerous defects only awaiting opportunity to develop. No tests can be applied for the detection of these defects after the work is completed and covered in. When the prices of experienced contractors estimating for wiring work to a carefully drawn up specification vary, as we know they do, it is not strange that inexperienced contractors tendering in the absence of a specification, and without the prospect of any supervision, should quote prices which would not purchase suitable materials alone. These are matters of primary importance to the fire insurance companies, and they are much too lax in looking to their interests in this regard. Bad work is being carried out every day, and the insurance companies are complacently taking the risk.

There is a steadily growing dissatisfaction with the generally adopted practice of enclosing the conductors in wood casings, and a steadily growing conviction that something better might be done. When the usual double wiring is carried out in situations where moisture charged with acid from cemented or plastered walls of interiors, or in such buildings as paper mills, wet spinning mills, dye houses, breweries, distilleries, chemical works, and the like, the destruction of the insulation is only a matter of time, and the casing, by harboring the moisture around the conductors, hastens the process. After the insulation has broken down, electrolysis, assisted by the acidulated moisture, takes place, and deposits away the copper of one of the conductors, with the consequent risk of heating and ultimately of sparking. The presence of moisture being a necessary condition of the development of such faults, the dampness of the surroundings of the conductors greatly reduces the danger of fire, but that the risk is not absent is proved by the charred and burned casing or woodwork found at such places. It must be remembered, however, that heating due to diminished section of the conductor may occur at a time when the moisture which caused the fault has disappeared, and this is a danger which no amount of fuses will modify. How can you ensure that your wood-cased conductors shall never be subjected to such conditions? And how many of your average wireman's joints would stand 24 hours' immersion in water or soaking in moisture? The miserably futile expedient of attempting to waterproof the casings with putty and varnish is sometimes resorted to; such makeshifts are too childish.

Lead-covered conductors are occasionally used where much moisture has to be encountered. But these for double wiring are a mistake, unless the positive and negative wires are both enclosed in the same lead sheathing. The objection to separate lead-covered conductors is that, if there should be an earth or leak on the negative wire, and the lead and insulation of the positive wire become punctured at a damp situation, the lead becomes charged positively, and will be deposited away over its whole length where moisture is present to assist electrolysis.

After wood casing, with its perviousness to moisture and other attendant disadvantages, the biggest blot on existing practice is the indiscriminate use of fuses. Some insurance people, and wiring contractors too, imagine that the risk of fire varies inversely as the number of fuses. The contrary is more near the truth. Fuses are not only a nuisance, they are apt to be a positive source of danger. The smaller number of fuses used the better; but they must be absolutely reliable, well mounted, and well placed.

It is with a sense of relief that one turns from double wiring and all its attendant ills to the simple mechanical and straightforward methods of concentric wiring with an uninsulated outer conductor. So far as the writer is aware, no system of concentric wiring in which both the inner and outer conductors are insulated has ever been used for indoor work. It appears probable that the difficulties in the way of designing junctions, switches, and other accessories which shall meet the electrical and mechanical requirements within moderate dimensions and at reasonable cost, will prevent the introduction of such a system. Two and three wire concentric cables with each conductor insulated are largely used as mains in connection with two and three wire systems, but in such cases there is no difficulty in providing junction boxes of adequate size. The only system of concentric wiring which has been adopted for internal use has an uninsulated outer conductor, and it is this system that is known as "Concentric Wiring." It is important that it be clearly understood that concentric wiring is not "single wiring," but is something essentially different. This distinction between concentric wiring and single wiring is necessary, because the two have been frequently confused. No method of wiring merits the title "concentric" which is not consistently concentric throughout. In a concentric system the central conductor must be everywhere surrounded over its insulation by a metallic sheathing of conductivity equal to or greater than the core. The switches and fuses should be in the central wire and enclosed in metal cases. These cases or boxes should be electrically and mechanically jointed to the outer conductor and so form part of the continuous metallic envelope in which the central conductor is enclosed.

It has been stated that, owing to one conductor being already earthed, the liability to complete breakdown of the insulation is doubled. This might be true of double wiring, but is certainly not true of concentric. The outer conductor being already at earth potential, there cannot be any risk whatever of shock or spark being experienced from it. There is thus only one vulnerable conductor, and this, with its insulation being encased throughout its entire length in the metallic sheathing formed by the outer conductor, is well protected against injury. The consequences of injury to concentric and to double wiring are essentially different. In the case of the concentric conductor, if it should be crushed or a nail be driven into it, the instantaneous result is a dead-short circuit and the melting of the fuse. If the insulation should be punctured and moisture gain access, the distance across the insulation between the conductors is so small that the fault immediately develops into a short circuit, and the spark passes from the center conductor to the inner surface of the metallic sheathing, and being entirely within the sheathing it cannot communicate fire to its surroundings. Concentric conductors are thus self-testing. Faults cannot endure. They cut themselves out automatically. Or, rather, this is what they would do if faults were experienced, but we never have faults in lead-covered concentric conductors. In concentric wiring there is only one cable to handle instead of two, and this carrying its own protection the necessity for wood casing is abolished.

Perhaps the most conspicuous advantage of concentric wiring is that it may be so easily and so effectually made waterproof. The cables may be enclosed in lead sheathing laid under or over the outer conductor, and hermetically sealed to the various apparatus into which the cables are led. This must appeal to all those who have had a varied experience of wiring.

The next important advantage to be claimed is the large reduction in the number of fuses. The drastic method of abolishing fuses is to maintain the section of the conductors. This can readily be done in concentric wiring to an extent impracticable in double wiring. Conductors of much larger section may be conveniently and safely led into lamp-holders, ceiling roses, and wall sockets, than is possible in double wiring. And thus, by maintaining the section of conductors right into the lamp-holders, many of the objectionable fuses are abolished.

The more difficult the wiring of a building appears to be, the more favorable is the comparison to concentric wiring. The iron roofs, concrete floors, moisture, and other ills that vex the spirit of the double wirer, have no terrors for his concentric friend. For wiring in any situation, from collieries to boudoirs, where difficulties of erection have to be faced, or in situations where the conductors, etc., after erection must endure excessive heat or cold, moisture, acid vapor, or inflammable dust, concentric wiring meets the case. Concentric wiring has this further advantage—that a very simple and easily followed set of rules can be framed which are applicable to wiring to be carried out under widely differing conditions.

For mining work concentric wiring is specially adapted. The mechanical nature of the fittings and the ease with which they and the conductors may be made waterproof are important features. A concentric cable for mining purposes is more safe than two separate cables. A fall of material from the roof may rupture one or two conductors, and if current is passing the inevitable result is a spark at the point of parting. In fiery mines this may have serious consequences. With a concentric conductor, however, the fall would crush the outer conductor in upon the core, and so cause a dead short-circuit and melt the fuse before the cable parted. The spark would thus take place at the fuse at the pit bank.

With regard to the wiring of ships, it is well known that an essential condition of durable wiring is that it shall be water-proof throughout. The Admiralty still adhere to double wiring owing to fancied danger of compass disturbance from concentric wiring. That well-arranged concentric wiring has no effect whatever upon the compasses of a ship has been proved by the most careful tests. The waterproof qualities of concentric wiring and the safety from fire which it ensures peculiarly adapt it for use on board ship.

And now with regard to possible electrolysis due to difference of potential along the outer conductor. In isolated installations where the distances are short the question of electrolysis may be dismissed as having no bearing. In cases where the distances are considerable the risk of electrolysis may be entirely avoided by adopting very simple precautions. The first of these is to so proportion the conductivities of the inner and outer conductors that the fall in volts shall be nearly all in the inner conductor; the copper

---

[*] Abstract of Paper read before the London Institution of Electrical Engineers, November, 1895.

saved from the inner conductor being added to the outer in order to reduce to a minimum the difference of potential between its ends. Another method adopted by the writer is to provide between the outer conductor and its lead sheathing a very light insulation, and to earth the outer conductor only at the distant end.

In dealing with distribution for electric lighting purposes we do not have to contend with such large differences of potential at different points of the system, and the difficulties are not at all comparable with those encountered in street car work. A three-wire system with the middle earthed, and concentric wiring on each side with the sheathings connected to the middle wire, is an ideally safe and reliable system of distribution. In a well-balanced three-wire system the fall of volts along the middle wire is negligible, and there is therefore no danger of electrolysis. No disturbance to telephones could take place. Stray currents passing between faults in the conductors would be impossible. The positive and negative conductors being each surrounded by an earthed sheathing, no current can escape from them. Leaks in concentric cables will not endure. The distance between the inner conductor and its sheathing being only the thickness of the insulation, a fault develops at once into a short-circuit which is internal to the sheathing of the cable, and the fuse at once comes into operation. But it must be repeated that faults are much less liable to occur in concentric cables than in double wiring. The importance and safety of the self-testing properties of concentric wiring must be obvious.

BOOK REVIEWS.

Electrical Engineering Leaflets. By Professor E. J. Houston, Ph. D., and Professor A. E. Kennelly, F. R. A. S. Three volumes: Elementary Grade, Intermediate Grade and Advanced Grade. Each 280 pages, 8vo., at $2.00. New York: *The Electrical Engineer*.

The preface indicates the scope of these works so well that we quote it in full:

> The Electrical Engineering Leaflets have been prepared for the purpose of presenting, concisely but accurately, some of the fundamental principles of electrical science as employed in engineering practice. They have been arranged under three grades: namely, the Elementary, the Intermediate, and the Advanced.
>
> The Elementary Grade is intended for those electrical artisans, linemen, motormen, central station workmen, or electrical mechanics generally, who may not have advanced sufficiently far in their studies to warrant their undertaking the other grades. Here the mathematical treatment is limited to arithmetic, and the principles are illustrated by examples taken from actual practice.
>
> The Intermediate Grade is intended for students of electricity in high schools and colleges. In this grade a certain knowledge of the subjects of electricity and physics generally is assumed, and a fuller mathematical treatment is adopted. These leaflets, moreover, contain such information cencerning the science of electricity as should be acquired by those desiring general mental culture.
>
> The Advanced Grade is designed for students taking special courses in electrical engineering in colleges or universities. Here the treatment is more condensed and mathematical than in the other grades.
>
> Although the three grades have been especially prepared for the particular classes of students referred to, yet it is believed that they will all prove of value to the general reading public, as offering a ready means for acquiring that knowledge which the present extended use and rapidly increasing commercial employment of electricity necessitates.

These leaflets were originally issued by numbers from the press of the *Electrical Engineer*, and in that form proved so popular among electrical students as to cause them to be put in more permanent form in binding. The language is simple and direct and well adapted to the wants of the several grades of students for which they are intended. The reputation of the authors is such as to inspire confidence that the statements are rigidly accurate, and in most cases we find them so.

One or two minor lapses are, however, noticed. One of these will be found on pages 58 and 59 of the Intermediate Grade, where the "Municipal" series system is wrongly described and wrongly illustrated in diagram. As given, it is a simple straight series arrangement, whereas the "Municipal" series was a multiple series arrangement.

The most serious defect of this otherwise admirable treatise is the incorporation of many technical terms originated by the authors themselves and not in general use. Without attempting at this time to discuss the value of this new coinage, we think there can be no question as to the impropriety of the attempt to force these unused terms upon the readers or students of the books.

Modern Examinations of Steam Engineering, or Practical Theory Explained and Illustrated. By W. H. Wakeman. Cloth, 8vo. 272 pages. Bridgeport, Conn.: American Industrial Publishing Company.

The long-continued and well-directed efforts of the author for the elevation of the position of the practical engineer will certainly meet with substantial reward when the scope and character of this work become fully known. While the book is essentially a manual intended "to give information to those engineers who wish to qualify themselves to pass examinations and take out licenses to run stationary engines in those localities where such examinations are required," it is valuable as a text book for all those wishing to become better informed about the construction, operation and care of steam engines. There is almost an entire absence of abstruse mathematical data, the treatment of all subjects being plain and practical, so as to be readily understood.

This little volume will very materially assist any energetic fireman or engineer who desires to become more proficient in his work, as well as to become more valuable to his employer, to gain an accurate and comprehensive knowledge of the practical theory of the steam engine and its accessories.

SOCIETY NEWS.

American Institute of Electrical Engineers.

By direction of the Committee on Papers, Meetings and Editing, the meeting of the American Institute of Electrical Engineers scheduled for December 18 will be omitted. Due notice will be given as usual of the January meeting. Members are requested to notify the secretary at once of any recent change in address, as a new catalogue is in preparation to be printed in the December issue and also incorporated in the bound volume of 1895.

The Chicago Electrical Association.

The first meeting of the Chicago Electrical Association, held on the 6th inst., was well attended. The meeting was devoted to a discussion of the outlook for junior electrical societies, or societies composed wholly of young men who are anxious to exchange information on electrical topics. The paper of the meeting was entitled "Our Electrical Association," read by Albert Scheible, manager for George Cutter, Chicago.

The topics and leaders for subsequent meetings are as follows:

December 20—"What Next in Electric Railway Work?" J. B. Cravath, Electrical Editor *Street Railway Review*.

January 3—"The Protection of an Invention." W. Clyde Jones, with Barton & Brown, Patent attorneys.

January 17—"Armature Windings for Multipolar Generators." F. A. Muschenheim, designer for Western Electric Company.

February 6—"Lightning Arresters." W. R. Garton, manager Electric Railway Department, Central Electric Company.

February 20—"The Outlook for Electrochemistry. Bertrand S. Summers, chemist Western Electric Company.

GENERAL NEWS.

What is Going On in the Electrical World.

Dardanelle, Ark.—An electric light plant is soon to be added to the improvements now under way in this town.

Bluefield, W. Va.—Contracts are being let for the construction of an electric railway between Bluefield and Graham.

Salem, O.—The Salem Electric Light & Power Company and the Salem Electric Railway Company have been consolidated.

Rome, Ga.—The Rome electric light plant has been sold for non-payment of taxes, and was bid in by Capt. N. H. Bass for $3,000.

Caseville, Mich.—The Caseville Electric Lighting Company has been organized to put in a plant to furnish public and private lighting in this town.

Sharon Hill, Pa.—The council has passed to a third reading an ordinance relating to the issuing of a contract for lighting the village with electricity.

Utica, N. Y.—The common council has appointed a special committee to inquire into the feasibility of the city's owning and operating an electric light plant.

San Bernardino, Cal.—The Santa Fe Railroad Company is planning to have the street car line connecting with its depot run by electricity instead of horse power.

Bath, N. Y.—The management of the Bath & Hammondsport Railway Company are reported to be considering the advisability of substituting electricity for steam.

Hampton, Va.—A survey is being made for a new electric railroad from Hampton to Buckroe, on Chesapeake Bay, where it is proposed to put up a large summer hotel.

Pensacola, Fla.—An ordinance granting Sterritt Tate and his assigns a franchise for an electric street railway in this city has been referred by the council to the city attorney.

Bowdle, S. D.—A company, composed of Clark Hudson, W. W. Brant and the Bowdle Milling Company, has been formed for the purpose of putting in a system of electric lights in this city.

Greenville, N. C.—The proposition of the Greenville Lumber Company to put in an electric light-plant if the town would rent light for the streets has been accepted by the town council.

Nacogdoches, Tex.—R. C. Shindler, the founder of the electric light plant which has just been put in operation here, was honored by a musical serenade on the night of the opening.

Holyoke, Mass.—The Connecticut River Manufacturing Company has ordered an electric plant for 500 lights, arc and incandescent, from the Westinghouse Company's Boston branch.

St. Johnsbury, Vt.—F. C. Kennedy and J. S. Pierson, of Burlington, have been visiting St. Johnsbury in the interest of the proposed electric street railroad and found the people enthusiastic in its favor.

Portland, Ore.—As soon as the city council grants the Portland Traction Company the necessary permission to change the power used in operating its cable road, the work of electrifying the line will be commenced.

Canton, O.—The county commissioners are considering the advisability of putting in an electric light plant at the workhouse, for the purpose of furnishing that institution, the court house and the county jail with light.

Ladonia, Tex.—A stock company, capitalized at $10,000, has been organized here to put in an electric light system. The stockholders are T. V. Richards, J. W. Nail, D. E. Wagoner and J. A. Jackson, all of Ladonia.

Port Jervis, N. Y.—The board of trustees have set January 6 for a hearing relative to the application of the Port Jervis Electric Street Railway Company for a franchise to run electric cars in certain streets of this village.

Whitestone, L. I., N. Y.—Water Commissioner Joyce has a scheme to put in and operate an electric lighting plant in connection with the local water works which will probably be adopted. The present gas lighting contract expires December 31.

Princeton, Ind.—The Princeton Interurban Electric Railway Company, composed of St. Louis, Chicago, Louisville and local capitalists, propose to establish an electrical street railway system in this city, and have applied to the council for a twenty-year franchise.

Leadville, Col.—The Citizens' and the Leadville electric light companies have consolidated, and there is now but one electric light company in this city. The stock of the new company, $150,000, has been divided equally between the holders of the old companies.

Newark, N. J.—The People's Electric Light and Power Company of Newark, which recently secured control of the Newark Electric Light and Power Company has acquired a controlling interest in the Essex County Electric Light and Power Company of Orange.

Elizabeth, N. J.—The Mutual Investment Company is the name of a concern recently organized here for the purpose of placing electric light plants, railways, etc., in Mexico and Central America. John W. Rehill, William F. Stryker and James P. Powers are the promoters.

Kingston, N. Y.—The Colonial Electric Street Railway, which has been in the hands of receivers, has been sold at judicial sale by the referee, John F. Cloonan, for $70,000 to Charles Stewart Davidson, of New York City, who represented a committee of the first-mortgage bondholders.

Bennington, Vt.—The Bennington and Woodford Electric Railway Company has decided to expend $20,000 in extending the line from Camp Comfort in Woodford to "the forks" of the Roaring Branch in Glastenbury, four miles and a half, and in fitting buildings for a summer resort.

Alameda, Cal.—The Alameda city electric light plant is to be increased by the first of the new year by the addition of a 350 horse-power engine and three boilers and dynamos sufficient to give 3,500 additional incandescent lights besides the 1,200 now in use. A few more arc lights will also be added.

New Castle, Col.—The town board recently passed a resolution declaring the need of an electric light plant. Samuel Wraith is chairman of the committee to secure information as to cost. A thousand lights will be used. In the event of satisfactory bids not being offered the town will put in its own plant.

Greensburg, Pa.—A new electric car line is projected here by Hugh Keogh, a contractor of Lancaster; Samuel A. Miller and Edward Saxman, of Latrobe, and some Pittsburg capitalists. It will be run from Derry to Latrobe, touching Youngstown, Whitney, Lippincott furnaces and St. Xavier Academy.

Sunderland, Mass.—The Worcester Construction Company has given an estimate of $75,000 as the cost of building an electric road from Mill Valley to Sunderland. A meeting of those interested in the proposed road has been held, at which a committee, consisting of H. M. McCloud, W. D. Cowles, and H. L. Ufford, was elected to solicit subscriptions.

Sherman, Tex.—It is stated that a prominent syndicate in Ohio is making investigations as to the feasibility of building an electric line between Sherman and Denison, and it is known the right of way can be easily secured. The population of the two cities and a quarter of a mile of territory each way from said proposed line will approximate 35,000.

St. Paul, Minn.—The committee on transportation of the Chamber of Commerce has been directed by that body to inquire into the desirability and practicability of a rapid transit electric line between St. Paul and Minneapolis that shall make few stops, and shall run from the center of one city to the center of the other in not more than thirty minutes.

Ipswich, Mass.—There is a good prospect of an electric road being built before many months that will connect Ipswich with Gloucester and Beverly by the way of Essex. A hearing before the citizens of Ipswich on the petition of the Gloucester, Essex & Beverly Street Railway Company to lay tracks from Essex to the center of Ipswich will be held in the town hall December 27.

Omaha, Neb.—During the past year there have been no fires here traced to electric wires, and in the opinion of the councilmen and others who have taken an interest in the matter a great deal of credit should be given to the present city electrician, Mr. Schurig, who has insisted that all new work put in shall comply strictly with the law and has caused a great deal of defective wiring to be removed.

Edgartown, Mass.—The Martha's Vineyard Street Railway Company, recently incorporated, will petition the next Legislature for authority to build and operate an electric road uniting Edgartown, Cottage City and Tisbury. The promoters of the company are John R. Graham, John A. Dugann, Fred H. Smith, Josiah Quincy, Fred Nichols, William A. Gallivan, John F. Merrill and others.

Washington, D. C.—One of the stockholders of the new Columbia and Maryland Railway expresses the belief that "this line is the American pioneer of electric trunk-line railroads. It is the nucleus of a great system which will connect New York and New Orleans." The primary purpose of the company named is to build an electric road from Baltimore to Washington. Thomas M. Lanahan, of Baltimore, is president.

Hackettstown, N. J.—Surveys are being made for the route of a proposed new trolley line to connect Valley, on the Lehigh Valley Railroad, with Lake Hopatcong. This road will be built by the Lehigh Valley Railroad as a competitor of the New Jersey Central's branch, which connects with the main line at High Bridge. The road will be about twenty-five miles long, and will run through Washington and Hackettstown. The right of way for nearly the whole course has been secured.

Lowell, Mich.—The common council has appointed a committee to ascertain the probable cost of the construction and equipment of an electric plant for light and power. The committee, it is thought, will report it less than $23,000, which is within the bonding power of the city.—The Lowell Water & Light Company have nearly completed their transmission plant and will soon be able to furnish electric light and power for Grand Rapids.

Anderson, Ind.—The bids for the construction of the Gas Belt Electric Railway were opened on the 8th inst. It is specified that work on the road must begin the first of the year. The route, when completed, will include Indianapolis, Anderson, Muncie, Marion, Elwood, Alexander and other gas belt cities. The equipment will be adapted to freight and express traffic. Congressman Henry, of Anderson, is one of the chief promoters of the road.

Detroit, Mich.—Mayor Pingree, who has been conducting a red-hot campaign against the Citizens' Railroad Company because it has failed to fulfil its promises of a reduced car fare, was put off a car of the company a few days ago on his refusal to pay the full fare. The conductor who performed the feat was a black man and the mayor offered little or no resistance. His friends say he didn't care to carry the war into Africa.

South Bend, Ind.—The court has approved the sale of the South Bend & Mishawaka electric railroad to George E. Clifford, president of the Wachusett National Bank, of Fitchburg, Mass. The road includes the electric railroad system of South Bend and the four-mile road running up to Mishawaka on both sides of the St. Joseph river. The price paid was $50,000. Mr. Clifford intends to add materially to the equipment of the road and improve it in every respect.

Jersey City, N. J.—The People's Electric Light and Power Company of Newark has been awarded the contract for the electrical portion of the city lighting. The bid of the company was $90 per annum for each of the 340 arc lights.—The street railway system of the Consolidated Traction Company is about completed. The road from Jersey City to Bloomfield on the north, Elizabeth on the south and the Oranges on the west, measures about 175 miles in all.

Tacoma, Wash.—H. L. Thomas, of Seattle, intends to apply at once to the council for a franchise for a double-track broad gauge electric railroad across the bridge and to the city limits towards Seattle. Application has been made for a similar franchise in Seattle. Mr. Thomas said that a strong company was being organized to build a double-track electric road between Tacoma and Seattle. The line will be called the Seattle, Tacoma & Portland Electric Railway, the company desiring to ultimately complete it to Portland.

Taunton, Mass.—The Fall River and Taunton Street Railway Company has petitioned for an amendment to its charter which will extend its rights as a corporation to July 1, 1903, and which will permit it to build and operate a street railway between New Bedford, Freetown, Acushnet, Berkley and Taunton. Wm. M. Butler is president of the company, and among the railway men interested are Abbott P. Smith, Charles E. Cook and E. P. Shaw of Boston, and Major Pond of New Haven.

Kansas City, Mo.—The plant, property and good will of the Franklin Electric Company of this city has been sold to Hodge, Walsh & Loring, who will conduct the business at the old stand. R. W. Hodge, the head of the firm, is the son of R. H. Hodge, president of a bank at Brunswick, Mo., and is himself a graduate of the electrical engineering department of the University of Missouri; J. E. Walsh has been connected with W. T. Osborne in practical electrical work, and H. L. Loring has had charge of the Franklin Company's construction work for four years.

Philadelphia.—Proposals for furnishing electric lights for the city next year will be received until December 23, on which day the bids will be opened. There are at present 6,228 electric lights paid for by the city, eighty-three furnished for street lighting free by the companies and fifty paid for by the Girard estate. In the estimates furnished the Finance Committee a short time ago there was an item of $50,000 for new lights for next year. It has been intimated that this will not be allowed, and that the regular appropriation for lighting the city will be cut down.

Orange, N. J.—A story is current here that Thomas Nevins, a railroad contractor of this town, has purchased Killeen Castle, in County Meath, Ireland, and has secured a contract to build trolley lines in that part of the county in which his newly acquired property lies. In consideration of the franchise granted to him Mr. Nevins agreed to carry people free for a year, and to give a bond of $100,000 that he would faithfully carry out his contract. It may be proper to add that the offer was made and accepted at a banquet at which Mr. Nevins and members of the town corporation were guests.

Chicago.—Richard E. Sherman, an electrician of this city, has invented and patented a new underground trolley system which, he asserts, will soon be in operation on one of Mr. Yerkes's roads. He says Mr. Yerkes has examined the working model and pronounced it the most practical he has seen in his experience, and has promised to give it a trial.—Referring to the best methods of rapid transit, the statement is made that during the terrific storm of November 25 in this city, the Metropolitan Elevated Railway, which is operated by electricity, experienced practically no delays, while all the other roads were blocked for hours.

New York.—The White Locomotive Works intends to erect a large plant near this city for the manufacture of a new freight locomotive, the invention of Walter W. Scott, of Buffalo, which can be adapted for electrical driving power. Tests of the new machine are said to have shown that it effects a saving of 25 per cent. in fuel and can haul 25 per cent more freight than the ordinary locomotive.—The Manhattan Athletic Club has purchased its club house for a sum stated to be $500,000. The building is to be immediately supplied with a new electric light plant.—The Edison Electric Illuminating Company of New York reports for November: Gross earnings, $179,599; increase, $6,755. Net earnings, $90,755; decrease, $1,739. From January 1 to November 30: Gross earnings, $1,658,976; increase, $165,691. Net earnings, $799,189; increase, $82. 746.

Boston, Mass.—The Brookline Street Railway Company is to be entirely equipped by the Electric Storage Battery Company of Philadelphia. The cars will be 22 feet long and will, it is said, be the most beautiful upon any street railway in America. It is proposed to electrically run, light and heat them by storage batteries. The agreement stipulates that the Storage Battery Company shall operate the road by means of its storage battery system for at least six months to the satisfaction of the owners of the road, and the storage battery people are so confident of the success of their system, which is the same as that now in use upon the Madison and Fourth avenue line in New York, that they will put up a forfeit large enough to cover all costs of the equipment should it prove a failure.

Cincinnati, O.—Mr. Fred Pentlarge, who was appointed a committee by the Board of Transportation to make investigations relative to underground conduits for electric railways, reports that he has been assured by F. Harschitz, M. E., of Vienna and Budapest that he will come to Cincinnati, if his expenses are guaranteed, and undertake the building of an underground conduit electric road that can be operated successfully. Mr. Harschitz built the underground conduit road at Budapest which has been in operation since 1892. The report of Mr. Pentlarge was strongly in favor of the underground conduit system for street railways in this city, and it was approved by the Board of Transportation, who earnestly commended it to the consideration of the street railroad companies, the Board of Administration and the public.

TELEPHONE AND TELEGRAPH.

More Suits by the Bell Company.

The Western Electric Company has brought suit in the United States Circuit Court at Sacramento, Cal., against the Capital Telephone and Telegraph Company of that city for alleged infringement of Leroy B. Firman's patent No. 252,576, dated January 17, 1882, on multiple switchboards, and on the Watson telephone switch patent No. 270,522, of January 9, 1883.

The instruments, 700 in number, used in the exchange of the Capital Company were manufactured and sold by the Columbia Telephone Manufacturing Company, 136 Front street, New York.

The Capital Company, through its attorney, L. T. Hatfield, has filed answer to the bills of complaint in the suits. The answer is a denial of all the specifications in the complaint.

Telephone Conversation as Evidence.

O. A. Cole, an electrician of Stevens Point, Wis., has been subpœnaed as a witness in the famous Stillwell murder case soon to be tried at Bowling Green, Pike County, Mo. When the murder occurred at Hannibal, Mo., December 29, 1888, Cole was connected with the telephone exchange in that city. On the Sunday before the murder Cole was at the switchboard and overheard a conversation between the suspects of the crime, which he leisurely jotted down, thinking probably it would some day be needed. This testimony has never been given to the public and will prove an important factor in the solution of the mystery.

Activity in Western Pennsylvania.

The "Courier," Connellsville, Pa., states that a comprehensive independent telephone system is in course of construction in the southwestern section of that State. The Somerfield Telephone Company, of which Dr. T. J. Jacobs of Somerfield is the leading spirit, is completing a line from Somerfield eastward to the Maryland line. At this point connection will be made with a line now in contemplation from Grantsville and Accident, in Preston County, W. Va. A line is now in operation between Grantsville and Oakland, the county seat of Preston County.

From Somerfield westward, the Somerfield company's line extends to the West Virginia line. Stations will be established at Addison, Somerfield, Jockey Hollow, and Markleysburg, Pa. At the West Virginia line, connection will be made with the Kingwood & Brandonville Telephone Company's line. The Kingwood line will furnish connection with Brandonville, Glade Farms, Kingwood, and thence with Tunnelton, Terra Alta, W. Va., and Oakland, Md. When the line between Grantsville and the Somerfield company's lines is built, which will probably be in the spring, the circuit will be complete. It will include the principal towns in southern Somerset and Fayette Counties, Pa., Preston County, W. Va., and Garrett County, Md.

The Connellsville coke region will eventually be connected with this circuit. There is now a line from Uniontown to Farmington. This line will probably be extended to Brandonville. If it is not, the Somerfield company will extend their line to Farmington in the spring. This will give them a connection with the coke region circuit and with Pittsburg, also with the new line just completed to Morgantown and Fairmount, W. Va.

The Pacific Cable.

The Pacific Cable Company has been incorporated at Albany, N. Y., with a capital of $100,000. The directors are Edmund L. Baylies, H. L. Leroy, C. D. Wetmore, G. A. Mills, Montclair, N. J.; J. M. Robertson and W. H. F. Hughes, of New York, and F. H. Allen, Pelham Manor, N. Y.

Mr. Edmund L. Baylies, has stated that the company would eventually increase its capital stock to $8,500,000 or $10,000,000, and that it intended to proceed with the laying of the cable as soon as the preliminary arrangements had been concluded. The plan contemplates a cable from San Francisco to Hawaii, and thence to Japan and other points on the coast of Asia, with a branch to Australia. The business between New York and San Francisco will be done over leased wires. Steps have been taken to secure the concessions necessary for landing the cable in Hawaii and Japan.

Senator Mitchell, of Oregon, has introduced a bill in the Senate which asks for an appropriation, not to exceed $50,000, to be used for the purpose of constructing a military and commercial telegraphic line along the Pacific coast between Yaquina, on Yaquina Bay, and Port Orford, to connect with Newport, on Yaquina Bay; Alsea Bay; Florence, on Sinslaw Bay; Gardiner, on the Umpqua river; Empire City and Mansfield, on Coos Bay in the State of Oregon.

B. G. Greene, Z. C. Brewster, Willoughby & Fletcher, Carl & Cronk, Thomas W. Robinson, John J. Lillis, Millard D. McNeil, Dr. E. M. Casey, Frederick Rorapaugh, Frank E. Beadle, A. P. Hyde Machinery Agency, Clark L. Webb, F. H. Hendrickson, Charles W. Sherwood and the New York, Ontario & Western Railroad are the parties comprising a co-operative company which has been organized at Oxford, N. Y., to construct a telephone system to connect the New York, Ontario & Western Railroad station, one mile east of the village, with a number of the stores and other business places in town.

The temporary injunction restraining the Wisconsin Telephone Company from erecting poles in the streets of Sheboygan has been continued, thus deciding a case that is of general interest all over the State of Wisconsin. The company is not restrained from operating its telephone line as it exists now, but is prohibited from erecting poles to extend its lines.

At the recent annual meeting of the stockholders and directors of the North American Telegraph Company held at Minneapolis, Minn., the usual semi-annual dividend of three per cent. was declared, after which the old directors and officers were re-elected. The title of H. A. Tuttle was changed from that of general superintendent to general manager.

Mrs. Sarah Lewis, of Sioux City, Ia., who brought suit against the Home Telephone Company of that city for $7.000 damages for injuries sustained by falling head first into a telephone pole hole, has agreed to a settlement upon the payment of $800.

The directors of the American Bell Telephone Company have just declared a regular quarterly dividend of 3 per cent. and 1½ per cent. extra. This makes a total of 15 per cent. declared this year, 12 per cent. regular dividend and 3 per cent. extra, 1½ per cent. being declared June 12.

The directors of the Western Union Telegraph Company have declared a quarterly dividend of 1¼ per cent.

William Blake of Cheboygan, Mich., will build a telephone line between that place and Petoskey, taking in the villages of Millet Lake, Topinabee, Indian River and possibly Wolverine.

The Buffalo "News" says that the poor service of the Bell Company in that city is "driving the patrons crazy."

During the fiscal year just ended there have been 31 telephone and telegraph companies chartered in Ohio with an aggregate capital of $780,500.

N. H. Egleston, Jr., has asked for the right to establish a call and messenger service in Augusta, Ga.

A new telephone system is being constructed in Dover, Del.

The Home Telephone Company of Jersey City, N. J., has applied to the street and water board for permission to lay conduits and erect pole lines.

By order of the court, the Independence Telephone Company's exchange and toll lines at Independence, Kan., will be sold at public sale, December 19.

W. W. Rider, formerly manager of the Mutual District Telegraph Company, New York, has been appointed manager of the Central Union Telephone Company at Indianapolis, Ind.

The board of police commissioners of Albany, N. Y., is considering the advisability of equipping the second police precinct of that city with a signal service.

The United Telegraph, Telephone and Electric Company expects to have its new exchange in Hyde Park, Chicago, in operation by January 15 next.

By the completion of 130 miles of line La Crosse, Wis., has been added to the exchanges of the Northwestern Telephone Company.

E. J. Foote has leased the Luray & Sperryville Telephone Company's lines, connecting Luray and Sperryville, Va.

The toll lines of the new telephone at Wausau, Wis., are to be extended to Grand Rapids, Wis., via Marshfield.

New Companies Incorporated.

The Simplex Telephone Company, of Cincinnati, O., has increased its capital stock from $5,000 to $6,000.

The Rochester Telephone Company, Rochester, Ind., has been incorporated with a capital stock of $10,000. It will operate telephones in the counties of Fulton, Marshall, Wabash, Kosciusko, Pulaski, Starke, Cass and Miami.

The Farmington Telephone Company, Farmington, Ia. Capital stock, $1,000. The incorporators are G. R. Neff, president; W. H. Thero, vice-president, and C. L. Paisley, secretary and treasurer.

A. M. Temple, R. J. Pratt, David Caulkins, J. N. Davis and others of Kansas City, Mo., have incorporated the Kansas City Telephone Exchange, with a capital stock of $200,000, to manufacture telephone instruments, etc.

"The Card" Multipolar Series Reversible Mill Motor.

For operating heavy machinery in rolling mills, foundries, and particularly for swing bridges and traveling cranes—in fact all places where a strong, simple and serviceable machine is required, no power can be more adaptable than the electric motor.

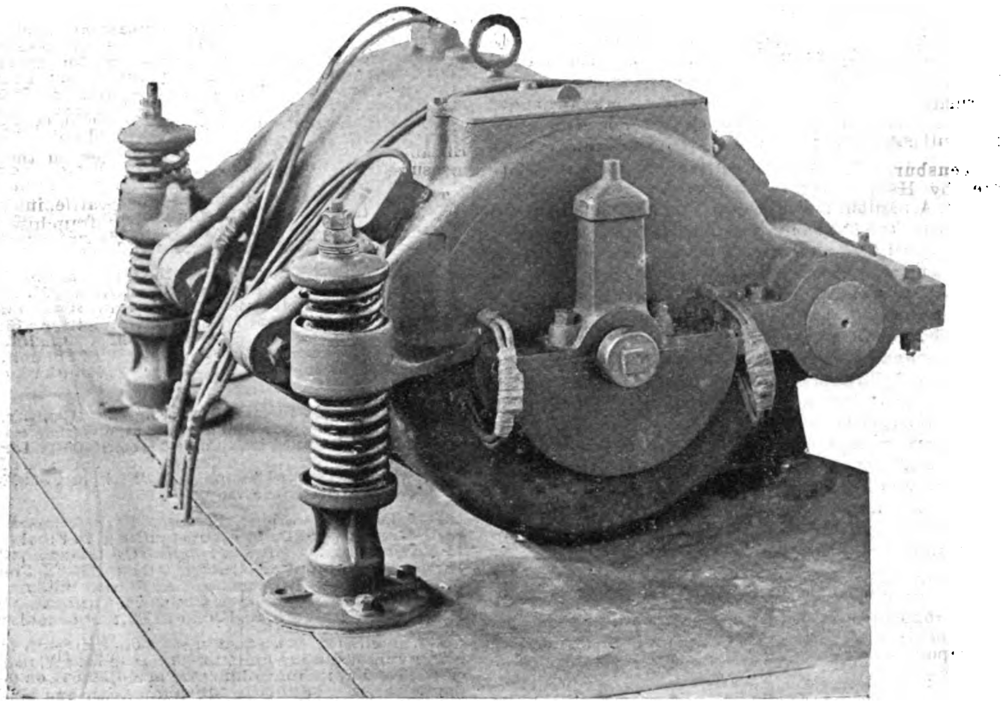

Fig. 1.—"Card" Mill Motor.

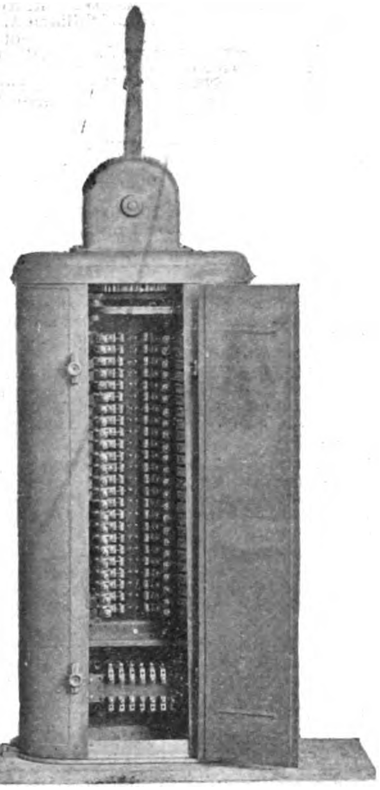

Fig. 2.—"Card" Controller.

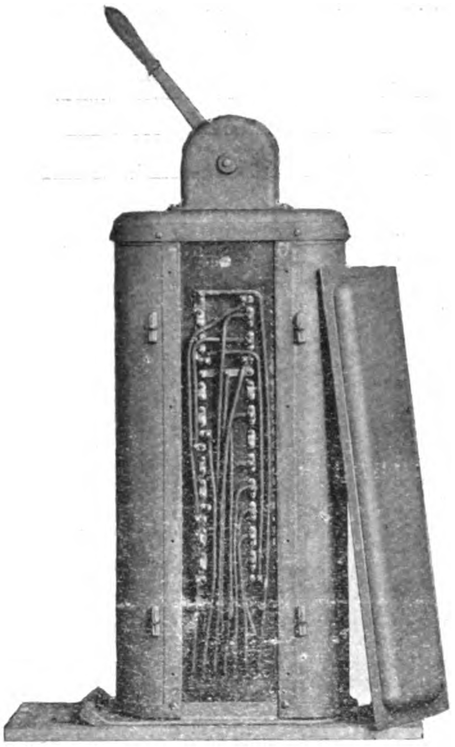

Fig. 3.—"Card" Controller.

The accompanying cuts, Figs. 1, 2 and 3, show "The Card" Series Reversible Multipolar Motor and Controller manufactured by the Card Electric Company, Mansfield, Ohio.

Fig. 1 shows the motor completely enclosed and can be used in places where the open type of motor would soon be destroyed. This motor, in connection with the improved controller and current regulator, makes a very desirable outfit for operating traveling cranes, turn bridges, hoists, bending rolls and other kinds of machinery which require various speeds in either direction. Attention is called to the method of mounting this motor for general work. The front of the motor is supported on a cast iron stand rigidly fastened to the bed-plate of the machine or other foundation, with trunnions on each side of the upper part taken through suitable bearings on the motor case, forming a pivot for the motor to swing on. The rear part of the motor is supported on springs at each side, with springs above, held in compression by bolts through the pedestals which support them and which are also fastened to the bed-plate. The object of this arrangement is to provide a flexible support for the motor and a cushion for the gearing when heavy loads are thrown on the motor or the direction of rotation is suddenly reversed. In practice it has been found to work admirably, and, in addition to saving the gears, gives the motor a noticeable advantage in starting heavy loads at slow speed. Where the conditions are such that the spring suspension is not advisable, brackets are provided on the motor for bolting to the bed-plate or foundation, rigidly.

To satisfy the class of work for which this motor is designed, nothing but the best material can be used with safety and the construction must be as thorough and complete as it is possible, with modern machine tools, to make it. Special pains have been taken in the design to provide large bearings for the armature shaft and other parts subjected to strains and wear, and allow in every part a generous excess of metal for mechanical strength and as a factor of safety electrically.

Fig. 2 shows the controller with the lever in a vertical position for current "off" and the door open, exposing the mechanism for regulating the current.

Fig. 3 shows the back removed, exposing the wiring and connections to contact fingers.

The controller is strongly put together and finished with iron filter or japan as desired. The working parts have received the most careful attention. They are practically self-contained, and with the exception of the operating lever are fastened to a back made in one piece which can be removed from one case to another without disturbing any of the parts.

Each controller is provided with two revolving cylinders, geared together and operated by the lever at the top, on which are fastened a series of contact rings. The one at the right is used exclusively for opening and closing the circuit and has 24 contacts. These contacts are so arranged with reference to the motor winding that arcing is impossible. A separation of 1-16" between rings and contact arms will open the circuit without carrying current across. The cylinder at the left carries the reversing rings and others for regulating the flow of current through the motor. Of these there are 10, and the resistance between them is so proportioned that no spark follows when a change is made, no matter how slowly the lever is moved. Near the bottom of the controller are a series of binding-blocks for making connection to the motor, current regulator and the line. These binding-blocks are plainly marked with letters and figures and correspond with others on the motor and regulator. With each controller is sent a diagram of the wiring. The cylinders for starting and regulating the current are compact and strong, with ample insulating resistance for use on any circuit up to and including 500 volts, and has sufficient metal in the contacts to carry a large excess of current without heating.

A complete installation of the above-described apparatus driving bending rolls will be illustrated in one of the succeeding issues of ELECTRICITY.

To Take Care of Growing Business.

At the annual meeting of the board of directors of the Phœnix Carbon Manufacturing Company of St. Louis, Mo., held on the 10th inst., it was unanimously decided, in view of the constantly increasing demand for Phœnix products, that the capital stock of the company be increased from $100,000 to $250,000. The increase of capitalization will be paid in at once and used for extension and enlargement of the present plant and to give better facilities for the growing business.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

INCORPORATIONS.

The Charleston Electric Railway and Power Company, Charleston, W. Va.—to own, operate, etc., lines of street railway, plants, etc., supply water, electricity, gas and other illuminating substances, motive power, etc. Capital stock, $500 minimum, $500,000 maximum. Promoters: Neil Robinson, F. L. Buttrick, D. W. Patterson, F. H. Markell, Charleston.

The Ohio Light, Heat & Power Company, Van Wert, Ohio—to manufacture and vend gas and electrical current for light, heat and power. Capital stock, $10,000. Promoters: C. L. Marble, Jno. E. Marble, Geo. Hayler, Jr., O. D. Swartout, Jno. B. Stevenson, Jr.

The Mutual Union Investment Company, Elizabeth, N. J. —to manufacture and supply electric light and power for all purposes, etc. Capital stock, $100,000. Promoters: Wm. S Stryker, Jno. W. Rehill, Somerville, N. J.; Jas. P. Powers, Elizabeth.

The following companies were recently chartered at Harrisburg, Pa.: The Ashley Light, Heat and Power Company, of Luzerne county, capital stock $50,000; the Sugar Notch Light, Heat and Power Company, of Luzerne county, capital stock $20,000; the Warrior Run Light, Heat and Power Company, of Luzerne county, capital stock $10,000; the Citizens' Avoca Light and Power Company, of Luzerne county, capital stock, $20,000. The incorporators in each of these four companies were the same, viz., Geo. McDonald and Geo. W. Milnes, Scranton, Pa.; John S. McCroarty, Wilkes-Barre, Pa.

The Boynton Bicycle and Traction Company of France (incorporated in W. Va.), New York, N. Y.--to acquire letters patent for appliances, devices, etc., for generating light, heat and power, etc., by electricity, steam, etc.; constructing railways in France. Capital stock, $10,000 minimum, $5,000,000 maximum. Promoters: Jose F. de Navarro, Thos. E. Sotolongo, Mariano de Cossio, Geo. R. Cullingworth, New York City.

The Boynton Bicycle Traction Company of Spain (incorporated in W. Va.), New York, N. Y.—to acquire letters patent, etc., for appliances, devices etc., for generating light, heat and power by electricity, steam, etc.; construct railways, etc. Capital stock, $10,000 minimum, $5,000,000 maximum. Promoters: Jose F. de Navarro, Thos. E. Sotolongo, Mariano de Cossio, Geo. R. Cullingworth, New York City.

The Charleston Traction, Light & Power Company, Charleston, W. Va.—to purchase, own, etc., lines of street railway, waterworks, furnishing, selling water, electricity, etc. Capital stock, $500 minimum, $500,000 maximum. Promoters: W. A. MacCorkle, Malcolm Jackson, M. M. Williams, A. W. Watrous, Charleston, W. Va.

The Atlanta, Knoxville & Northern Railroad Construction Company (incorporated at Albany, N. Y.)—to purchase, sell and otherwise deal in railroads and railroad equipment in the city of New York and in the States of Georgia, Tennessee and North Carolina. Capital stock, $92,500. Directors: Charles E. Kimball, of Summit, N. J.; Matthew F. McLanahan and George D. Mumford, of New York City.

The Port Jervis Electric Street Railway Company, Port Jervis, N. Y.—to build and operate an electric street railway seven miles in length. Capital stock, $70,000. Directors: Lafe Pence, George N. McKibben, New York; S. D. Lake, A. G. Haines, George Elston, J. E. Wickham, J. S. March, H. J. Cox and Theodore Shay.

The Brooklyn Bridge, Prospect Park & Eastern Railroad Company—to build a street railroad in Brooklyn and Flatlands, N. Y., 45 miles in length. Capital stock, $500,000. Directors: Anthony N. Brady, Albany, N. Y.; Fred. S. Flower, Edward Browne, Ira A. Place, William J. K. Kenny, Charles H. Werner, George M. Curtis, Jr , Walter H. Turner, New York, and John R. Pettit, of Brooklyn.

The Smethport & Olean Railroad Company—to build a railway line 18 miles long, from Smethport, Pa., to a point on the New York line in Eldred township, McKean County. Capital stock, $400,000. Directors: George J. Wolf, president; A. G. McComb, James George, H. A. Jackson, S. H. Smith and M. G. Raub, all of Bradford, Pa.

The American Machine Company, Cleveland, O.—to manufactnre electrical machines, machinery supplies, power and hand motors, etc. Capital stock, $100,000. Incorporators: Frank Mock, Theodore Bucker, M. D. Williams and others.

The Live Wire Cutout Company, Jersey City, N. J.—to manufacture appliances for street railway and electric light purposes. Capital stock, $250,000. William Kennon Jewett, New York City: Henry K. Wight, Springfield, Mass.; Robert M. Dixon, East Orange, N. J.

The Erwin Manufacturing Company, Greenbush, N. Y.—to deal in mechanical and electrical supplies. Capital stock, :5,000. Directors: John Erwin, W. W. Grey and R. J. Pratt.

The People's Electric Light, Heat and Power Company, Avoca, Pa.—to supply light, heat and power by means of electricity. Capital stock, $18,000 Promoters: Patrick F. Joyce, Pittston, Pa.; C. F. Bohan, Pittston, Pa.; J. T. Lenohan, Wilkes-Barre.

The Pittston People's Electric Street Railroad, West Pittston, Pa.—to construct an electric street railway. Capital stock, $50,000. Promoters: Jas. Flynn, Jos. C. Reap, Michael J. Langan, Pittston.

The Water, Light and Power Company, Herington, Kan. —to put in and operate a plant for electric lights and waterworks in Herington. Capital stock, $30,000. Directors: J. S. Brundage, H. S. J. Towner, T. M. Bixby, P. G. Dayton and R. A. Wilson.

The McKee's Rocks Electric Light Company, McKee's Rocks, Pa.—to supply light, heat and power by means of electricity. Capital stock, $20,000. Promoters: David Shaw, Al. Young, Mckee's Rocks, Pa.; Thos. S. Calhoon, Esplen, Pa.

The Sacramento Natural Gas Company, Stockton, Cal.—to bore for gas, oil and water and manufacture gas, oils, ice and electricity. Capital stock, $120,000. Promoters: Jerome Hass, Henry C. Keyes, Thos. Quayle, Jno. McCormick, Stockton, Cal.

The Electric Railway Hill-Cable Company, San Francisco, Cal.—to construct, repair cable and electric railways, purchase patent rights relating to railways. Capital stock, $1,000,000. Promoters: N. W. Griswold, Wm. H. Birch, Jno. L. Boone, San Francisco.

The Brockville Electric Street Railway Company, Limited, Brockville, Can.—to build a street railway in Brockville. Capital stock, $200,000. Incorporators: W. H. Comstock, W. A. Gilmour, C. S. Cossitt, D. S. Booth, G. J. Mallory, O. K. Fraser and M. M. Brown, all of Brockville.

The Lincoln Street Railway, Traction & Light Company, Limited—to build and operate an electric railway in St. Catharines, Can., and to sell and distribute electricity for light, heat and power. Incorporators: R. H. Hill and H. A. King, Toronto, and J. S. Campbell, Dr. L. S. Oille and George E. Patterson, of St. Catharines.

The Toronto (Can.) Electric Light Company has increased its capital stock from $500,000 to $700,000.

The Syracuse Gas Company, Syracuse, N. Y.—to manufacture and supply both gas and electricity for light, heat and power in Syracuse and the cities, towns and villages within the State of New York. Capital stock, $2,500,000. Directors: Robert C. Pruyn, of Albany; Stephen Peabody, Emerson McMillan, Henry Seligman and A. C. Humphreys, of New York City; William L. Elkins, Jr., of Philadelphia; James J. Belden, John Dunfee, Charles M. Warner, William S. Andrews, Thomas Ryan, William B. Kirk and Hamilton S. White, of Syracuse.

The Akron Street Railway and Illuminating Company, Akron, O.—to acquire and operate a street railroad, using electric or other motive power. Capital stock, $1,500,000. Promoters: J. B. Clews, J. A. Long, F. A. Seiberling, E. B. Gibson, Ira M. Miller.

The Corry Street Railway Company, Corry, Pa.—to build an electric street railway. Capital stock, $25,000. Promoters: G. W. Sill, Chas. B. Ayers, S. J. Franklin, Warren, Pa.

The Port Chester Electric Railway Company—to construct a street surface road about ten miles in length in the village of Port Chester, N. Y. Capital stock, $500,000. Directors: Thomas S. Krutz, John E. Bowles, Theodore L. Cuyler, Jr., Charles P. Bruch, George E. Boucheir, Albert E. Beck, David J. Pearsall, and Henry F. Hawkins, all of New York City.

The Kimball Magneto-Electric Prospecting & Development Company, San Francisco. Capital stock, $500,000. Directors: L. J. Kimball, A. P. Bacon, Frederick Hiller of San Francisco, and J. W. Guthrie and W. F. Jackson of Sacramento.

The Elliott Magnetic Electric Company of Chicago has certified to an enlargement of object of incorporation.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 10, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

550,965. Electrical Conduit Railway. John D. Griffen, New York, N. Y. Filed Dec. 5, 1892.

551,021. Electric Rail-Bond. William H. Wiggin, Worcester Mass. Filed May 22, 1895.

551,145. Switch for Underground Electric Railways. Alfred Rosenholz, San Francisco, Cal, assignor of one-half to Samuel J. Clark and Harvey S. Brown, same place. Filed April 12, 1895.

551,168. Trolley. David Lippy, Ira E. Finfrock, George A Rinehart, and David R. Francis, Mansfield, Ohio. Filed Sept. 24, 1895.

551,169. Trolley. David Lippy, Ira E. Finfrock, George A. Rinehart, and David R. Francis, Mansfield, Ohio. Filed Sept. 24, 1895.

551,334. Electric Railway. Robert Lundell, Brooklyn, assignor to the Johnson Subtrolley Company, New York, N. Y. Filed June 9, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

550,956. Carbon-Holder for Arc Lamps. Hugh J. Farley, Philadelphia, Pa. Filed Dec. 15, 1894. Renewed Oct. 7, 1895.

551,029. Electric-Arc Lamp. William J. Davy, London, England. Filed Apr. 19, 1895.

551,046. Electric-Arc Lamp. Frederic N. Pike, New York, N. Y., assignor to himself and Edward N. Dickerson, same place. Filed June 27, 1894.

551,244. Electric-Arc Lamp. Wm. P. Wiemann, Washington, Pa., assignor of one-third to H. P. Chambers, same place. Filed April 17, 1895.

551,337. Electrode for Arc Lamps. Thomas G. Portis, St. Louis, Mo. Filed May 14, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

551,033 Commutator-Brush. Robert Hirsch and Herman Meminger, Milwaukee, Wis. Filed Jan. 28, 1893.

551,053. Electric Controller. Sidney H. Short, Cleveland, Ohio. Filed Aug. 26, 1895.

551,054. Electric Controller. Sidney H. Short, Cleveland, Ohio. Filed Aug. 27, 1895.

551,263. Antisparkle Commutator Compound. John R. Davis, New Iberia, La., assignor of one-half to Margaret M. Davis, same place. Filed Mar. 30, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

550,982. Harmonic Selective Signal for Party Telephone-Lines. James A. Lighthipe, San Francisco, Cal. Filed June 24, 1895.

551,056. Multiple-Switchboard System. Theodore Spencer, Cambridge, and Thomas C. Wales, Jr., Boston, assignor to the American Bell Telephone Company, Boston, Mass. Filed Mar. 18, 1895.

551,060. Telephone-Circuit. John S. Stone, Boston, Mass., assignor to American Bell Telephone Company, same place. Filed July 6, 1895.

551,192. Telegraph-Relay. Archibald D. MacDonald, Melbourne, Victoria. Filed Nov. 2, 1894.

551,275. Telephone-Transmitter. John Goodman and Henry M. Goodman, Louisville, Ky. Filed June 14, 1895.

551,347. Telephone-Receiver. Alfred C. Brown, London, England. Filed July 11, 1895.

MISCELLANEOUS.

550,959. Electric Clock. Benjamin Franklin, Chicago, Ill., assignor of three-fourths to David H. Fletcher, George H. Merriell, and Calvin R. Beach, same place; Mary A. Franklin administratrix of said Benjamin Franklin, deceased. Filed April 1, 1893.

551,014. Electric Smelting-Furnace. Joseph A. Vincent, Philadelphia, Pa. Filed July 18, 1895.

551,020. Electromagnet. Samuel T. Wellman, Upland, Pa., assignor of one-half to Charles H. Wellman, same place. Filed April 18, 1894.

551,032. Cleat for Electric Wiring. James R. Hemphill, Akron, Ohio. Filed Sept. 26, 1895.

551,087. Mail-Collection System. Charles F. Monson, Baltimore, Md., assignor of one-half to J. W. Couch, Petersburg, Va. Filed Aug. 30, 1895.

551,090. Signaling Apparatus. Bernice J. Noyes, Boston, Mass, assignor to George W. Gregory, same place. Filed Sept. 11, 1889.

551,123. Successive Non-Interfering Signal-Box. William H. Kirnan, Brooklyn, assignor to The Gamewell Fire-Alarm Telegraph Company, New York, N. Y. Filed Aug. 18, 1890.

551,166. Joint for Insulated Electric Wires. Raymond S. Kelsch, Chicago, Ill. Filed Dec. 22, 1894.

551,170. Switch for Electric Plants. Austin H. Lucas, Pittsburg, Pa. Filed Jan. 4, 1895.

551,203. Electric Switch. John E. Criggal, Springfield, Mass. Filed Jan. 15, 1895.

551,230. Composition of Matter for Insulating Purposes. Rufus N. Pratt, Hartford, Conn., assignor to the Johns Pratt Company, same place. Filed Oct. 31, 1889.

551,284. Electric Sunshine-Annunciator. Leonard Hunt and Frederick W. Duenckel, St. Louis, Mo. Filed May 20, 1895.

ELECTRICITY.

Vol. IX. NEW YORK, DECEMBER 25, 1895. No. 24

ELECTRICITY

Published every Wednesday by the

EDITORIAL NOTES.

Isolated Plant Design. That the perfection of the design and details of our large central stations has not entirely engrossed the attention of our constructing and consulting engineers is evident to those of the profession who have given any attention to the installation of isolated plants. The magnitude of many of our large central stations has, perhaps, appealed more strongly to most persons than has the smaller, though none the less interesting, private installations. The opportunities and possibilities for boldness of design and elaborateness of detail are quite as great in one class of installation as another, and have been carried out with equally satisfactory results in either case.

While highest economy of operation has been the chief aim in the equipment of central stations, this desideratum has been subordinated to no demand in the designing of isolated plants. Safety and efficiency are factors of as essential importance in isolated as in central station work. In fact, modern practice, when applied to either class of work, embodies all that is best.

In this issue of ELECTRICITY description is given of some notable isolated installations which will long stand as examples of the highest attainment in the art.

* * *

Some Bugbears of Electric Traction. The *American Engineer and Railroad Journal* has found that the electrical railroad man is not without sorrows, nor is he entirely unacquainted with grief. His woes, our contemporary discovers, are chiefly of a mechanical kind, but they are none the less real on this account. Introductory to an enumeration of them, we are told the story of a king who once made the experiment of running a number of clocks in exact unison. He made such a failure of it that "no one has since had the courage to so much as make the attempt until electricians started in to do practically the same thing by putting two motors upon a single car and hoping, though they knew that there was no ground for expecting a realization of their hopes, that all would work well and satisfactorily."

Evidently expectations have not been realized for "this, and the difficulty existing in the present use of gears for transmitting power from the armature shaft to the axle are the two great bugbears of electric traction."

Our contemporary thinks the difficulties of supporting a motor on the car axle have not yet been overcome, although somewhat mitigated by the most recent designs in motor frames. The rapid wearing of car wheels is considered to be another apparently insuperable fault common only to electrically propelled cars. These and other defects which entail an ever increasing repair account are enumerated as falling exclusively to the lot of street railway men, for whom little comfort is offered inasmuch as "it is difficult to see how a combination can be designed that will obviate all of the troubles that exist." Some encouragement, slight though it be, may be found in the conclusions of our steam road friend: "That the problem will be so solved that all of the difficulties will be removed does not appear to be the promise of the immediate future, but that the evils complained of will be at least mitigated seems to be in the line of general development, and should be the natural result of the efforts that are being made."

Those street railway men whose misfortune it is to have in their care inferior or antiquated apparatus would doubtless be able to augment the list of troubles enumerated by the *Journal*, as well as to subscribe to the correctness of the conclusions reached, but the manager of the modernly equipped electric railway will still incline to the belief that even a complete approximation of steam railroad practice will not eliminate all the "bugbears" of the traction problem.

* * *

The Underground Trolley Problem. Our correspondent "West End," who criticises Capt. Brophy this week for making a somewhat careless statement as to the burial of all trolley wires in large crties, although expressing radical views, has a thorough knowledge of all the various problems confronting practical railway men and can speak with authority.

In mentioning the obstacles standing in the way of a successful underground system for Boston, he tells that in one day more than 100 motors have been disabled on the West End road by running through pools of water in the low-lying districts deep enough to submerge the motor, and that the drainage of these neighborhoods is impossible. This is a condition which the promoters of underground systems and railway men generally should thoroughly consider before making heavy investments in any given locality. The same conditions exist, in perhaps smaller degree, on the streets covered by the Belt Line in this city, which it is proposed to equip with a practical duplicate of the Lenox Avenue system. Whatever may be the possibilities of open-conduit systems for certain localities, there is scarcely a doubt that every dollar expended in streets like West and South streets in this city would be absolutely wasted, and that there would have to be a change of motive power. It is not possible that in such neighborhoods, the storage battery system, no matter what its cost, may be adopted as a last resort? The people demand rapid transit. Horses can not give it. The trolley will not be tolerated in this city. Cables are out of the question on many routes here, as they are in

Boston, on account of innumerable curves. What is there left?

* * *

The Majesty of the United States.

Most readers of ELECTRICITY have given a great deal of thought during the past week to the question of the position which the United States occupy among the nations of the earth. It is a good subject to think of.

The renewal of the declaration by our Chief Magistrate that there shall be no further encroachment by any foreign power on American soil from the Canadian line to the southernmost rock of Cape Horn has had the result of crystallizing American sentiment in a manner which shows that patriotism is not yet dead in this the greatest of countries.

Under an attack from the Shylocks of Lombard street there was some disturbance in the business world, and some few business men, in the irritation of the moment, were led to criticise the action of the President in precipitating a crisis. We believe every one of these misguided gentlemen now regrets his haste in placing himself on the wrong side. In the first place the flurry is over; there will be no panic.

Moreover, if there were a panic and a complete upset of all business and commerce, *that has nothing to do with the question at issue.* The United States are either right or wrong. If we are wrong, criticism should be above business considerations, and if we are right, we should maintain our position at any cost.

The people of the country are practically a unit in support of the position taken by the President—the position taken by all patriots and statesmen for seventy-five years. The people of the United States of America can not be wrong.

The only discordant notes in the grand chorus of practical Americanism have come from a few clergymen whose remarks would rarely be printed if they did not take some outlandish view of a popular subject, and from one newspaper in New York, the *Evening Post*, whose editor, Mr. Edwin Lawrence Godkin, is not, we believe, a naturalized American citizen. Mr. Godkin is a graduate of Trinity College, Dublin, and a man of learning and ability, but since his connection with the *Evening Post* he has managed to land that paper on the wrong side of every international question where America has been concerned. The *Post* says:

"The fact is we have not a friend in Europe to-day. From France, Germany, Italy, Spain, and every other country that has a free press the word comes that we are in the wrong."

From France, *Germany*, ITALY, SPAIN comes the word that the United States are wrong in a dispute where one of the fundamental principles of the the American Republic are at stake! No surer proof could be needed that we are right.

The same paper refers, with an attempted sneer, to those Americans "who have heard of no international law except the Monroe doctrine."

On the subject to which the Monroe doctrine applies, what use has any American for any international law?

No such law has any bearing upon the present controversy.

The Monroe doctrine is *our law*.

In enforcement of that law the United States stand supreme, defiant, unconquerable.

A Cable to Iceland.

The Iceland Althing has requested the King of Denmark to communicate with other nations in regard to laying a cable from Iceland to the continent of Europe. The resolution calls special attention to the importance of such a cable in the interest of meteorology.

The Pacific Cable.

Representatives of New South Wales, Victoria, and Queensland, have decided to appoint delegates to the Pacific cable conference, to be held shortly in London.

Under the Searchlight.

Views and Opinions on Timely Topics.

Extravagance at Catausauqua.

(From the Catausauqua, Pa., Record.)

A short time ago electric lights were introduced upon our streets. This was a prodigious waste of money. With the sun shining at day and the moon at night what a useless expenditure? No, electric lights were not a necessity, and the borough did wrong to contract for them.

* * *

The First Electric Light in an American Theater.

It is believed that the first electric light installed in an American theater was a Jablochkoff candle used as a focussing lamp in the old California Theater in Bush street, San Francisco, in 1878. The managers of the theater at that time were Messrs. Barton Hill, General Barton and Frank Lawler. The play was "Antony and Cleopatra," Rose Eytinge and Cyril Searle taking the leading parts. Mr. A. H. Reece was the engineer in charge of the work.

Seventeen years have worked a complete revolution in theatrical lighting, and to-day there is not a theater in the United States which could dispense with the electric light.

* * *

He Wants Peace.

The entire office force of ELECTRICITY was surprised and pained when the following was received:

6 Joy street,
Boston.

Mr. Robert Treat Paine requests that you do *not* send ELECTRICITY to him as he never opens it or reads it. *Per* Priv. Secy.
December 20, 1895.

Mr. Robert Treat Paine is (or was) a large holder of G. E. and N. W. G. E. stocks. He is also president of the American Peace Society, and from the tenor (or falsetto) of his remarks to us, as from the sentiments expressed in his recent letter to Salisbury, it is evident he wants peace. But there are some things which should not be forgotten. It is just as sure as it was three hundred years ago, when the thought was first expressed by a well-balanced Puritan divine, that

"that peace is an evil peace that doth shut truth out of doors. If peace and truth cannot go together, truth is to be preferred, and rather to be chosen for a companion than peace."

ELECTRICITY is chock full of truth, and there will never be any peace in this trade until the truths inculcated by it are recognized.

* * *

The Standard Viewed from England.

(From the London Electrician.)

An enterprise heralded some months ago in the manner of earlier electrical promotion days seems coming to a crisis. We refer to the Standard Telephone Company, which last April announced with a great flourish its entry into the field as a rival of the Bell monopoly. A capitalization of no less than $160,000,000 was claimed, and a list published of its supporters, which comprised some of the most prominent names in the United States. Mysterious allusions were made to wondrous telephonic patents which in due time would be disclosed, and a telephonic service at a merely nominal price was promised. Thus far, however, the company has made no installations and has given no evidence whatever of the possession of any telephone patents beyond claiming to control some old ones well known in telephone circles, and which have never been supposed to possess any practical value. At present the company is being vigorously attacked, the charge being made that it was merely formed to obtain money from the numerous branch companies which were organized through false representation as to non-infringing apparatus, by means of which it was asserted successful competition with the Bell Company could be undertaken. No satisfactory answer has been made to these charges, and the very respectable gentlemen whose names have been the sole stock-in-trade of the company are beginning to recognize that they may have been used as decoys in a rather disreputable scheme.

* * *

THE difference between General Electric and Westinghouse stocks was made conspicuous by the recent flurry. General Electric shares declined nearly ten points in one day, thereafter making a slight recovery. Westinghouse shares have not moved a point either way.

* * *

THE process of closing up the business of the Brush Company at Cleveland goes on as rapidly as could be expected with such a concern. It is believed by those best posted that the early part of 1896 will see the entire business transferred to Schenectady.

* * *

He Is For War.

The Destructive "Electric Fuse-Train" and its Inventor.

To Edwin Gomez, of 112 East 87th street, New York City, belongs the credit of being the first inventor to enter the electrical field with death-dealing devices, which may be used in sinking English iron-clads or in the more peaceful art of blasting rocks. The invention of Mr. Gomez is called the "Electric Fuse Train," and its object "is to effectually retain the force of exploding gun powder, so that none of it is lost, but simply directing its force to any desired point." The circular announcing this discovery to a war-talking world does not give a detailed description of the invention, but states that the Electric Fuse Train "burns with a sudden and an irresistible flash, the flame and explosion traveling with so great a velocity that it can never be put out by the pressure of water when submerged; and when the flame reaches the torpedo, shell, mine, etc, the coil of fuse train, flashing off, fills the powder-chamber instantly with an intensely hot, confined flame that penetrates the powder and causes every grain to explode at the same instant."

MR. EDWIN GOMEZ.

By employing this apparatus in igniting gunpowder or other explosives, "an entire revolution may be produced" and "results never before attained may be accomplished, because all the grains of powder are fired at the same time, in consequence of the fuse train being coiled all through the powder and producing a sufficient flash to penetrate and fill the spaces between the grains of powder in every portion of the powder-chamber. This fuse-train is perfectly reliable and excels every other means of communicating fire to one or more charges of powder, torpedoes, shells, mines, blasts, etc., either near together or distant from each other—one line of the fuse train only being required for any number of explosions."

American Institute of Eectrical Engineers.

At the monthly meeting of Council, Dec. 18th, the following associate members were elected: Chas. F. Bancroft, Lowell, Mass.; Frank E. Herdman, Winnetka, Ill.; Richard Lamb, New York City; Leon Le Pontois, Pittsburg, Pa.; Harry W. Ludlam, New York City; Samuel G. McMeen, Chicago, Ill.; Frank L. Scidmore, New York City; Joseph P. Stone, Schenectady, N. Y.; Norman W. Storer, Wilkinsburg, Pa.; Chester H. Thordarsson, Chicago, Ill.; Harrison C. Wybro, Los Angeles, Cal.

The following associate members were transferred to full membership, their applications having been approved by the Board of Examiners: George Stephens

Peterboro, Ont.; George White-Fraser, Toronto, Ont., Alex. Dow, Detroit, Mich.; Samuel G. Neiler, Chicago, Ill.; Knowles L. Perot, Phœnixville, Pa.; John Balch Blood, Schenectady, N. Y.; Franklin Sheble, Philadelphia, Pa.; William H. Freedman, New York City; Andrew L. Riker, Brooklyn, N. Y.; John A. Mc Crossan, Rat Portage, Ont.

The following committee was appointed by President Duncan to consider the question of incorporation of the Institute and any revision of the constitution that might be necessary to comply therewith: W. B. Vansize, Esq., Chairman; Prof. H. S. Carhart, Mr. W. F. C. Hasson, Mr. A. S. Hibbard, Dr. Cary T. Hutchinson, Mr. T. C. Martin, Mr. Townsend Wolcott.

CORRESPONDENCE.

CAPT. BROPHY'S ADDRESS.

Is He Working in the Interest of Boston Shoe Dealers?

To the Editor of ELECTRICITY.

SIR: Boston is deeply interested in the boot and shoe business, and being so, naturally desires to encourage walking as much as possible; indeed some of its citizens do not hesitate to advocate the total abolition of all street railway traffic from its streets, or at least counsel legislation which would have this effect if carried out. Amongst the loyal partisans of the local Crispins we must include our old friend Capt. Brophy, who said in his recent speech:

> "As you all know, the State Legislature passed a law applicable to the city of Boston, compelling the owners of all electric wires within a certain prescribed district to place them underground prior to the first day of January, 1900. This includes electric wires of every name and nature, with the single exception of the overhead trolley of the West End Street Railway Company. To the average man, the reason for this exception on the part of the body that sits under the "gilded dome" seems inexplicable. For my own part, I have never been able to fathom the motives that control the actions of our legislators at different times, and as a matter of fact I deem my life too short to attempt to do so. It is plain to me that if the electric light, power, telegraph, telephone, fire and police wires are dangerous enough to be removed from poles and other structures and placed under the surface of the street, the bare trolley should find a similar resting-place. If, as it is assumed, the aim and purpose of this law was to add to the safety of the public, by removing what is considered a serious menace thereto, it falls very far short of its purpose when it permits this class of wires to remain above the earth while all others are placed beneath it."

He added later in the same evening: "There was little or no danger in the 500 volt current used by the railway trolley system."

Now if the Legislature had ordered the trolley wire taken down in the city of Boston at the present time, as Capt. Brophy thinks they logically should have done when they ordered down all the others, it would have resulted in stopping all street railway traffic in that city. There are three alternatives, as far as Boston is concerned, to the trolley system in sight, viz., the underground-conduit system, the storage-battery system and horses. There are closed-conduit systems which will probably be worked out in the future but are altogether in too embryotic a state at present to be considered as a factor.

It would be a physical impossibility to operate an open underground-conduit system in the city of Boston. There are hundreds of places in that city where the conduit would be flooded repeatedly and the system short-circuited, and no system of drainage could prevent it. This is said advisedly. There have been times when upward of 100 motors in a day have been rendered inoperative by running through the pools of water that settle in the low lying spots with which Boston is so well supplied. There are cities where this system can be applied successfully, but Boston is not one of them. Then again, taking the cost (and this has to be considered), the conduit alone would not cost less than $75,000 per mile, and the West End Railroad has upward of 270 miles of track; in addition to this then would be the equipment of cars, adjustment of feeders, drains, etc., and with no addition to revenue no interest on the investment could be shown.

Any known system of storage-battery traction would bankrupt the company in a very few months.

So there only remains the alternative of going back to horse cars or walking. If they go back to horses, the company must resign itself to lose all they have invested in their present plant and raise capital again to purchase a fresh stock of horses and cars.

Instead of being "inexplicable" as Capt. Brophy says, this exception of trolley wire in the general order of removal of wires was both wise and unavoidable, no matter what the "average" man may think.

Both in virtue of his official position and his long and honorable career, Capt. Brophy's word carries weight second to none; his character and attainments compel respect both for his truth and judgment, and it is rather surprising to find him, usually so careful and accurate in his statements, slipping into a bit of "clap-trap" like that quoted. Irresponsible cranks, vague dreamers, interested "inventors," half-baked electricians and others, either through ignorance or thoughtlessness may make such statements with no other effect than that of inducing "that tired feeling" in their hearers, but with Capt. Brophy it is different, and it behooves him, and responsible men like him, whose opinions and advice are likely to be crystallized by action upon the part of those in authority, and who have to rely upon such as him for guidance, to be careful in not making such loose and misleading remarks for the sake of a little temporary effect in a post-prandial address.

WEST END.

Boston, December 20, 1895.

The Peck Electrical Company.

Mr. E. F. Peck the vice-president of the National Electric Light Association, who for the last ten years has been the general superintendent of the Citizens' Electric Illuminating Company of Brooklyn, has formed a company to be known as the Peck Electrical Company, with an office at 15 Cortlandt street, New York. The company proposes to manufacture and deal in electrical specialties and supplies, and also to engage in electrical engineering in all its branches. Mr. Peck's long and practical experience as superintendent of one of the largest and most successful electric lighting plants in the country, together with his recognized capacity as an electrical engineer, will undoubtedly command for the company a large share of public and private patronage.

PERSONAL.

Mr. Westinghouse has taken the Blaine mansion at Washington for the winter.

Mr. James Partridge of the Partridge Carbon Company was a New York visitor last week. Mr. Partridge was with Brush in the latter part of the '70's, and always has a few interesting reminiscences of the early days when light carbons were selling at $160 a thousand.

Mr. Stanley S. Stout of Chicago was in New York and Boston this week taking testimony in the litigation between the Bell Company and the Western Telephone Construction Company.

Mr. W. P. Roberts, of Lynchburg, Va., who has organized several independent telephone exchanges in the South, has been in town this week purchasing supplies.

Mr. E. H. Forst, of the California Electrical Supply and Construction Company, has been spending several days in New York on business.

The Okonite Company's Annual Meeting.

The annual general meeting of the Okonite Company, Limited, was held at the office of the company, 13 Park Row, New York City, on Wednesday last, December 18, at 12 o'clock noon. A number of matters of interest to the company were discussed. The accounts were also presented and passed.

Subway Work in Brooklyn.

The annual report of the Commissioners of Electrical Subways in the city of Brooklyn shows that the aggregate length of electric conductors of all kinds within the city limits is 20,371 miles, of which 3,599 miles were added during the past year. Over 12,000 miles of wire is placed underground or suspended beneath the elevated railways. The underground conduit now in place is 126 miles in length; length of single duct, 343 miles. Until specific appropriation is made the wires of the police and fire departments cannot be placed in subways. The Board of Estimate is called upon to provide a sum for the purchase of new wires and cables for the city's telegraph system.

"The work of the extension of the telephone system during the year," the report says, "has been unprecedented, owing in part probably to the adoption by the company of cheaper rates for a certain class of service, such as the ordinary householder wants, and partly to the natural inevitable growth of the system."

Bimetallic Wires in Germany.

Experiments have recently been made by the German Postal Telegraph Administration with bimetallic wires in order to see if they could compare with bronze wire for telephonic purposes, both in respect to their mechanical and electrical properties. It is claimed for these compound wires that they have important properties. For example, a telephone line with a bimetallic conductor will work much more perfectly than with a conductor of a single metal such as copper. Again, it is claimed that less insulation is needed for such a conductor than for copper or any other material, and hence such wires laid on the earth without special insulation permit telephonic communication to a much greater distance. A number of experiments were recently conducted for the German post-office by its telegraph engineers to ascertain the facts. The results obtained do not go to show that the double-metal wires are any more valuable than the pure copper wire, but that the distance to which telephonic transmission by bare wires laid upon the earth is possible depends mainly upon the size and weight of the wires, presuming all the conditions are similar.

Incandescent Lamps in Germany.

In a recent number of the *Elecktrotechnische Zeitschrift* there appears the report of the commission which was appointed by the Union of Representatives of Electricity Works in Germany to investigate the incandescent lamp question. The report states that "the complaints of consumers that the incandescent lamps are bad—good for nothing—are justified." As the causes of this regretable condition of things it gives: imperfect sorting, false marking, little economy and too short life of the lamps. In 70 lamps supplied by eight makers, which were given as 16 standard candle-power, and whose rate of consumption should have been 3.25-3.50 watts per candle-power, the illuminating power fluctuated between 7.82 C. P. and 22.85 C. P. and the rate of consumption between 2.8 and 6.3 watts per candle-power. One of the very first German firms supplied 20 lamps specially for the investigations. In these 20 the illuminating power fluctuated between 10.21 C. P. and 21.6 C. P., while the consumption in watts averaged 4.1 per candle-power. In ten 16 C. P. 3.5 watt lamps from another first-class firm the illuminating power decreased in the course of 48 hours' burning by from 40 to 60 per cent., while the consumption in watts per candle-power rose on the average to 5.6.

A Boston Failure.

W. B. Southgate & Company, dealers in electric supplies, 146 Franklin street, Boston, have filed a petition in insolvency.

Electric Traction in Spain.

A 60-years' concession has lately been granted to a company for the construction and operation of an electric tramway between Cadiz and San Fernando-Chulara. Work on the establishment of the line has just been commenced.

The Storage Battery.*

A DISCUSSION OF ITS APPLICATIONS BY THE MEMBERS OF THE A. I. E.E.

THE STORAGE BATTERY OR THE GAS-ENGINE AS AN AUXILIARY.

BY NELSON W. PERRY, E. M.

Whether it is economical or not to equip a central station with an auxiliary storage battery plant is a question which must be decided separately for each particular installation. Aside from purely economic reasons, convenience may be controlling, so that it is impossible to state, unless all the conditions are known, whether the storage battery is advisable or not. The price of the battery is an important element of course, but less so than popularly supposed, for the space which it occupies and the cost of maintenance may largely overbalance any gain in first cost over the cost of the extra boiler, engine and dynamo.

In regard to the cost of maintenance, manufacturers are willing to guarantee that it will not exceed 10 per cent. per annum, but it is well to understand just what this 10 per cent. means. It means, in the first place, that if you put in all the battery power that the manufacturer recommends, and take care of the battery exactly as he says, then the guarantee holds good. Under such conditions, the manufacturer is undoubtedly safe, but if we install a plant under these conditions we are pretty sure to find that the economy in first cost of the battery over engine and dynamo has entirely disappeared.

Then it is well to understand beforehand what the 10 per cent. means—10 per cent of what?

Some time ago I had occasion to inform myself accurately on this subject, and to this end entered into quite a correspondence with the president of the leading storage-battery company of this country. As regards the guarantee, he wrote me under date of June 18, 1894, as follows:

> We send you by to-day's mail our illustrated catalogue, and would especially call your attention to the question of maintenance as contained on page 11. We undertake in these cases to provide renewals when renewals are required at a specific price with a guarantee that this will not be required sufficiently frequent (*sic*) to exceed an average of 10 per cent. per annum. We have every reason to believe from our experience so far that the actual cost of maintenance when the batteries are used at normal rates will not exceed 5 per cent.

Turning to page 11 to see what this meant, I found the following:

> This company is prepared to undertake maintenance contracts, according to a scheduled rate of charges, for periods up to 10 years or longer, under which they will guarantee that the total amount paid for renewals during the term of the contract shall not exceed 10 per cent. per annum on the *catalogue* price of the cells specified in the contract. . . . *In all cases of renewal by* contract the old material becomes the property of the company, *and must be returned to their works free of charge for carriage or packing.*

[The italics are mine.]

Since the regular trade discount at that time was 20 per cent. off the catalogue price, and a further discount was offered which made the cost of the batteries comparable with that of an engine and dynamo, the guarantee assumed a very different aspect from that which it bore on its surface. When to this was added the cost of packing and carriage back to the factory, it ceased to be an attractive guarantee, and my calculations showed that in many cases where the storage battery might be recommended if the guarantee was what it appeared to be, it would not be economical under the guarantee as it actually was.

As before indicated, there are some situations in which either convenience or extreme steadiness of current may be controlling in deciding the question of the use or not of storage batteries. But where the question is one purely of economy, I would not myself recommend their use under any circumstances, simply because there is a still more economical method at hand. I refer to the gas engine. Even if it were necessary to use illuminating gas from the street mains it would be more economical (considering space and other factors) to take the peak of the load with a gas engine than to install a battery for this purpose. In this case there would be no standby losses, and the engine would be ready at a moment's notice to be thrown into service.

It is a fact that has been amply demonstrated by others as well as myself, that a given number of lights can be produced with half the gas burned in a gas engine that is required to produce them in ordinary burners. The mechanical efficiency of the gas engine is not quite so high as that of large compound condensing steam engines, rarely ever exceeding 83 to 85 per cent. while the latter may go to 90 per cent., but the total efficiency from fuel to the pulley of the gas-engine is about double that of the steam-engine—reaching 25 per cent. under favorable conditions, whereas with the steam engine it rarely equals 12 per cent. So that with the gas engine operating at anywhere near its full load, there would be a gain in efficiency, instead of a loss, of, say, 20 per cent. where the battery was used.

As indicating the performance of a gas engine using illuminating gas at various loads, I quote the following figures obtained from a test of a 12-H. P. (actual) gas-engine:

Actual H. P. developed.	Gas consumption (cub. ft.) each actual H. P.
12	15
11	15.3
10	15.5
9	16
8	16.5
7	17
6	18
5	19
4	21
3	26
2	30
1	48

These figures are somewhat better than would be obtained in practice, but go to show that the gas engine compares favorably at light loads with the steam engine under similar conditions.

Thus far I have spoken only of illuminating gas, but the power may be much more cheaply generated by using a fuel gas. The cost of producers or generators comes to about $11 per H. P. capacity—considerably less than the cheapest boiler—and an idea of the space required may be gained from a statement of Mr. J. Emerson Dowson, who in estimating for a plant of 400 K. W. capacity says that if the gas plant is all on one level it would occupy a ground space of 27 ft. x 54 ft., but, if necessary, all except the gas holder can be placed under or over the engine room. His estimate for such a plant is, including erection, foundations and ash-pit for generators, $5,500, or $10.38 per H. P.

These fuel-gas generators can utilize advantageously the poorest grades of fuel, and produce from the better grades of anthracite about 160,000 cubic feet of gas of a calorific value, equal to one-quarter that of 16 C. P. illuminating gas, per ton of coal.

As to the standby losses of the gas producers, this has been very carefully determined in a number of cases. As an illustration I will cite a single case—by no means the best on record. At Openshaw a generator which supplied gas for from 250 to 300 I. H. P. was shut down for 41 hours and the fuel consumption during this time was but 3.9 lbs. per hour, or about 1 per cent. When we compare this with the standby losses of the steam boiler, which are estimated by Prof. Kennedy at 10 per cent. of the total consumption in all the boilers, we see how insignificant it is. A situation usually considered peculiarly adapted to the storage battery is in subordinate or outlying stations where they are charged during the daytime from the central station and act as centers of supply during the night-time.

But gas can be much more economically distributed to these stations than can the electric current, for Mr. Denny Lane has shown that with ordinary 16 C. P. gas, 3,000 H. P. can be sent a mile for an expenditure of 1 H. P., or one-thirtieth of 1 per cent. of the power conveyed. My own calculations show that a 6-in. pipe will deliver 6,000 cub. ft. of gas per hour at a distance of 10,500 ft. under 4 in. of water pressure. If this be 16 C. P. gas, allowing 25 cub. ft. per H. P. hour, this quantity represents 240 H. P.

Cast-iron pipe, 6 in. in diameter, having a thickness of ½ in., weighs 31.9 lbs. per foot. The total weight of this 2 miles (nearly) of pipe will therefore be 334,950 lbs. This would be equivalent in conductivity to about 41,869 lbs. of copper. But 4 miles of copper weighing 41,869 lbs. would be equivalent to about four No. 000 B. & S. wires, which would have a resistance for the 4 miles of 0.325 ohms. If the charging current were transmitted at 220 volts, there would be required a current of 848 amperes; but a wire having a resistance of .325 ohms will only deliver under a pressure of 220 volts; 220 ÷ .325 = 677 amperes; there would, therefore, be required five No. 000 B. & S. wires to deliver this energy, and the weight of this would be 53,540 lbs.

If the distribution took place at 1,000 volts, the amperes required would be approximately 180. To deliver this at the same distance with a loss of 10 per cent. would require 6,264 lbs. copper, and to deliver it at 1 per cent. loss would require 62,642 lbs., which would cost far more than the pipe and still give less efficient transmission.

I think it would be very easy to prove that the gas engine with fuel gas would prove a much more economical auxiliary to the central station for taking the peak of the load and the loads amounting to fractions of a unit than the storage battery; and when we consider the efficiency of transmission of energy in the form of gas, which will permit of the location of the gas generators where land is cheap and fuel easily procured, it seems to me that the plan must commend itself to electrical engineers.

Unfortunately the gas-engine business in this country seems to be in the hands of parties totally incompetent to handle it properly, as every one knows who has ever had occasion to seek information from them.

It is probably not too much to say that every attempt thus far made in this country to adapt the gas engine to electric lighting has proved a failure. Our own manufacturers either do not know what their engines are capable of doing, or else they are afraid to make public what they will do. I believe there is not a single manufacturer who has a printed price-list, and my own experience and that of others whom I know, has been that it is impossible to get prices quoted until the manufacturer or his agent has been thoroughly satisfied of the exact purpose for which the quotations are desired. Information of any kind is almost impossible to get; and guarantees of performance, when given, are worthless. To such an extent is this true that nearly all, if not all, the recent large orders for gas engines have gone abroad, where the business is conducted on business principles.

In England, Germany and France the gas engine has come into extensive use in isolated lighting, and already has been adopted with satisfactory results in several central stations of considerable size. When the business is properly handled in this country, we may expect to see the gas-engine make its way rapidly in the lighting industry here also, for it has merits which need only be known to be appreciated.

DISCUSSION.

Mr. Edgar—I would like to answer the questions Dr. Crocker raised; but before doing that, I desire to call attention to the point he made in regard to charging accumulators in series. He probably referred to the Popp system in Paris, which I also investigated with considerable interest. If that system is used, it is impossible to charge and discharge at the same time unless the local systems of distribution are entirely separate; so that it could not by any possibility be used as we use systems of distribution in this country. All our network is connected together, and if our batteries are to be charged in series, it would be necessary to have two entire sets. This seemed to me to be the principal drawback of the system there, and it prevented its extension. It is impossible to keep the circuits entirely free from grounds, and the results would be that one system would have one voltage as compared with the ground, and the next another, and the next another, and it might go up to two or three thousand volts.

---

*Abstracts of communications read at the 101st Meeting of the American Institute of Electrical Engineers, New York and Chicago, November 20, 1895.

In regard to the question he asked in respect to cost, I have not the slightest objection to giving exact figures which will show upon what I base my statement. Our first battery was put in to give out 1,650 amperes on each side of the system. A 650 horse-power generating set gives out 1,333 amperes on each side. This, as a steam plant, would have cost $65,000. Our contract was for $44,000, and there were enough incidentals probably to bring it up to $50,000. This included 45 per cent. duty. The second battery was double the size. That capacity would cost $130,000 if it had been a generating plant. Our contract was $64,000 for the battery. The former price included the switchboard, the latter did not; to that I add $25,000 to include switchboard and everything outside of the building. So that about $90,000 as compared with $130,000, and $50,000 as compared with $65,000 is the comparison I had in mind. I want to emphasize this one thing, and that is that we do not care anything about the kilowatt-hours of the battery for this particular comparison. Kilowatt hours have to do with operating. Kilowatt maximum has to do with investment, and we put it in for investment purposes. That is to say, as I have already said, we can with the same amount of capital put in more apparatus by using storage batteries than we can without. Now, if such apparatus has a capacity large enough to do that work which actually exists, we can actually save money by equipping one-third of our stations with battery and two-thirds with steam.

Now, in regard to efficiency, our guaranteed efficiency is 75 per cent. I never have understood that a high rate of charge and discharge was going to interfere with the efficiency of the battery. It is undoubtedly going to cut down the capacity. With an hour-and-a-half rate of discharge, the battery has only two-thirds of the capacity that it has at four, five and six hours discharge.

Then in regard also to the question of guarantee, I know nothing about what the American company guarantees. I have never asked the question. Our guarantee was for six per cent. of the cost of the cells. On the $44,000 contract I think the cells were put in at about $29,000. In the $64,000 contract the cells were put in at $59,000, so we are paying six per cent. on $59,000 worth of investment. There was a clause in the contract that if an American company was established this should be reduced to four per cent., because this was done in Germany.

Mr. H. Ward Leonard—There is one use for storage batteries which has not been touched upon particularly, and which to me is perhaps one of its best applications, and that is in connection with the regulation of the speed of the motor, such as would be required for the operation of, for instance, elevators or street cars, as giving an abundance of means of securing variable electromotive forces for various speeds and for reversals of direction. The point about storage batteries which is often raised to explain why the progress has been rather slow in this country has been the patent litigation, but I look upon that as merely an excuse for the slow development of an article which has not had a demand sufficient to develop it. I do not believe that any really meritorious article has been in the electrical field thus far which has been retarded in its progress by litigation, and the progress of the litigation which we have seen in the case of incandescent lamps, systems of distribution and electric street cars, while it may have cost a great deal of money for the litigants, as it unquestionably has, I do not think has tended to retard the progress of development—rather the reverse. In the case of storage batteries, the demand has not existed and their use has not given success, and that is the sole reason for the fact that they have not been used.

As regards the cost per kilowatt, which is very largely the essence of the question involving economy, it seems to me that the figures that I have seen quoted, which make a favorable showing for the storage battery, take the maximum rates of discharge for the batteries that it is deemed safe to operate them at, and have taken the horse-powers of the engine at one-quarter cut-off. Now I agree with Mr. Edgar that the question of development of power for the peak of the load is one which is largely independent of the economy of production as compared with that for a very large portion of the total load which is below the peak. But it seems to me that in making comparisons we should consider the cost of the horse-power of steam-generating machinery when operated at its maximum load, its maximum capacity, which will certainly be fifty per cent., without unduly straining any good boiler or engine above that for which it would have for the ordinary evaporations in the boiler, and a quarter cut-off in the engine; and I think that steam plants figured on that basis can unquestionably be installed for fifty dollars per kilowatt to-day, and ones which will be certainly more efficient in the production of a kilowatt than the development of a kilowatt by a storage battery, with the conversion losses and the lack of efficiency and capacity due to discharge at high rates. What I would like to find out, if we can, is: What is the cost per kilowatt when the battery is discharging at the rate for which the manufacturers guarantee the six or ten per cent. depreciation which they have guaranteed, and the figures—although we have had figures that are on their face very convincing—do not give to me an explanation of the difference between the prices which we have been familiar with in the purchase of batteries and those which have been quoted. I have bought batteries and installed them almost every year since 1885, and I have never succeeded yet in buying a battery at a price approximating $50 per kilowatt, although, of course, I have not dealt in very large units, but I have received a discount from the list which is as favorable as I think is given to customers in this country, because the instances that I had were ones in which the manufacturers were quite interested in seeing the applications made. I could not get the batteries at less than $180 per kilowatt when operated at the maximum rate at which they would make any guarantee. I think that, judging from the price lists that we have in this country, it is impossible to expect to get batteries to compare in cost with steam plants, even when run at double the rate that they call the excessive rate of discharge, that is, even allowing that the battery shall be run at double the excessive rate. The cost of batteries, even those of the largest size—if I may judge from the prices of batteries of smaller sizes—would be at least $100 per kilowatt.

I have been installing dynamos for a great many years, and I do not know one of them that I have installed that is not running perfectly successfully and economically to-day and in good condition. And, as I say, I have been installing batteries nearly every year also, and I do not know one battery that is running that I have installed. That may be because I installed it, but there may also be some influence due to the fact that it is a battery. One of the best remarks about a battery that I ever heard was made by Mr. Edison to me. He said that "the blamed thing was wet," and I think that expresses a great deal electrically.

I do not think that the storage battery is likely to be installed, when considering the question of cost, in the light in which I presented it, because of its economy over the steam plant in dollars and cents, but I do not think that that is the thing to be considered. I think that Mr. Edgar has expressed it very well, and we all of us know how it is of the utmost importance that the service from an electric central station shall be perfectly reliable and that the light shall be perfectly uniform, and the question of cost of the battery, to my mind, and its efficiency also, is quite of secondary importance—if by the use of the battery they obtain absolute reliability of service and perfect uniformity of the light, and cannot otherwise—and I think that the battery may be installed in a station with a net saving to the station, rather than to go without it, when viewed from this standpoint, while I do not believe in the actual saving in dollars and cents in our central stations in this country with the character of load diagrams that we have.

Mr. J. B. Entz—I have recently spent a year in the factory of the Tudor Company in Germany, and have had occasion to know what their practice is in that country and what their results have been. They have a great many large central stations which have been installed from ten to six years. The company sells the batteries with the capacity specified for the different rates of discharge. The customer may discharge it in one hour, two hours or ten hours as he pleases, and it does not affect the guarantee. The purchaser has the option of taking the battery without any payment for guarantee for two years. The company keeps it in perfect repair for that time. At the end of two years the purchaser can take a guarantee from the company for four per cent. a year for ten years, but very few of them care to do that. The actual expense of maintenance has been two and a quarter per cent. to the company. In that time they made considerable money out of that four per cent guarantee.

Mr. J. Appleton—There are one or two things about Mr. Perry's communication to which I would like to call your attention. He advocates the use of generators driven by gas engines for taking the peak of the load in central stations. Now in any station of a reasonable size this peak must be at least 400 horse power. In order to take this with gas engines, it must be necessary at least to have two or more engines driving generators. I would like to ask Mr. Perry if he has tried to run dynamos in parallel with gas engines of that size. If he tried it once, I do not think he would be inclined to advocate it in this way. I notice Mr. Perry begins his communication by advocating the use of gas engines for electric lighting, and then goes on to say that he does not think there is a single case in this country where they have been successful. I think this must be due to the fact that he has never tried to use them in conjunction with storage batteries. The modern gas engine, as built in this country to-day, I do not think is very far behind the European gas engine. Germany is considered the home of the gas engine, but I think we are getting nearly as good results in this country now as they are obtaining there. In fact, I know of many isolated plants which are working perfectly satisfactory with a combination of a gas engine and storage battery. Mr. Perry calls attention to the fact that in England, France and Germany a great many isolated plants and also central stations are using gas engines, but I venture to say that not five per cent. of the whole number are running without a storage battery in combination. Referring to his suggestion of transmitting power to outlying stations by means of gas through an iron pipe, even if the gas engine were available for taking the load in the outlying district during certain hours of the day, I think his calculations are wrong in one respect. He compares the price of the iron pipe to the price of copper mains. Now I take it that if he has his iron pipe he must have his copper mains as well; and having his copper mains he might just as well use them to transmit current to the outlying districts, and charge the storage battery, raising the pressure by a booster.

Mr. Chas. Blizard—We do not recognize the company Mr. Perry so mysteriously describes as "the leading storage-battery company of this country." Through an oversight, unintentional no doubt, Mr. Perry does not quote from a letter under date of June 11th, 1894, sent him by this same "leading storage battery company," in which the matter of maintenance is dealt with as follows:

"We will undertake to maintain installations of our accumulators when operated at normal rates, upon a basis that will limit the cost of perpetual maintenance to 10 per cent. per annum upon the original cost."

If Mr. Perry had brought his communication up to date, he might have quoted from the current edition of the catalogue issued by the storage battery company in question, in regard to maintenance, as follows:

"The company is prepared to undertake maintenance contracts under which they will guarantee that the total amount paid for renewals during the term of the contract shall not exceed 10 per cent. per annum on catalogue prices of the cells specified in the contract." The clause covering the return of the old material being omitted.

It is generally understood that retail prices are not maintained when wholesaling. It is not a fact that the public has been led to understand by the battery company or its representatives that the guarantee offered means anything more or less than what is distinctly stated in the catalogue, and the fact that in the letter from which Mr. Perry quotes he has referred to the catalogue for terms of guarantee is a sufficient refutation of his argument.

Mr. Perry's criticism would seem to cover the manufacturer who recommends the installation of a battery of capacity suitable to the work to be done, and who asks when giving a maintenance guarantee that the battery be worked within its normal limits and handled in accordance with the simple rules which experience has proven produce the best results as to efficiency and durability. I fail to see the injustice or hardship involved in these requirements.

Mr Perry's statement that the guarantee holds good when the battery is cared for in exact accordance with the instruction laid down by the manufacturer, conveys the impression that an infraction of the rules would necessarily nullify the guarantee. While the selling company would undoubtedly have the right to withdraw, I do not know of a case in which such a course has been taken. "The leading storage-battery company of this country" does not anticipate that its business will be materially affected by Mr. Perry's alleged discovery of the difference between its nominal and actual guarantees.

THE ELECTRIC WIRING QUESTION.*

BY FRED. BATHURST.

Having established the fact that, either from "excess of supply" or a "lack in demand," our contractors are face to face with a serious economic problem, it behoves us to look into our present methods of wiring to see in which direction economic improvement can be contemplated. Let us consider briefly the essential features of good wiring. The five cardinal points may be given as safety, durability, convenience, accessibility, and economy. Professor S. P. Thompson, in a lecture on the subject before the Society of Arts, embodied the essential features in a few words when he said, "What is wanted is a mode of running wires and fixing switches and other accessories, so that they shall not only be electric-tight, but shall also be water-tight, gas-tight, air-tight, oil-tight, fire-tight, and even rat-tight." The only "tight" he has omitted is "money-tight." It is my belief that all these requirements can be met by the use of *fire-proof insulating tubes*; but before dealing with this point I may be permitted to challenge the existing methods in the light of these requirements.

It will probably be admitted that wood casing fails in many respects. As a "mechanical" protection for the wires it is imperfect; and it is as deficient in "insulating" protection, because it is neither damp-proof nor incombustible. To again quote the words of the above-referred-to authority, it may also, like charity, "cover a multitude of sins." In concealed work it is positively an obstacle to the development of electric wiring.

Even on the surface, however, it is neither picturesque nor decorative. It is easy to install, but its nature prevents any very correct or exact estimate being formed of the labor required. If surface work is required, on the score of economy surely it would be better to adopt "open work" on porcelain insulators—a safe and scientific method of wiring, which can be carried out at a very much lower price.

"Insulation test" cannot discover an unsoldered joint or a dangerous diminution in respect to current-carrying capacity. Every practical man will agree that insulation testing will not necessarily indicate that the wires are at places in dangerous proximity to gas or water systems in event of moisture appearing. To continue, the recognized shortcomings of wood has brought into use iron and "lead compo" piping.

It may be thought that we must turn away from tube or pipe methods altogether in order to find economic wiring. Experience in other countries, however, does not show that any "rigid" system of conductors is making progress or headway. No insulated wire has yet been produced which in itself can successfully resist the deteriorating influences present in mortar or plaster. Even lead-covered insulating wires, if directly embedded in plaster, have been found wanting, and give trouble from "earths" and "short-circuits" as soon as moisture has made an appearance.

With any rigid method, if walls happen to crack and settle, or plasterers and bricklayers cause damage, a fault may develop which is very difficult to find. Usually, also, they are handicapped commercially in respect to making joints and connections, as these involve risk and trouble even with the highest quality workmen. A cardinal objection to "rigid" methods is the lack of accessibility. All good wiring should be accessible, for with this quality assured half the difficulty of "trouble" is already fought, and any imperfection or injury, whether arising from poor work, negligence or accident, can be remedied with a minimum of inconvenience.

A conduit or race-way is the practical way of rendering wires "accessible," for then the wires installed in them are always open to the inspection of owner or wireman whenever he wishes to satisfy himself as to their condition or to effect a renewal. "Accessibility" ought, therefore, to be a fire office requirement; with it an inspector can use his *eyes*, and have no need to trust to his *ears* for inspection.

From the contractor's point of view "accessibility" is desirable as limiting unfair and injurious competition; for, when an installation can be readily inspected, inferior materials cannot be used for the purpose of cutting down prices, workmanship cannot be scamped, and the "death knell" of unprincipled competition could be sounded for all time.

This brings us to the consideration of the conduit itself. From a labor-saving point of view a flexible conduit would apparently commend itself. Whilst cases do occur where this is true, every flexible conduit has the inherent drawback, as shown by experience, that the property of "flexibility" may so far assert itself that numberless bends will prevent the wires from being drawn out. Any trouble which then occurs will have to be cut out, or else the circuit must be abandoned or wired anew. Flexible conduits are always at a disadvantage either in respect to moisture-resisting properties or are wanting in mechanical strength. Bends and elbows must be *rigid*, or it is impossible to draw the wires in or out; and for the generality of work it will be found that a conduit construction permanently rigid throughout is preferable.

I have already pointed out that more than half of the wire we use is referable to "insulation," and that it is "insulation" we strive to keep. It would, therefore, appear obvious that the conduit should be an "insulating" one. An ideal insulating tube should not only be mechanically strong, but also fire-proof and water-proof. With a tube complying with these requirements all possible electrical trouble is minimized, the insulation on the conductors themselves is protected from mechanical damage, and is enveloped in a preservative rather than a destructive element. Temperature changes are reduced to a minimum, and, if the conduit resists acids, alkalies and gases, the insulating material on the wire is so shielded that its life is indefinitely prolonged. It appears to me that the insulating tube does for "wiring" what the high-resistance incandescent lamp did for the "distribution" problem. I contend, therefore, that an insulating tube method of wiring will prove the ultimate solution of the electric wiring question.

Accordingly, I have pleasure in showing a few samples of the insulating tubes manufactured by the Interior Conduit Company of New York, in the belief that they represent the highest achievement yet accomplished in the production of the ideal tube. This method of wiring originated with Mr. E. H. Johnson. This name, from its connection with the Edison companies, will be familiar to many. The system and process of manufacturing the tube and accessories have been worked out by Mr. Johnson in conjunction with Mr. Luther Steringer and Mr. E. T. Greenfield as co-patentees.

The system provides perfect immunity from fire, durability of insulation, accessibility to concealed wires, and reliable service. It has had extensive practical test in America, and more recently in Germany, where its reputation for being the safest, least expensive and most practical method of wiring is now established. Perhaps the best confirmation I can give of this statement is the fact that we already count, in various countries, some two million incandescent lamps installed in the three varieties of tube—"plain," "brass-covered," and "iron-armored"—and have yet to learn of the first electrical fire arising from its use. Risking the criticism of "advertising," perhaps the best course that I can take is to examine the system in regard to the five cardinal points before mentioned of safety, durability, convenience, accessibility and economy.

When deterioration does take place in a plain metal tube, the tube itself becomes a conductor, and invites deterioration at many points. If insulated tubes are used (with two conductors inside), the deterioration on one only brings additional stress upon the other conductor at one point. The tendency in this case is to create a "short-circuit" at the spot affected. In these particular tubes a short-circuit presents no danger, as the materials of which they are composed will resist the burning effect of the arc. Many tests have been made, and in every case it has been found that the "arc" increased in length until it broke, and severed the circuit without further danger. Any "short-circuit" trouble, then, removes itself, and its injurious effects are confined entirely within the tube. Since the presence of moisture is the principal cause of "short-circuit," the use of these tubes is likely to minimize the occurrence of trouble, because the tube material is non-conducting in respect to heat, and extraneous changes of temperature fail to produce internal condensation.

While on this question of safety, I should say that there is only one point not yet entirely settled. It is whether the two insulated conductors should be kept together or separated—whether one or two tubes should be employed. Owing to the real necessity with a wood-casing system of keeping the wires apart, some authorities urge that this construction should be applied to tube methods, and that a separate tube should be used for each wire.

---

*Abstract of paper read before London Institute of Electrical Engineers.

In alternating-current circuits it is essential to keep the wires close together, to prevent a drop in voltage from inductional effects. Clearly, therefore, in this case both wires should by preference be in the same tube. Since in England two conductors are already allowed in "compo" pipes, I do not here anticipate objection being made to this construction in respect of an insulating tube which is electrically perfect and equal to "compo" mechanically. Moreover, in those positions where mechanical strength is imperative the insulating tube can be supplemented by an iron or steel covering. I maintain that theory points to the advisability of placing both wires together, and so far the results of practice favor this view.

As far as present experience has gone, it shows that the bituminized tube will, under ordinary conditions, last indefinitely. It can safely be embedded in the lime and sand plaster used in ordinary building construction. I may mention that the present tendency towards fire-proof building construction is bringing into use certain cements, caustic enough to attack nearly any material coming into contact with them. The problem thus presented has been successfully solved by the introduction of the "brass-covered" insulating tube.

The bituminous material used in these insulating tubes is inert in its nature, and exercises no deleterious influence on the insulating material of the wires themselves. It has sufficient mechanical strength to resist any damage except that inflicted by gross carelessness or design, and in the case of chance mechanical injury to the tube the "accessibility" it provides renders repair easy. In respect of permanence and durability, the advantage of placing the conducting wires in channels which predetermine their relation to any contiguous conducting bodies is, I think, beyond question.

A perfect system of wiring should not only give a suitable channel for the wires, but must provide for the convenient jointing of the tubes themselves, and also for "switch" and "lamp" outlets. It should admit of the multiplication of small circuits from convenient "centers of distribution," as this construction avoids the necessity of joints in the wire, and permits equalization of the voltage throughout the whole installation. An architect ought to be able to lay out the system and provide in his plans for the electrical installation as completely and intelligently as he now provides for steam or gas utilization. The system I advocate satisfies these requirements, for after the conduits have been erected and all danger from mechanical injury has passed, the wires can be readily drawn into their respective channels, and connected up to suitable distributing blocks. There are numbers of existing installations where over 1,000 lamps are in use, and in which any wire is "accessible" at any moment.

An insulating tube system is also economical. With trained workmen, we estimate saving from 25 to 50 per cent. in the labor of installation. Even though the tube in itself is comparatively expensive, if wires suitable to it are employed, the total cost of material will compare favorably with any other system.

The insulating properties of these tubes is such as to provide (approximately) an additional "300 megohms per mile" insulation resistance to the wire. We are beginning to appreciate the fact that, although we provide a costly "600-megohm wire," after having installed a few hundred feet our tests indicate a total insulation resistance of only a few thousand ohms. An insulating tube system can assist us to obtain a more commensurable result. If a high insulation test has to be obtained in wiring work, practical experience shows there is little doubt that an insulating tube, and its suitably insulated wire inside, is commercially ahead of a relatively heavily insulated wire.

Perhaps the limit of economy will be reached when we know how to "earth" perfectly, and can use a bare copper conductor within a metal-covered insulating tube.

THE CROMPTON POTENTIOMETER.

W. C. Fisher has concluded in a recent number of *The Electrician*, London, a series of articles describing the Crompton form of potentiometer and the uses to which it may be adapted by central-station engineers and others.

Describing the instrument as briefly as possible, it might be said to consist in its present form of 15 sections of wire connected in series, 14 of which are in form of coils concealed in the instrument, the 15th being stretched along a scale suitably divided; all are accurately adjusted with each other, so that with a fixed E. M. F. of 15 volts over the whole each section has a fall of $\frac{1}{10}$th of a volt, the scale beneath the slide wire being divided into 1,000 parts, each part corresponding to $\frac{1}{10000}$th of a volt (see Fig. 1).

The unknown quantity x to be measured is placed in series with a galvanometer G and attached to the movable contacts A and B, the intermediate reading between the contacts or main sections of A being obtained by the movement of B along the slide or scale wire, x being so connected up that its E. M. F. opposes that of the main circuit. No deflection of the galvanometer takes place when the point of balance between the opposing E. M. F.'S is obtained; such position, supposing it to exist in the diagram given, would be represented by the contacts 4 and 500 divisions of the scale wire, which, taking into account that each section is equal to $\frac{1}{10}$th of a volt, is equal to 0.450 volt. This represents the ordinary working conditions of the main instrument when used in measuring E. M. F. or current. Under certain circumstances, more especially when measuring resistances, it is advisable to alter the main E. M. F., in which case the values of the sections are correspondingly altered; such conditions will be described as they arise in the study of the capabilities of the instrument.

Although the above represents roughly the diagram of the main instrument, there are fitted in it certain switches and a rheostat for adding resistance in the main current, so reducing the E. M. F. of the secondary cell ordinarily used to the proper value, and for connecting any series of x into circuit in due rotation, so that measurement may rapidly be taken in sequence, there being also a short-circuit key for the galvanometer and a due array of necessary terminals, the true diagram of the instrument therefore being that shown in Fig. 2.

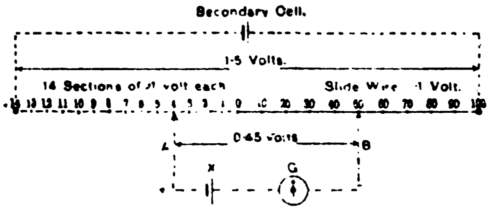

FIG. 1.

In using the instrument for the measurement of power, the first operation necessary is its due calibration—i. e., the adjustment of 1.5 volts at the terminals of the whole of the sections; for as shown in the diagram, a secondary is used as the source of main E. M. F., and having, roughly speaking, an E. M. F. of 2 volts, resistance has to be inserted in circuit to bring it down to the 1.5 volts required. This value is ascertained by substituting for x a known value or standard—i. e., a Clark's standard cell; its temperature is noted, and the two points A and B are placed upon the figures corresponding to the value of the cell at that temperature. Resistance is added in the main circuit until there is no deflection of the galvanometer, due to the fact of the two E. M. F.'S—that in the main and galvanometer circuits—equalling one another; the instrument is thus standardized from what afterwards becomes the x circuit, and is then ready for working and obtaining the value of unknown E. M. F'S. The act of switching in the unknown puts the standard cell out of circuit, so that no possible accident can happen to it, and it need only be brought into circuit again for occasional check purposes.

It will be noticed that the maximum observed E. M. F. on the potentiometer is 1.5 volts; all values therefore to be measured must fall within that range. To meet this requirement multiples and submultiples of the ohm are used, and are so proportioned that their maximum carrying capacity is some definite value proportional to that of the instrument and it is entirely upon them that the range of the set of apparatus depends, the maximum standards made up to the present being for the measurement of 10,000 amperes on the one hand, and 3,000 volts upon the other, but this does not in any way suggest the limit, which might almost be described, in the case of current, as illimitable, whilst with voltage the question of insulation alone steps in.

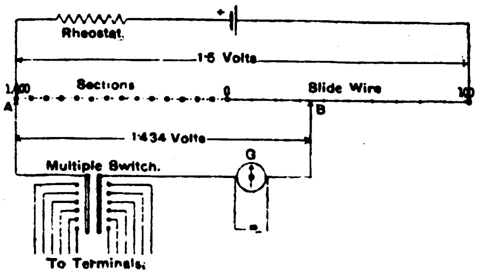

FIG. 2.

Taking, first, the question of the measurement of current, this is done by passing the current to be measured through a standard low resistance of such value that the fall in volts with maximum current over the whole does not exceed that measurable on the potentiometer. The usual units adopted by the majority of the English central stations allow of standards for maximum currents of 1,500, 750, 150, 15 and 1.5—the last three for meter and lamp testing, the preceding two for machine and instrument tests. To be effectively used with the instrument described they should be so proportioned as to be direct reading—that is to say, the first, with a load of 1,500 amperes, should allow of a fall of 1.5 volts. Each section of the instrument having $\frac{1}{10}$th of a volt, will therefore correspond to 100 amperes, each division on the scale to 0.1 of an ampere; the second standard should be similarly proportioned, 750 amperes reading at 0.750 volt; the third standard, for 150 amperes, should have 10 amperes per second and 0.01 per division of scale; the fourth, for 15 amperes, having 1 ampere per section and 0.001 per division; the fifth, for 1.5 amperes, having 0.1 per section and 0.0001 per division. If, therefore, any of these standards are placed in the circuit, current through which is to be measured, the fall of E. M. F. over same is balanced on the potentiometer, and value in current read off accordingly direct.

The maximum E. M. F. ordinarily measurable on the potentiometer is 1.5 volts, but for secondary cell tests, etc., it may be made 3 volts by adding another secondary, and balancing with the Clark cell at half value, but in that and other cases in which it may be done it is necessary to multiply the reading by 2 to obtain the true result. When, however, some very much higher E. M. F. has to be measured, it is necessary to place it across a very high resistance, the fall over some portion of which only is measured. For instance, taking a box of 100,000 ohms, across which is placed 1,000 volts, the fall over 100 ohms corresponding to $\frac{1}{1000}$th of the total, and represented by 1 volt only, is carried to the potentiometer; in the same manner, if it were 100 volts, the fall over 1,000 ohms, or $\frac{1}{100}$th of the whole = 1 volt, is connected; or again, if 10 volts, that over 10,000 ohms, or $\frac{1}{10}$th of the total, still 1 volt only is taken to the instrument. The instrument is, therefore, direct reading, unless, as in the case of current measurement, half values are taken and the reading doubled—a practice equally bad in this case, and for the same reasons, therefore, to be avoided.

In the standards supplied for current and E. M. F. measurement we have accurate submultiples of the ohm—i. e., $\frac{1}{1000}$th, $\frac{1}{100}$th, $\frac{1}{10}$th of the ohm, and also multiples of 100, 1,000, 10,000 and 100,000 ohms, the missing 10 ohms to complete the series being easily obtainable with these. It is therefore possible to measure from the infinitesimal part of an ohm to many megohms, in the following manner:

The unknown is placed in series with the standard with which it is to be compared; a current suitably adjusted is passed through both, the E. M. F. at the terminals of the standard being duly connected with x and balanced at any point most suitable on the instrument; the E. M. F. at the ends of the unknown is then brought into instrument circuit at x, and its value compared with that of the standard.

In conductivity tests the procedure is, of course, the same as that pursued in measurement of resistances. The sample strip, wire, cable, or sheet is placed in series with the standard considered most suitable, and its resistance ascertained as accurately as possible; this is duly compared with that calculated in the usual way, from its known length, section, weight, etc., and the percentage conductivity at given temperature ascertained. This, however, is not necessary, if comparison is made with a known copper standard, duly protected from atmospheric influences and injury, in which case the conductivity may be read off direct, which is very much more simple and occupies less time.

To the measurement of temperatures by means of the platinum thermometer the potentiometer lends itself well by reason of its flexibility and range, and the total disregard of resistance of leads and consequent compensation. Whether it be ordinary atmospheric changes of temperature, or those produced by friction or intense heat, from the melting point of ice to that of the platinum wire itself, all comes easily within the range of the instrument; therefore, by its means temperatures of liquids, flue gases, hot bearings and journals or of the atmosphere may easily be measured in the following manner: The platinum spiral is placed in series with a battery and standard resistance (which may be simple, compound, or compensating) having a temperature coefficient known or practically negligible. This standard is equal in resistance to the pyrometer when at the temperature of melting ice; when, therefore, placed in circuit, as described, and balanced at any point of the potentiometer, any change in the resistance of the platinum spiral is at once detected by comparison, assuming it to be caused by temperature. Such temperature may be measured by means of the constant supplied with the thermometer, and which may be practically taken as 0.38 per cent. per degree Centigrade, which, divided into the difference between the balance of standard and spiral, gives the actual temperature in degrees Centigrade.

SOME NOTABLE ISOLATED ELECTRIC LIGHTING PLANTS.

Private installations of electrical generating apparatus for purposes of lighting and power have become so general that any addition to the already large number of isolated plants must have the merit of novelty to attract any particular attention from persons interested in the art.

The installations described and illustrated in these pages quite properly come under the classification just made. Aside from the interest attaching to a description of any particular department or feature of the most palatial hostelry or one of the greatest churches of a great city, the data which follows will invite attention from all those who have given any thought or study to the problem of safely, efficiently and economically lighting large buildings.

The Hoffman House has long been one of the chief objects of interest in New York City for both the traveller and the native. The magnificence of its equipment and furnishings, even in its earlier days, brought to it the well-merited distinction of "the finest in the city." In 1894 the hotel was reconstructed on a scale of magnificence surpassing all previous efforts in the history of hotel equipment in this country, and during the past year an extension fronting on 25th street and Broadway has been added, the completed structure now forming the New Hoffman House.

THE NEW HOFFMAN HOUSE.

The electrical equipment of the hotel consists of two generating plants. The first of these supplies current for use in the main part of the hotel, the second for the addition, although the arrangement is such that the plants can be used interchangeably, or one can be used for lighting the entire building. The earlier plant installed consists of two 50 K. W. and one 75 K. W. 110 volt General Electric generators direct connected respectively to 75 and 125 H. P. Ball & Wood engines. Steam is supplied by four horizontal tubular boilers of 125 H. P. capacity each. Exhaust steam is used in the heating service of the building.

During the past year there has been added a second plant, located on the Broadway side of the basement. The equipment consists of one 1,500 light "Wood" type alternator, built by the Fort Wayne Electric Corporation. The generator is compound wound, separately excited by an exciter driven by belt from the main armature shaft, and delivers current to the switchboard at 100 volts potential without the intermediary of transformers. The switchboard is of marbleized slate and is equipped with Wood measuring instruments and huge double-throw double-pole switches. By means of these switches either generating plant can be thrown into service or the load divided between the two if run simultaneously.

The prime mover in this plant is a High Speed Buckeye engine built by the Buckeye Engine Company, Salem, Ohio. The cylinder is 16¼ inches in diameter and 18 inches stroke. The engine is speeded at 225 revolutions per minute; this under 90 pounds steam pressure gives a rating of 200 H. P. The generator is belted to the band wheel of the engine by a perforated leather belt.

The building of the extension to the hotel has necessitated a reconstruction of the main system of current distribution installed when the first plant was built. In addition to the multiple connection of the switchboards of the two generating plants the mains are taken to a common distributing center. A distributing board of slate, constructed and erected like a switchboard and equipped with necessary switches, controls the supply of current from either generating plant and its distribution to the several circuits. Arrangements are also made to connect the system with the street mains should an emergency arise.

Throughout the completed building 2,800 16 C. P. lamps have been wired. The generating capacity, as will be observed, is sufficient to operate 3,800 lamps. Excepting the distributing mains leading from the switchboards to the distributing board and which are suspended from the ceiling by porcelain insulators, the wiring is incased in iron-armored conduit made by the Interior Conduit & Insulation Company. On the circuits used for decorative illuminations brass-armored conduit has been used. Bishop and "Safety" wires have been used.

Alfred Zucker of New York was the architect and Hatzel & Buehler, 114 Fifth avenue, New York, the electrical contractors for the extension now being completed. The earlier electrical equipment was installed by the New York Electrical Equipment Company. John J. Hackett is electrician in charge of the entire electrical equipment of the hotel.

The lighting and power plant of Grace Chapel and Mission Buildings is another installation possessing several features of novelty. The group of buildings which are to be set aside for the missionary care of the poor of the East Side are located on East 14th street, occupying a rectangular lot 200 x 125 feet. The buildings comprise a main auditorium, morning chapel, hospital, clergy house and parish house. The auditorium has a seating capacity of 800. The small chapel will be used for early morning services and will be kept open all day. The hospital will be devoted to the care of the aged poor and homeless children. The resident clergy will be housed in the clergy house while in the parish house provision is made for a boys' school, a cooking school, sewing-schools, a boys' club, etc.

The electrical generating plant of these buildings is located in the basement of the clergy house, fronting on 13th street. The space set aside as a dynamo room is somewhat cramped, the aim having been to reserve as much space as possible for gymnasium and swimming bath, both of which are located on the basement floor. Scant as the floor space may be, the design shows how compactly a plant of this size can be arranged. The electrical equipment consists of three generators, one 50 K. W. and one 25 K. W., 125 volt, for the lighting service, and one 50 K. W., 250 volt, for power service. The generators are of the Mather type, multipolar, compound wound and connected direct to Armington & Sims engines. The engines driving the 50 K. W. generators have cylinders 13″ x 12″ and run at a speed of 275 revolutions per minute. The engine for the 25 K. W. generator has cylinders 9½″ x 12″ and runs at a speed of 300 revolutions per minute.

The dynamo leads are carried to an Italian marble switchboard, at one side of the engine room, upon which are mounted the generator field rheostats, Weston illuminated dial measuring and indicating instruments and the knife-switches for the control of the main and feeder light and power circuits.

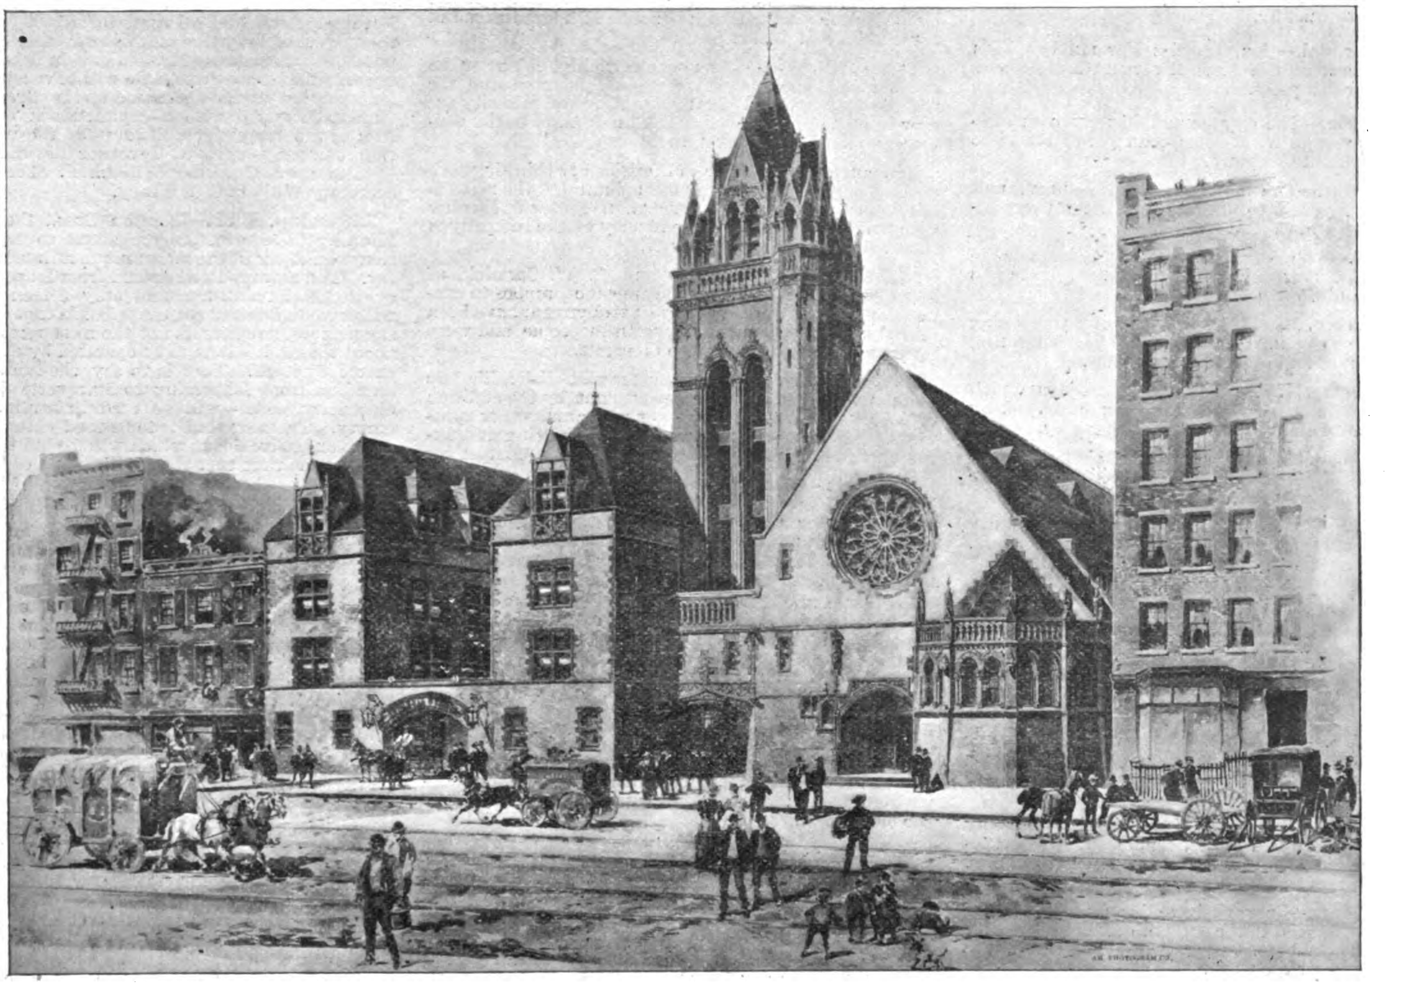
The wiring of the buildings is installed on the conduit system throughout, brass and iron armored interior conduit being used. Feeders are run to the distribution centers, connections to supply conductors being made through cutouts of the panel-board type, of a special design, mounted on slate panels and enclosed in slate boxes. These boards are all located at convenient and accessible points. Bishop rubber cored wire is used throughout the buildings, which are wired for approximately 12,000 16 C. P. lamps. The power service is separate from the lighting service. When the equipment is fully completed, two elevators, two Sturtevant ventilating blowers, the organ and the chimes will be operated by electric motors. For the elevator, two 20 H. P. motors will be required; for the ventilating fans, one 10 H. P. and one 5 H. P., and for operating the organ bellows one 1 H. P.

In the location and distribution of lamps in the auditoriums of the main chapel and the morning chapel the aim has been to secure a uniform degree of illumination and subdued effects. Wherever possible the lamps have been concealed. In the main chapel the chancel is lighted by vertical rows of lamps placed behind the supporting columns. From the auditorium the lamps themselves are not visible, but the reflected light given by them is very pleasing in its effects. The arch over the chancel in the morning chapel is treated in the same manner. Around the cornice of the cruciform auditorium of the main chapel, twenty-eight feet above the floor, is placed a row of lamps one foot apart. Alternate lamps are attached to separate circuits controlled by automatic switches located in the sexton's office, by means of which half or all of the lamps may be lighted extinguished as may be desired. Elsewhere in the building lamps are attached to brackets, or pendant from the ceiling, all electrically controlled by flush double-pole switches.

Every detail of the installation has been carefully worked out, making of the whole a complete plant of the most modern type, which has been installed in the best possible manner.

J. Stewart Barney and Henry Otis Chapman were architects of the buildings. Pattison Brothers, 136 Liberty street, New York, were the consulting engineers who designed and supervised the complete electrical equipment.

Hatzel & Buehler, 114 Fifth avenue, were the electrical contractors who installed the electrical plant and all its accessories.



GRACE CHURCH CHAPEL AND MISSION BUILDING.

Attractive Carbon Advertising.

Carbon products, such as motor brushes, battery carbons, electric light carbons, etc., have never been regarded as altogether proper subjects for artistic treatment. The advertisement of the Phœnix Carbon Manufacturing Company, St. Louis, Mo., published elsewhere in this issue shows that the possibilities in this line have not been overlooked by this progressive and enterprising western firm. This company has recently increased its capital stock to $250,000 which will be applied to increasing manufacturing facilities, so as to better accomodate the rapidly growing trade.

ARTISTIC ADVERTISING.

The trade-paper publisher often hears the complaint from manufacturers and merchants that advertising in trade papers does not pay. No one disputes the general proposition that advertising does pay, but each one makes his own defence for his position as to trade-paper advertising, and the usual story is: "My business, you know, is different; we can't offer bargains; nothing but personal solicitation will sell my goods."

There is some truth in this, also some error. In these days of sharp competition, personal solicitation and plenty of it is required to sell goods. But what salesman ever went on the road and made a successful trip for an unknown house or an unknown article of merchandise?

Personal solicitation is all right, and so is advertising when properly done.

If any concern in this or any other trade has found trade-paper advertising unprofitable, the fault nine times out of ten lies with the man who has charge of placing and preparing the advertising. A slovenly prepared advertisement may easily fail to do any good—even more, it is likely to do actual harm. But when a concern's advertising department receives proper attention—the same as is bestowed on other departments—advertising is a sure advantage, and a surely profitable investment. There is no line of merchandise which cannot, in some way, be profitably advertised. And in this trade, as in every other, those who devote thought and care to their advertisements grow in prestige and wax wealthy.

These remarks are called forth by the appearance of new advertising matter from one of the largest supply houses in the country—also one of the youngest. Starting in a conservative way only two or three years ago, this concern has worked steadily upward and has secured a business of mammoth proportions. Artistic advertising has not done all this, but it has been a potent factor. Followed up by persevering salesmen, it has done the business.

Does advertising pay? What man turning the pages of ELECTRICITY, feasting his eyes on the artistic production put forth to call attention to their new catalogue, will ever forget the Metropolitan Electric Company of Chicago?

GENERAL NEWS.

What is Going On in the Electrical World.

Kingston, N. Y.—The council has granted a franchise to the Rondout & Eddyville Electric Railway Company.

Beeville, Tex.—George W. Greathouse has organized a company here to erect an electric light plant.

Philadelphia.—The common council has declared in favor of establishing a municipal lighting plant.

Tarrytown, N. Y.—A. J. Mackay has applied to the trustees for the right to build and operate a trolley railway in this village.

Alexandria, La.—The electric light plant of the city is to be doubled. Additional dynamos, boilers, engines, etc., will be put in.

San Jose, Cal.—The board of trade has passed a resolution in favor of establishing a municipal electric lighting plant in this city.

Gainesville, Fla.—J. M. Graham, H. E. Taylor and F. W. Cole have petitioned the city council for an electric light plant franchise.

Los Angeles, Cal.—Gen. Charles Forman has been elected president of the Kern River and Los Angeles Electric Power Company.

Lake City, Fla.—The city council has given an electric light charter to W. R. Bush, manager of the Lake City Water & Light Company.

Ridgway, Ont.—The Crystal Beach Improvement Company has decided to build an electric railway between Ridgway and Crystal Beach.

Tully, N. Y.—An electric light plant is to be added to the waterworks, now nearly completed. A vote was taken on the addition on the 21st inst.

Benton Harbor, Mich.—Preliminary steps are being taken by the city council to secure an electric lighting plant to be owned and operated by the city.

Chatham Centre, N. Y.—The electric light plant which supplied this village with light has been destroyed by fire. The plant belonged to Henry C. Spangler.

Elyria, O.—Cars began to run on schedule time on the Cleveland and Elyria electric line on the 15th inst. The running time between the two places is 1½ hours.

Lincoln, Ill.—The organization of the Logan County Electric Light Company is announced. Capt. D. H. Harts is the president and the capital stock is $10,000.

Raleigh, N. C.—J. M. Tufts, of Boston, is building an electric railway to his new winter settlement, "Pinehurst," and will, it is said, extend it to Jackson Springs.

Unionville, Mo.—Bids for the erection of an electric light plant to cost not more than $18,000 will be opened January 10. G. H. Gardner, city clerk, can be addressed.

Newark, N. J.—An ordinance to prevent the carrying for toll of any freight, merchandise or express matter by trolley roads in this city has been introduced in the board of works.

Waycross, Ga.—The Satilla Manufacturing Company of Waycross wants a 1000-light incandescent dynamo, 50-light arc dynamo, 150 H. P. engine, and two 60 to 80 H. P. boilers, new or second hand.

Holyoke, Mass.—Surveys have been made for the proposed electric road to the summit of MountTom, and those interested in the scheme are awaiting a report as to the estimates for the work.

Moodus, Conn.—The people of this place are talking of plans to raise sufficient capital to build the Moodus, Marlborough and Glastonbury electric road, which was chartered as far back as 1893.

Ellsworth, Me.—Hon. George E. Macomber, of Augusta, has made a proposition to build an electric railway between this city and Ellsworth Falls, and will probably be granted a franchise.

Ennis, Tex.—It is reported that President E. H. R. Green of the Texas Midland Railway has an expert figuring on the practicability and probable cost of running trains on his road by electricity.

Wheeling, W. Va.—The Wheeling & Moundsville street railway was opened for traffic a few days ago. The road extends from Wheeling twelve miles south, to Moundsville, and was built at a cost of $200,000.

Chicago.—A representative of the Electric Storage Battery Company of Philadelphia has, it is said, completed arrangements with a South Side street railway company to run storage battery cars on its lines.

Montreal, Can.—The shareholders of the Montmorenci Light & Power Company have decided to accept the offer of the Electric Street Railway Company for the purchase of the stock and franchise of the former company.

New Albany, Ind.—It is reported that a syndicate of Eastern capitalists are negotiating for the purchase of the New Albany and Paoli turnpike with a view of building an electric railway between this city and Paoli.

Warren, N. Y.—The people of this town are anxious to have an electric road from Sugar Grove to Warren and are willing to subscribe liberally toward the undertaking. It is hoped to interest outside capitalists in the project.

Waltham, Mass.—The special committee on municipal lighting has reported to the board of aldermen in favor of the city purchasing the gas and electric light plant, which they valued at $253,000. The report was accepted.

Staunton, Va.—The street railway system in this city is to be changed at once from mule power to electricity. President D. D. Parmely of the railway company says the line is to be extended so as to make it a belt line around the city.

Columbia, Tenn.—Under a court decree the electric light plant and other properties of the Columbia Water Company and Columbia Improvement Company will be sold at public outcry at the court house here on the 15th of February next.

Redlands, Cal.—The Redlands Electric Light & Power Company has sold to Henry Fisher of Pittsburg, Pa., about $45,000 worth of bonds, which closes out all of the unsold bonds, and gives the company sufficient cash to pay off its floating debt.

Winona, Minn.—Right of way is now being secured for the projected electric railway from La Crosse to Neillsville. A slight change has been made in the route. by which the road will run through Mindora instead of three miles east of that place.

Tomahawk, Wis.—The new electric light plant at the dam on Tomahawk river has been completed and the wheels set in motion. Many buildings in this city are now lighted from this source. The distance to the generating plant is over two miles.

Buchanan, Mich.—The authorities are thinking seriously of buying the electric light plant and the right to 500 horse power of the Buchanan Power & Electric Company for $30,000. The property of the company is to be sold at auction January 17.

Suffolk, Va.—L. D. Smith and A. W. Cormick, of Norfolk, representing a syndicate who propose to connect Suffolk and Smithfield by a trolley road, have been over the ground, consulting with the people, and were favorably impressed with the prospects.

Newburgh, N. Y.—The Buttermilk Falls Electric Company intends to increase its plant by the addition of a 75 K. W. Westinghouse generator and other apparatus. All necessary wiring, pulleys, shafting and fixtures will be supplied by the Hyer-Sheehan Company.

St. Louis.—Work is progressing rapidly on the St, Louis and Kirkwood Electric Railway, known as the Houseman Air Line. The tracks are laid from the eastern terminus of the road, at the southwest corner of Forest Park, to Meramec Highlands, the western terminus.

Washington, D. C.—In the Senate a bill has been introduced to amend the charter of the Eckington & Soldiers' Home Railway Company, and providing for a new route. The bill provides that overhead wires shall not be used if electricity is the motive power and prohibits the use of horses.

Buffalo, N. Y.—The mayor has signed the ordinance giving the Niagara Falls Power Company a franchise to supply electricity for light and power in this city.—The new street railway company is encountering strong opposition to its proposed lines from those interested in the old companies.

Albany, N. Y.—The mayor has vetoed the electric light ordinance recently passed by the common council, one of his principal objections being that it was apparently framed to prevent competition by specifying a system to be used which is not up to the latest improvements in lighting.

Middletown, N. Y.—Bids will be received for additional lighting at the Middletown State Homeopathic Hospital, Middletown, N. Y., up to noon January 4, 1896. Specifications may be seen at the office of the hospital, and at the office of the State Commission in Lunacy, Albany, N. Y.

Rochester, N. Y.—Several new trolley lines are projected for next summer, to make the pleasure resorts in this section more easily accessible to our citizens. One of the most important of the proposed lines is the Irondequoit & Lake Shore road which will connect Summerville and Forest Lawn.

Baltimore.—The sale of the Baxter Electric Motor Company's property to Benjamin Deford and Jesse Hilles has been judicially ratified. It is understood that the company will not be reorganized, but the property will either be sold to an outside corporation or the plant and real estate disposed of separately.

Lorain, O.—An effort is being made to secure the location of a big electric motor works in this city, which will employ 325 men. Johnstown is also trying to secure the enterprise, but the chances are largely in Lorain's favor. Tom L. Johnson and his brother, Albert Johnson, are said to be interested in the motor works.

Macon, Ga.—Three hundred electric lights will be put in the Brown House at Macon. Every room in the hotel will be lighted by electricity. It is said that the Central Railroad, Brown House and one or two other neighboring parties contemplate jointly establishing their own dynamos to furnish electric light and power.

Niagara Falls.—The Niagara Light & Power Company will shortly begin the work of laying the wires for electrical transmission of power to Buffalo. The great transforming station will be at Tonawanda, to which point the current will be carried in large units, and from there distributed throughout Tonawanda and to Buffalo.

Crawfordsville, Ind.—Master in Chancery W. P. Fishback has sold at public auction the plant of the Crawfordsville Water and Light Company. William Hord and Newman Erb, representing the first mortgage bondholders, bid the plant in for $50,000. The plant is said to be worth $250,000, and has an indebtedness of $350,000.

Oswego, N. Y.—F. E. Pritchard, superintendent of the Oswego Street Railway, has succeeded in perfecting an automatic regulator for controlling the current which supplies arc lamps, preventing irregularity in the brilliancy of the lights. Mr. Pritchard is the inventor of a similar device for regulating the current on street car circuits.

Culpeper, Va.—There is some talk here of building an electric passenger and freight railway from this town to Front Royal. This would make a line through the richest part of Rappahannock County, and would be very helpful to the people of the county, as they have no railroad at all, and all freight must be hauled from ten to twenty-five miles to a depot.

Brooklyn, N. Y.—The rights, franchises and properties of the Long Island Traction Company, sold at auction recently to John G. Jenkins, president of the First National Bank of Brooklyn, for $5,000,000, were long the subject of litigation in this and other States. The purchase was made by Mr. Jenkins in behalf of the reorganization committee, who will have a new company incorporated under the name of the Brooklyn Rapid Transit Company with a capital stock of $20,000,000. Among the largest stockholders of the wrecked Traction Company were ex-Governor Roswell P. Flower, ex-Lieutenant-Governor William F. Sheehan and ex-Secretary William C. Whitney.

Ishpeming, Mich.—Winston Bros., the well-known Minneapolis contractors, are about to begin the construction of one of the most unique railroads in the country. The new road will extend from Ishpeming to Marquette, Mich., a distance of only fifteen miles, but it will have to descend some 800 feet in that distance. The steep grade, however, is not the most remarkable thing about the road. It is to be operated by electricity generated by itself. That is to say, the loaded trains descending from Ishpeming to Marquette will generate electricity, which will be used in hauling them back empty. The new road is to be used chiefly for hauling ore to extensive docks which will be built at Marquette at the same time that the road is being constructed.

Pittsburg, Pa.—A party of New York, New Haven and Hartford Railroad officials, headed by President Charles P. Clarke, visited the East Pittsburg works of the Westinghouse Electric & Manufacturing Company on Tuesday of last week. There they were shown the new polyphase long distance current system in operation. They also made a minute examination of the mechanism of the large motor engines which the Westinghouse Company and Baldwin Locomotive Works, of Philadelphia, are jointly experimenting upon, and which is designed for longer distance and heavier hauling than the motor engines now in use. None of the gentlemen would say whether there is any immediate probability of changing the motive power of their road. They said they are anxiously waiting the progress of the experiments with a view of taking the earliest advantage of successful results.

TELEPHONE AND TELEGRAPH.

Good Work in the Southwest.

F. H. Brown, of Emporia, Kan., has been active in extending independent telephone service in Kansas and Missouri. In a recent interview he said: "Girard, Pittsburg, Galena, Independence, Neodesha, Coffeyville and other Kansas towns have telephone plants, and I am now busy on plants in Parsons and Oswego. The cities are to be connected. In Missouri, there are Joplin, Carthage, Webb City, Carterville and Lamar. The cost to subscribers varies from $12 to $30. My charges at Parsons are $24 and $12; at Girard $24 and $30. In Joplin aad Carthage subscribers pay $30 and $18."

Another Pacific Cable.

The Pacific Cable Company has been incorporated at Trenton, N. J., with a total capital stock of $1,000,000, divided into 10,000 shares. The names of the incorporators are: Abram S. Hewitt, D. O. Mills, G. M. Dodge, Fred D. Grant and Wager Swayne, of New York; James J. Hill, of St. Paul, Minn., Z. S. Spaulding, of San Francisco; John H. Browning, of Tenafly, N. J., and Mason W. Tyler, Plainfield, N. J.

The object of the corporation is stated in the papers filed to be the construction and operation of electric submarine cables in the Pacific Ocean with telegraph lines and connections for the transmission of messages. Connection, it is understood, will be made with the Hawaiian Islands. Offices are to be maintained in Jersey City and San Francisco, and business will be commenced on January 1 next. The company has been organized through the efforts of Col. Spaulding, of Hawaii, who has obtained a concession for a cable to the United States, with an annual subsidy of $40,000 from the Hawaiian Government.

Called a Liar by Wire.

Rev. I. C. Monson, of Stevens Point, Wis., has brought suit against H. A. Lathrop and the Western Union Telegraph Company for $5,000 damages for an alleged libelous telegram sent over the Western Union lines by Lathrop in which Mr. Monson was declared to be "an unscrupulous liar."

W. F. Churchman, the receiver of the Phœnix National Telephone and Construction Company of Indianapolis, Ind., has filed his final report, showing that a syndicate was ready to purchase the property of the defendant, and that all creditors had been satisfied. The report has been approved and the receiver discharged.

The council of East St. Louis, Ill., has passed an ordinance providing for the construction of a night watch and messenger system. The Missouri District Telegraph and Night Signal Service Company has accepted the ordinance and will proceed with the construction of the system.

The Wausau and Merrill Telephone Company has let a contract to Peter Berard, of Merrill, to build a toll line between Wausau and Merrill, Wis. The contract calls for the completion of the line within thirty days, and the line will be owned jointly by Wausau and Merrill companies.

At the recent meeting of the stockholders of the Lansing Telephone Exchange, Lansing, Mich., the following directors were elected: J. Stahl, John Herrmann, W. A. Fraser, D. A. Reynolds, F. B. Johnson, Dr. Ranney, H. C. Hedges, L. C. Blood, H. K. Vedder and A. A. Nichols. The exchange now numbers 367 subscribers.

A sub-committee of the Electrical Committee of the Philadelphia city council is considering the application of the Standard Telephone Company for a franchise in that city.

The Fort Valley and Perry Telephone Company of Fort Valley, Ga., has declared a dividend of 24 per cent. on the capital stock. The company has been doing business but little over three months.

The ordinance adopted by the common council of West Bay City, Mich., for the Harrison Telephone Company has not been accepted by the company, and the $200 check that was deposited becomes the property of the city through limitation.

The Telephone Users' Association of Milwaukee, Wis., has secured new schedules of rates from the Wisconsin Telephone Company, granting material concessions, to take effect January 1.

Mayor Lebknecher, of Newark, N. J., is withholding his signature from the ordinance granting rights to the Home Telephone Company of that city. The company announces its readiness to go ahead as soon as the ordinance is signed.

A new copper wire is to be strung by the Western Union Telegraph Company between Albany and Pittsfield for the exclusive use of the Boston & Albany Railroad.

The Department of Public Works of Philadelphia, recently advertised for bids for telephones to be used in the police department. The only bid received was from the Bell Company. The bid was $10 for full sets and $5 for single sets.

The Corry Telephone Exchange is the name of a company recently organized at Corry, Pa., to construct an independent telephone exchange.

The bids of the Standard Signal Company and the Gamewell Fire Alarm Telegraph Company for a signal system at Medina, N. Y., have been rejected.

The Clarke Automatic Switch Company of Sioux City, Iowa, has secured a franchise and is at work putting in a telephone system at Rock Rapids, Ia.

The telephone exchange built at Petoskey, Mich., by John W. Chase, of Grand Rapids, and Frank Vincent, of Petoskey, has been opened with 60 subscribers. Bell rates have been cut to $20 and $14.

The Central Union Telephone Company is negotiating for right of way to connect Nashville, Ill., with Mascoutah.

Contract has been let to C. W. Gallagher, of Meridian, Miss., for the construction of a telephone line from Shubuta, Miss., to Cocoa, Ala.

The Automatic Telephone Company has applied for a franchise at Niagara Falls, N. Y.

The New Castle Telephone Company of New Castle, Ind. Capital stock, $4,500. Directors: E. B. Phillips, C. S. Hernly, E. N. Bundy.

The Southern Bell Telephone Company has declared war on the Home Telephone Company of Mobile, Ala., by a reduction of rates to $12 and $20.

New Companies Incorporated.

The Wayne Telephone and Telegraph Company—to connect Auburn, Geneva, Palmyra, Lyons, Clyde, Seneca Falls, Waterloo and numerous smaller places in New York State by telephone. Capital $5,000. Directors: S. E. Bishop, A. B. Bishop, George E. Brisbin, Derick Douglas. John H. Childs and Albert C. Lux, of Clyde, and E. W. Brown, of Palmyra.

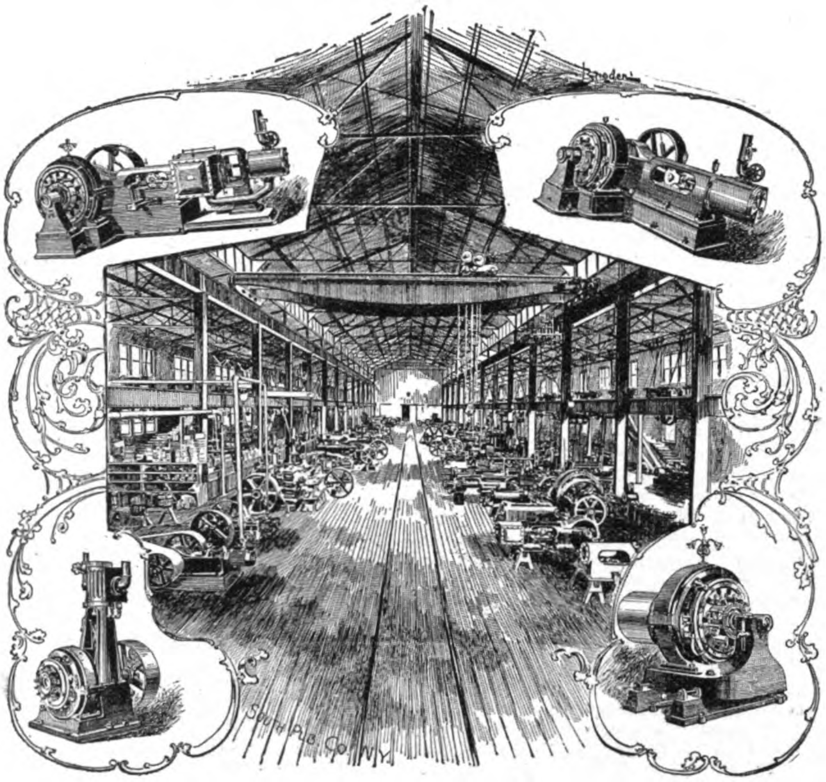
The Blue Earth Valley Telephone and Exchange Company of Winnebago City, Minn., has amended its articles of incorporation increasing the debt limit to $10,000.

The Southern States Telephone Company, with a capital stock of $100,000, has been organized at Baltimore, Md., to construct telephone systems, etc.; Charles E. Fink, president; A. G. Davis, vice-president, and R. B. Hazlett, secretary-treasurer.

The McEwen Engine and Thompson-Ryan Dynamo.

The accompanying illustrations show, somewhat in detail, the workshops and the products of the J. H. McEwen Manufacturing Company.

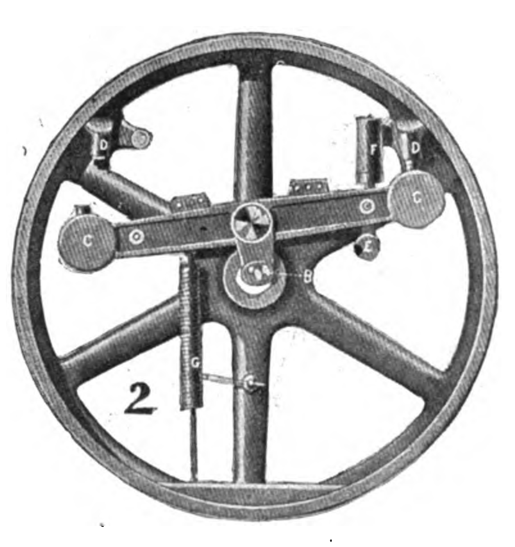
Figure 1 shows an interior view of the machine shop, a steel structure built by the Shiffler Bridge Company, of Pittsburg, Pa. The central part, 60 feet wide, is spanned by a twenty ton electric traveling crane. Within this area all the heavy machines are located. On either side is a wing 30x260 feet the second floors or galleries of which are equipped with light tools. Railroad sidings extend through the center of the main building.



South Pub. Co. N.Y.

Fig. 1.

The McEwen High Speed Engine, one of the products of this company, has been on the market for about four years and has made a very creditable record during that time. Recently a number of improvements have been made in the details of the engine. Fig. 2 is the improved governor, shown by the cut to be extremely simple, having but one bearing and that a roller-pin bearing which requires no lubrication, so that the want of lubrication will not affect its regulation, and as the spring is the only part that is adjustable, there can not be any trouble from misadjustment.



The Thompson-Ryan Dynamo differs in nearly every detail of construction from the ordinary type of generator. The most important feature is a set of series windings surrounding the armature and termed balancing coils. This feature, which is the invention of Prof. Harris J. Ryan of Cornell University, was introduced for the purpose of balancing armature reaction, and carefully conducted scientific tests show that it accomplishes the desired end perfectly. Having no armature reaction to contend with, the designers have been able to introduce into the dynamo many important features never before possible.

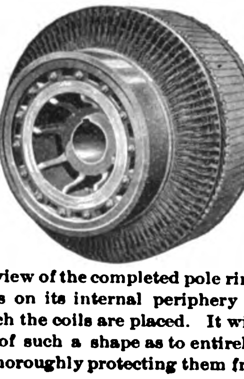
8



9

The field castings of these machines are of steel and consist of but three pieces which are held together by four bolts. One of these castings is the "pole-ring," shown in Fig. 5, through which the balancing coils are wound, and the other two constitute the field ring proper, Fig. 7.

The balancing coils are wound in such a way that the current passes through them across the pole face in the opposite direction from the currents in the armature conductors, and thus the magnetic effects of the armature currents are neutralized.

Fig. 6 is a view of the completed pole ring. The field ring Fig. 7, shows on its internal periphery the "pole necks" around which the coils are placed. It will be seen that the field ring is of such a shape as to entirely enclose the field coils, thus thoroughly protecting them from mechanical injury. On account of the very small amount of field energy required the rise in temperature of the field coils is very slight, notwithstanding the fact that these coils are so nearly surrounded on all sides. No compound winding is used, since the balancing coils afford a compounding vastly more effective than the compound coils of the ordinary dynamo.

All of the armature cores are built of thin plates of a peculiar special steel, the distinctive feature of which is its unusually low hysteresis loss. The plates are stamped out in the form of rings, and a series of long slots are punched near the edges.

The large number of poles used enable the builders to greatly shorten the armature conductors and to use what may be described as the cylindro-hexagonal style of drum winding. In this winding all parts of every conductor of any particular layer lie in the same cylindrical surface, the windings do not bend down over the end of the armature core at any point, and the conductors being placed through the core and below the surface no binding wire is necessary. The commutators are built of tempered copper with pure mica insulation throughout.

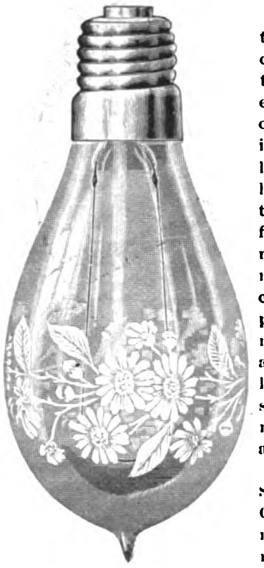
But little heat is developed in the core of the armatures since the quantity of iron is comparatively small and the magnetic density low, and the armature being short and the ends of the windings being thoroughly cooled, it will be readily seen that there is small danger of overheating one of these armatures even with excessive loads.

Fig. 10 is a view of complete brush-holder. The brush-holders are very simple, and hold the brushes in such a way that they require no adjustment, but have only to be slipped into the holder. Working with brush-holders absolutely fixed, there is entire freedom from sparking under any and all conditions of load. The design of the machine peculiarly fits it for running in parallel. Two or more of these machines will work perfectly in parallel, and divide the lightest load evenly or maintain perfect unison with the entire load thrown off.

The Thompson-Ryan Dynamos are built in sizes from 12½ K. W. to 1500 K. W. capacity, both belted and direct connected. Fig. 1 shows the belted dynamo as well as the dynamo direct connected to the different types of the McEwen engine.

The sales office of the company has been established at 26 Cortlandt street, New York City.

Sunbeam Engraved Lamps.



Decorative lamps for interior lighting effects have come to be regarded as essential to the stock equipment of every well-regulated electrical supply store. The rapidly increasing use of this form of lamp has called into being a large variety of designs, so that the most fastidious may find styles suited to their needs, however elaborate they may be. Novel shapes and colorings have long been employed to secure effects with miniature lamps. Satisfactory as the employment of these lamps have been, they are unsuited to certain purposes, notably for richly designed and finished fixtures.

For supplying this want the Sunbeam Incandescent Lamp Company, Chicago, recently made a new departure in furnishing engraved lamps, and they have issued a catalogue showing a number of handsome standard designs as well as samples of special designs that have been made to order. The lamps used in a handsome residence should be in keeping with the shades and fixtures, and it is not improbable that within a few years nothing but ornamental lamps will be used in such lighting.

COMMERCIAL PARAGRAPHS.

Mr. E. E. Cary has assumed the general managership of the Packard Electric Company, Limited, St. Catharines, Ont. This company, with unlimited water power, manufactures the Packard lamps and transformers for Canadian trade.

Among the handsome new calendars for 1896 received by ELECTRICITY are those of Wm. Jessop & Sons, Ltd., 91 John street, New York, makers of the well-known Jessop tool steel; Knowles Steam Pump Works, 93 Liberty street, New York, and Robert Poole & Son Company, founders and machinists, Baltimore, Md.

The Lafayette Engineering and Electric Works, Lafayette, Ind., which recently purchased the patents, plant and appurtenances of the Muncie Electric Works, Muncie, Ind., have become owners of the buildings formerly occupied by the Lafayette Car Works. These buildings have been fitted up with machinery for the manufacture of a complete line of electrical generating apparatus.

A circular which is now finding its way to the desks of central station men thus explains how the high grade of American Incandescent Lamps is maintained: "It has always been our aim to manufacture only high grade lamps, and to this end we use nothing but the best in material and workmanship. The utmost care is exercised in every part of our works. Every material is carefully examined; every chemical is subjected to scientific tests for purity and fitness; every filament is accurately measured and tested; every lamp is tested for vacuum, contact, correct candle-power and voltage, and, before being shipped is subjected to careful scrutiny, and is burned on circuit for a sufficient length of time to develop latent defects.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

(Issued by the Washington Carbon Company.)

INCORPORATIONS.

The Connecticut Engineering Company, Norwich, Conn.—to establish, construct and operate electrical lighting and power plants, etc. Capital stock, $5,000. Promoters: Geo. W. Phillips, A. E. Rich, Geo. W. Hunt, Geo. E. Raymond, Norwich.

La Capital Company, Portland, Maine—to manufacture and deal in electricity for purposes of light, heat and power. Capital stock, $1,500,000. Promoters: Theo. N. Vail, Lyndon, Vt.; Francis A. Houston, Boston, Mass.; Edw. K. Milliken, Deering, Me.

The Martha's Vineyard Electric Light and Power Company, Cottage City, Mass.—to manufacture, generate and sell electricity for light, heat and power. Capital stock, $15,000. Promoters: Jno. A. Duggan, Josiah Quincy, Jno. R. Graham.

The Cherryfield & Milbridge Street Railway Company, Cherryfield, Me.—to build and operate an electric railway from Cherryfield to Milbridge. Capital stock, $30,000. Directors: Samuel D. Leavitt, of Eastport; George A. Curran and George A. Murche, of Calais; William N. Nash and G. R. Campbell, of Cherryfield, and James Mitchell, of Portland.

The Schance & Fair Electric Company, Chrisman, Ill.—to operate telephone, telegraph and electric plants. Capital stock, $6,000. Incorporators: George W. Fair, John G. Schance, Byron Ash and James Hoult.

The Page Ticker Company, New York City. Capital stock, $25,000. Directors: David W. Johns and Willis B. Hale of Cleveland, Ohio; Robert H. Campe, Horace P. Hussey, John E. Wright, Edward T. Hickey and C. M. Artz of New York City.

A bill has been introduced in the House of Representatives at Richmond, Va., to incorporate the Norfolk Electric Light & Power Company, with Paul K. Boyd, B. N. Sperry, George Russell and Walter H. Taylor, all of Norfolk, and J. C. Sperry, of Syracuse, N. Y., as incorporators. The measure authorizes the company to supply natural or artificial lights and electric power for public and private uses, and to transact the general business of an electric company. The capital stock shall not be less than $15,000 and may be increased to $500,000.

The Pittsburg, Braddock & McKeesport Street Railroad Company, Pittsburg, Pa—to build an electric street railway in the City of Pittsburg. Capital stock, $66,000. Promoters: Chas. H. Johnston, Wm. Robison, Pittsburg; Walter Farmariss, Philadelphia, Pa.

The Amarillo Realty and Live Stock Company, Kansas City, Mo.—to do a general real estate business; supply gas, water and electricity, etc. Capital stock, $25,000. Promoters: H. B. Sanborn, Wm. A. Craddock, C. P. Harney, Kansas City.

The stockholders of the electric railroad at Fulton, N. Y., have decided to increase the capital stock of the company from $15,000 to $100,000. A consolidation of the Fulton and Oswego systems is now being arranged.

The Union Traction Company, Reading, Pa. Capital stock, $400,000. Shareholders: Robert N. Carson, I. F. Carson, Nelson Buckley, Philadelphia: Richmond L. Jones, Samuel E. Rigg, Oliver S. Geiger, Frank P. Lauer, James A. O'Reilly, William R. McIlvain, Henry C. England, and George F. Baer, Reading.

The Walker Company of Cleveland, O., has filed articles of incorporation with the Secretary of State at Trenton, N. J. The company is capitalized at $2,000,000, and will manufacture electrical machinery. The incorporators are John Ludwig of Brooklyn and Charles N. King and Martin W. Dixon of Jersey City.

The Sprague Electric Railway Company, Jersey City, N. J.—to manufacture, construct and equip electric and other railways, electric light and power plants and works, etc. Capital stock, $1,000,000. Promoters: Frank J. Sprague, Chas. M. Sprague, Chas. A. Benton, New York City; Edw. C. Platt, Brooklyn, N. Y.; Howard F. Gurney, Jersey City, N. J.

The Standard Building Company, Chicago, Ill.—to contract for and do a general improving, constructing, repairing, building and supply business, including electrical work and public and private improvements of all kinds. Capital stock, $50,000. Promoters: Jos. Fish, Richard Sullivan, H. A. Senf.

The Logan County Electric Light Company, Lincoln, Ill.—to operate electric lights, electric power, and to heat buildings by steam. Capital stock, $10,000. Promoters: John A. Lutz, R. H. Gaines, John St. Gerny, Chas. C. Reed, T. A. Reynolds, Adam Denger, D. H. Harts.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 17, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

551,534. Closed-Conduit Electric-Railway System. Frederick C. Esmond, Brooklyn, N. Y., assignor to the Esmond Electric Traction Company, of West Virginia. Filed April 12, 1895.

551,535. Closed-Conduit, Railway System, Frederick C. Esmond, Brooklyn, N. Y., assignor to the Esmond Electric Traction Company, of West Virginia. Filed April 12, 1895.

551,536. Closed-Conduit Electric-Railway System. Frederick C. Esmond, Brooklyn, N. Y., assignor to the Esmond Electric Traction Company, of West Virginia. Filed April 26, 1895.

551,537. Closed-Conduit System for Electric Railways. Frederick C. Esmond, Brooklyn, N. Y., assignor to the Esmond Electric Traction Company, of West Virginia. Filed Sept. 11, 1895.

551,587. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa., assignor to The Electric Car Company of America, same place. Filed Feb. 23, 1887.

551,664. Electric-Railway-Motor Shield. Isaac F. Baker and William R. McLain, Lynn, Mass., assignors to the Thomson-Houston Electric Company of Connecticut. Filed Nov. 25, 1889.

551,734. Transmission of Electricity to Moving Cars. Thomas Nesom, Indianapolis, Ind., assignor by direct and mesne assignments, of one-half to William D. Eckenrode and Edward S. De Tamble, same place. Filed Sept. 21, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

551,357. Incandescent Electric Lamp. Charles A. Beal, Abington, Mass. Filed Feb. 28, 1895.

551,364. Magnetic Electric-Lamp Holder. Martin H. Collom, Denver, Colo. Filed June 12, 1895.

551,394. Electric Light. David Misell, New York, N. Y. Filed April 5, 1895.

551,451. Electric Lighter. Herbert E. Rider and John Hencken, New York, N. Y., assignors to Robert W. Inman, same place. Filed Nov. 10, 1894.

DYNAMO ELECTRIC MACHINERY, ETC.

551,371. Means for Operating and Regulating Speed of Electric Motors. Rudolf Eickemeyer, Yonkers, N. Y.; Rudolf Eickemeyer, Jr., executor of said Rudolf Eickemeyer, deceased. Filed Dec. 31, 1892.

551,470. Controlling Electric Motors. David Mason, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed April 22, 1892.

551,567. Electric Motor. Merle J. Wightman and Oscar C. G. Urban, Cleveland, Ohio. Filed May 16, 1893. Renewed May 15, 1895.

551,633. Electric Motor. Frank E. Herdman, Winnetka, Ill. Filed Aug. 6, 1894.

551,634. Mechanism for Admission and Regulation of Currents to Motors. Frank E. Herdman, Winnetka, Ill. Filed March 29, 1895.

551,635. Mechanism for Admission of Currents to Motors and Regulation of Current in Same. Frank E. Herdman, Winnetka, Ill. Filed June 28, 1895.

551,712. Dynamo-Electric Machine. Alexander B. Blackburn and William Buchanan, Wolverhampton, England. Filed Oct. 1, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

551,391. Automatic Telephone-Exchange System. William F. Lounsbury, Oswego, N. Y. Filed April 23, 1895.

551,551. Holder for Telephone-Receivers. Fergus W. Martland, Fall River, Mass., assignor of one-half to George W. Hoar, same place. Filed June 10, 1895.

551,674. Telephone-Transmitter. Theodore Grissinger, Mechanicsburg, Pa. Filed Oct. 18, 1894.

MISCELLANEOUS.

551,361. Apparatus for Manufacturing White Lead by Electrolysis. Arthur B. Browne, Cambridge, and Edwin D. Chaplin, Natick, Mass., assignors to the American Lead Company, Kittery, Me. Filed July 2, 1894. Renewed May 18, 1895.

551,372. Electric Program-Clock. Frederick Frick, Waynesborough, Pa. Filed April 29, 1895.

551,388. Strong-Current Protector. Adrian L. Joynes, Paducah, Ky. Filed Jan. 9, 1895.

551,436. Electric Meter. Thomas Duncan, Fort Wayne, Ind. Filed July 11, 1895.

551,565. Process of Renovating Storage Batteries. John Trowbridge, Cambridge, Mass. Filed Oct. 1, 1895.

551,648. Electrolytic Process of Obtaining Precious Metals. Louis Pelatan, Paris, France, and Fabrizio Clerici, Milan, Italy. Filed June 25, 1895.

551,682. Electric Lock. Philip Meyer and Julius A. Meyer, Newark, N. J., assignors of one-third to Emil Blumenhein, same place. Filed Feb. 23, 1895.

551,743. System for Regulating Effective Tension of Electrical Circuits. Hermann O. W. J. Breul, Berlin, Germany. Filed Nov. 17, 1893.

ELECTRICITY.

EDITORIAL NOTES.

The Wizard of War. It is naturally to be expected that the newspaper war which has been raging with the fury of a woman scorned in the editorial offices of New York and London, would prove an incentive to the inventive genius of the world, and under the impetus of a state of belligerency there would be brought forth a variety and kind of life and commerce destroying devices that would astound the world should an opportunity arise to make a demonstration of the possibilities of these besoms of destruction. To conceive and to construct these engines of war, by means of which a handful of men can annihilate an army in the twinkling of an eye, would, it seems, require inventive and mechanical genius of a high order.

Sober-minded people having some knowledge of mechanics, and who have been accustomed to look to the hare-brained, visionary inventor for the most wonderful conceptions, will be not a little surprised to know that Thomas A. Edison is the latest to plot destruction for America's foes. In a page interview, embellished with illustrations, he has told a reporter of the New York *Journal* all about his "aerial torpedoes that will bring swift destruction to the strongest fleets"; he has described his "snake-like chains" that deal death in multiple arc, so to speak. In event of war the Wizard says he will "abandon all else and give my whole energy to the service of my country." He will perfect the sub-marine boat and dynamite gun, and by the magic of his name alone will transform the waters of our coasts into an agency more devastating than bullets. He will surround our great cities with cables that will deal death to all who attempt to cross them, and will charge all the circumambient atmosphere near the enemy's fleet with electricity and consume ships and men alike. Should these devices fail to repel an invading foe, it will still be impossible for a hostile fleet to enter New York harbor.

The present plan of torpedo protection finds little favor with the Wizard of War, and to improve upon it he proposes to erect a number of structures on which a wheel can be placed. "These sunk to the bottom of the sea with a cable around them, would give you an endless cable that could be kept in motion just like the cables that run the street railroads. Torpedoes could be attached to these cables and run out as far from or near the shore as desirable. Its location at any time of its travel could be traced just as readily as if it were stationary. The torpedo could be cut loose, and allowed to shoot toward the surface by some magnetic arrangement and would discharge itself when the pressure of the water on the top was lightened. A few of these cables run out in various directions would make the harbor a mine of death. Nothing afloat could live in it. There is nothing to prevent this being done to-morrow. So you see how quickly defences can be found."

* * *

Acetylene is Profitable. The recent incorporation of a $7,000,000 company at Albany to introduce acetylene gas in New York and neighboring cities calls attention again to the general question of the utility of this gas and to the operations of the promoters who are making fortunes out of the sale of territorial rights.

In the latter part of 1894 the Willson Aluminium Company claimed to have accidentally discovered a very cheap process of making calcium carbide, and a promoting company—the Electro Gas Company—was at once formed for the sale of rights.

A dividend of 60 per cent. on the stock of this company has already been paid, and one of 50 per cent. is promised in the near future. A Chicago sub-company has already paid to the parent company $300,000 as one instalment for the rights in that city. This dividend has been paid, in fact, solely from the sale of rights. Not a single ton of calcium carbide has yet been made in this country, and acetylene gas is not yet a commercial product.

In Electricity for December 26, 1894, there was printed a paper on this subject, by Prof. Francis Wyatt, Ph. D., which attracted wide attention. Among other things, Prof. Wyatt said:

> When Maquenne and Travers were working on these lines, Mr. Thomas L. Willson, of the Willson Aluminium Company, was carrying on experiments in the manufacture of aluminium and calcium alloys at Spray, N. C. In the progress of these experiments, and while attempting to produce metallic calcium in his patent electric furnace, he succeeded in making, from a simple mixture of lime and carbon, and with a current of 4,000 to 5,000 amperes, a fused, black, homogeneous mass, which became solid and brittle when cooled. This substance was shown by analysis to be very pure carbide of calcium, of the formula CaC_2, and the gas which it evolved from the decomposition of water was pure acetylene, formed according to the reaction
>
> $$CaC_2 + 2H_2O = C_2\,H_2 + CCa\,(HO)_2.$$
>
> This contribution to organic chemistry of a plentiful and cheap source of acetylene, by so easy and simple a method of making calcium carbide, must be regarded as one of the most important of the valuable resources added to the chemical industry by electrical engineers, and the Willson Aluminium Company has shown its appreciation of it by continuing to manufacture the carbide on the small scale. A new corporation has also been formed, which is known as the Electro Gas Company, and which proposes to erect a large new plant for its wholesale production. . . . As the actual result of its recent practice, the Willson Aluminium Company has found that it can produce one short ton of calcium carbide from a mixture of 1,200 lbs. of fine coal dust and 2,000 lbs. of burnt lime, and at an expenditure of about 180 electrical H. P. per hour for 12 hours. These figures are not very far from those required by theory, and

> they agree very closely with those given by H. Moissan, who has also produced the carbide in an electrical furnace of his own invention. It would, therefore, seem safe to formulate the approximate cost of production somewhat as follows for both the carbide and the acetylene:
>
> | | |
> |---|---|
> | 1,200 lbs. coal dust, say | $2.50 |
> | 2,000 lbs. powered burnt lime | 4.00 |
> | 180 E. H. P. from water at, say, 50c. per hour for 12 hours | 6.00 |
> | Labor, etc. | 2.50 |
> | Cost per 2,000 lbs. CaC_2 say | $15.00 |
> | Cost per 2,000 lbs. C_2H_2, say | $87.00 |
>
> These figures would hold good, not only for the present works in North Carolina, but at any other place where cheap water power and equally cheap coal, lime and labor are procurable and accessible. . . . The experiments that have been made by the Electro Gas Company have satisfactorily demonstrated that one short ton of calcium carbide will produce, by merely mixing it with water, about 10,500 cubic feet of acetylene, which, when mixed with the required amount of air produces a gas equal in illuminating value to 100,000 cubic feet of city gas of 22 to 25 candle power per 5 feet standard burner. If to the estimated cost already given for the calcium carbide there be added, say $15 per ton for freight, incidentals and profit, the material for producing such a gas could be obtained at nearly all points for 30 cents per 1,000 cubic feet ready for burning, and the convenience with which the calcium carbide can be packed and freighted, combined with the easy preparation of the gas itself in great or small quantities, at any time, should enable it, if not to be adopted for the common supply of large cities, to supply the requirements of country hotels and dwelling houses and of railway cars.

Prof. Wyatt's paper was really the prospectus upon which the Electro Gas Company went into business, and that the business has been profitable up to date is proved by the payment of a 60 per cent. dividend.

Now that a full year has passed, it is proper to inquire how far the promises have been realized.

Is acetylene gas being used commercially? No. Has the Electro Gas Company built a plant for the manufacture of calcium carbide? No. Is any one making calcium carbide in quantities? No. What have investors bought?

The *Engineering and Mining Journal* prints a communication which gives considerable information on this point:

> Acetylene gas is a combination of hydrogen and carbon and is the product of the decomposition of calcic carbide and water. Calcic carbide is the combination of calcium and carbon and is a product resulting from the action of the heat of the electric arc on lime and coke. A short ton of calcic carbide, 95 per cent pure, may be counted upon to produce 10,000 cu. ft. of illuminating gas, which gas is over ten times brighter than the present average illuminating gas. If calcic carbide could be produced for $30 per ton, including conversion of the same into gas, the resulting gas would cost $3 per thousand: hence, as this gas is ten times brighter than ordinary illuminating gas, the proportionate amount of illumination could be had for 30c. per thousand. The production of water gas in the United States is now costing from 30c. to 40c., or more, per thousand, varying according to the care in the management of the work. This figure does not take into consideration the handling of the gas further than putting it in the holder. Calcic carbide is now being produced and has been for about two years past. at Neuhausen-on-the-Rhine, with water power, and in one of the most complete electrical and industrial plants in the world, at a cost of 3½c. per lb. or $70 a short ton.
>
> It is explained by the promoters of the scheme to those who are able to get near the point of the business, that "Here we have an electric furnace, in the bottom of which is a cathode, in the top of which we have an anode (the first a carbon plate, the second one or more large sticks of carbon); here is our dynamo, here is our water-wheel, here is our old millrace, and where is the cost of power? Here is a one-armed man feeding ground lime and coke into the furnace, and here is a negro-boy working the anode up and down so as to maintain the arc. There is the pay roll; here is the bill for the lime and coke. Where is this great expense account we hear about?"
>
> This situation apparently presents very simple ground for investigation. As a matter of fact it is a little too complex for the ordinary technical investigator, and is far beyond the public. It combines several important elements which require investigation by men who are fitted to investigate in three important fields: (1) Mechanical engineering, (2) Chemistry and (3) Electricity. It has not been passed upon, publicly, by men of the character mentioned. It is safe to assume that the promoters in question have not discovered any new principle in electricity. Unless they have done so, it is equally safe to assume that with their primitive methods they cannot produce calcic carbide as cheaply as it is being made at Neuhausen with the most perfect facilities which capital can employ. It is held by a few students of this subject that the same ignorance which prevented the promoters of this operation, knowing that they had made calcic carbide originally, is responsible, together with the enthusiasm of the moment, for their further failure to discover the leak in their estimates. It is possible that that leak may be found in the fact that they fail to charge themselves with sufficient expense for power. It is said that the Electro Gas Company has arranged to put up calcic carbide works on the line of the Niagara Falls Power Company and has contracted with that company for power at the rate of $25 per horse power per annum. It will be found that paying for their power at this rate, if they run every hour and every week day of the year, and use every atom of their electric current in the production of calcic carbide, that their power will cost them about $11 per ton of carbide produced. At Neuhausen, only about 20 per cent. of the total efficiency of the heat of the arc is utilized in forming the calcic carbide. $11 × 5 = $55. The Pittsburg Reduction Company has had a wide experience with electric power and heat. No one to date, it seems, has succeeded in patenting calcic carbide. Patents have been secured on several ways of utilizing the same. The Pittsburg Reduction Company, apparently being aware of these facts, made a line of experiments which are said to have been much more exhaustive than any work yet done, or possible, by the Willson Alluminium Company, and stopped the work because of the fact that the production of the calcic carbide cost them, instead of $70 per short ton, as at Neuhausen, at the rate of about $150 per ton. At this price they saw little use chemically for the product; and, as their acetylene gas product would cost them $15 per thousand, or $1.50 per thousand for illumination proportioned to ordinary gas, they left the field
>
> It is supposed that the reason for the failure to secure the total effectiveness of the heat of the arc in the production of carbide is found in the impossibility to feed the ground lime and coke into the furnace so that the arc may be continuously maintained. When the crushed lime and coke are placed on the cathode, and when the top of the pile reaches a proper distance from the anode or the carbon sticks, quite the full effect of the arc is had, and calcic carbide is formed. Should the top of the pile be too far beneath the anode, as long as this continues the power is being wasted, the anode being burned away. Should the top of the pile of coke and lime be too high and touch the anode, the current is short-circuited, and the waste goes on as long as this state remains unchanged. Various methods are being tried for correcting this state of affairs, which will be best understood by pointing to the clockwork now used for a similar reason in the arc lights in daily use, which are all imperfect in the respect in question to date. Industries depending upon electric arc are proceeding without much hope of correcting this serious drawback. Their hope of economy lies in cheap generating power. With very cheap power, say $2 per horse power per year, or the discovery of means for the utilization of the full theoretical power of the heat of the electric arc, the problem of the production of calcic carbide at $30 per ton and acetylene gas at $3 per thousand will be solved. So far as the Willson Company, or any other carbide producer, is concerned, these accomplishments are as far away as the discovery of a method to get in general use more than 20 per cent. of the full energy of coal.

The incorporators of the New York Carbide and Acetylene Company are Elias C. Benedict, Anthony N. Brady, Walton Ferguson, Frederic P. Olcott, John Sloane, and Samuel Thorne. They are likely to pay a high price for their education as to the commercial possibilities of acetylene gas.

The patents of the Willson Company are worthless. The manufacture of calcium carbide is free to the world. The only reason why it is not now being manufactured in dozens of places is that it costs more than it is worth. The Willson people first claimed to have reduced the cost of manufacture to $5 @ $7 per ton. This estimate has been growing until now $40 is the cost claimed. Even at this price there would be little incentive to introduce acetylene as a competitor of water gas, for the reason that, although it were cheaper there are many obstacles in the way of introducing acetylene even as an enricher of ordinary gas. The first is that it burns ordinarily with a very smoky flame. Means must be devised to overcome this before it can be used successfully as an illuminant. In the second place, the gas unites directly with copper, forming a highly explosive compound, and therefore copper or brass must be eliminated from the fixtures in which it is to be used. The latter objection is a serious one, and impossible to overcome except by selling the gas so cheap that consumers can afford to put in new fixtures.

The spectacle of conservative capitalists investing their money in such rights as the Electro Gas Company and the Standard Telephone Company offer is a curious one, and provides a subject for the careful study of psychologists. What are these men thinking of? As far as the original promoters are concerned, it is easy to see what they are thinking of. Stock in the parent Electro Gas Company, par value $100, has been sold as high as $1,000 a share.

Electricity as an illuminant has nothing to fear from the competition of acetylene gas at present. But we recommend Mr. Thomas L. Willson, Mr. George F. Seward and the rest to go slow unless they value money dishonestly made more than their reputation as business men.

Questions Soon Answered.

Commenting last week upon the serious problems which confront railway companies in the large cities, where the demand for rapid transit is increasing and where hostility to the overhead trolley grows more formidable every year, the conclusion was reached that in many localities neither the cable nor an open-conduit system could be looked to for relief, and we asked the question "What is there left?" We were unaware at the time that there would so soon be an answer to our question by a thorough and practical demonstration in this city.

In the same issue appeared some comments of the *American Engineer and Railroad Journal* on the "Bugbears of Electric Traction." These were, according to our esteemed contemporary, the acknowledged difficulty of getting two motors to work in unison on one car, the necessary difficulties of the gearing problem, pounding of the rails and consequent flattening of the wheels.

The demonstration above referred to will also have an important bearing on the question of whether these "bugbears" can be eliminated in electric railway practice and is worthy of careful consideration.

The Johnson-Lundell Company have arranged with the Metropolitan Traction Company to put in a working system in Thirty-fourth street from Tenth avenue to the North River to prove during the coming winter the utility of this closed conduit in connection with a single-motor car equipment.

This system was thoroughly described in ELECTRICITY for March 16, 1894, since which time, however, several important improvements have been made, notably in insuring protection against the rail remaining charged after the car had passed any contact switch.

The street chosen is admirably adapted for a conclusive test, and its choice shows the confidence of the promoters. It has a steep grade, takes in some of the most poorly drained territory in the city, and for heavy traffic is one of the busiest of our streets. Every obstacle which would be encountered in the entire Belt Line system will be met with here. The cars will be in operation by January 10 or 15, and every opportunity will be afforded to railway men and the public generally for complete and exhaustive tests. If the General Electric Company adopt the same policy with regard to the open conduit system in Lenox avenue, a good many disputed points as between the closed and open conduit systems will be settled forever.

Every detail of the equipment is designed to represent the highest development of economical practice, the generator being driven by a Westinghouse gas engine.

The single motor idea is not a new one, but has not before proved successful. One of the obstacles *in* previous experiments has been in the control of the motor. This has been obviated entirely by Mr. Lundell by giving the armature two sets of windings. By handling the sets of coils separately the motor is susceptible of series multiple control. The method of suspension on the frame of the truck dispels at once all the "bugbears" referred to by our steam railway critic.

Under the Searchlight.

Views and Opinions on Timely Topics.

New Unit for Hous-Kennooley.

(From the Sioux Falls Argus-Leader.)

J. E. Tomlinson received on Monday a new four ton dynamo for his electric light plant.

Tadpoles as Pole Finders.

A French physician has found that if an electric current be passed through water in which a tadpole is swimming the animal will immediately turn so that its head is toward the anode, or, in other words, so that the current passes into its mouth and out from its tail; its head will therefore always point towards the positive pole. The effect on a lot of tadpoles in the same vessel is quite amusing.

THE doctors of Buffalo, N. Y., don't want the peace and quiet of Franklin street in that city disturbed by the clang of Tom Johnson's trolley gong. At a meeting held a few days ago to protest against the granting of a franchise to the Buffalo Traction Company, Dr. Delancy Rochester, acting as spokesman for the allopathic, homœopathic and eclectic kickers, gave utterance to the following:

"The noise of a trolley car passing would injure a physician's business. It would be impossible for us to hear a heart-beat with the trolley's clanging, banging and zipping all the time. It would be impossible for us to properly diagnose a disease."

The Latest Niagara Wheel.

Of the making of water wheels to utilize the Falls of Niagara the same may be said as was said of the making of books. The latest device of this kind is the invention of L. W. Hotchkiss, described by the Niagara Falls *Cataract* as "the well-known quarryman at Lewiston, who was brought up along the banks of the Gorge, and who has carefully studied the currents and other conditions." This gentleman has "a current motor scheme in mind before which all other current motors sink into insignificance."

Inventor Hotchkiss contemplates the building of a steel arch across the Gorge below the falls, which "is to be used to sustain an undershot wheel extending from shore to shore, the power to be equally divided between the two countries, and transmitted where it is wanted. The paddles of the motor are all to be attached to the main shaft and immersed to such a depth as to furnish the most power. The main shaft would extend across the river, with a power-house at each end. The location selected for the bridge and motor is at the outlet of the whirlpool where the river is narrowest, and the bridge is to be used for traffic. It is estimated that such a wheel would develop 50,000 horse power, and ice and other debris floating down against the paddles would only add to the power exerted."

SERVICE in a corporation which has no body to be kicked, no soul to be damned, appears to have a deadening effect on the finer sensibilities of most men so employed. A recent incident at the new Manhattan Athletic Club illustrates this. Mr. A. G. Mills, vice-president of the Otis Elevator Company, happened to be a member of a committee for the purchase of some new elevators. He graciously informed his associates that he knew all about electric elevators, while they knew nothing. Therefore the matter should be left to him. He would see to it that his firm put them in at cost. To satisfy themselves on this point, the committee were urged to call on Stokes & Parrish, the Whittier Machine Company and the Otis Company for bids.

How many members of the committee knew that the relations between these concerns, all in the Elevator Trust, are such that the bids of all three of them can be made up in the office of the Otis Elevator Company whenever it seems best to do so?

* * *

THE anti-English sentiment in Caracas, Veneuzela, is very bitter. A movement is now on foot to displace all English telephones with those of American manufacture.

Johnson--Sprague--Weston.

A few weeks ago ELECTRICITY printed a notice of the incorporation of the Johnson Lundell Railway Company coupled with the news that Mr. Edward H. Johnson would soon again be an active factor in electric railway work.

Last week it was recorded that Mr. Frank J. Sprague is in the field with the Sprague Electric Railway Company, with assurances of startling developments in the line of equipment for elevated and suburban roads.

This week the Weston General Company is announced, with Messrs. Edward Weston, F. C. Matthiessen and Henry E. Niese as incorporators, to develop electrical inventions and devices and manufacture and sell electrical machinery and appliances connected therewith.

Which all looks as though the pioneer inventors and hustlers think there is money yet to be made in the electrical business, and many improvements yet to be introduced before the development reaches the ultimate.

OBITUARY.

Mr. Merritt Clarke, who died on Christmas Eve at his home in Derby, Conn., was buried on the 27th. Mr. Clarke was eighty years old on Dec. 4 last and had spent the greater part of his life in the community where he died. He leaves six children, the youngest of whom is Mr. W. J. Clarke of the General Electric Company.

Brooklyn Institute.

Prof. M. I. Pupin, of Columbia College, will deliver an illustrated lecture before the Brooklyn Institute of Arts and Sciences on the evening of the 3d inst. on "Electrical Resonance and Alternating Current."

The Hunnings Transmitter.

(*From the original MS., now in possession of* ELECTRICITY.)

IN RE TELEPHONE—Statement by the Reverend Henry Hunnings, M. A. Oxon., of Portland House, Ryde, Isle of Wight.

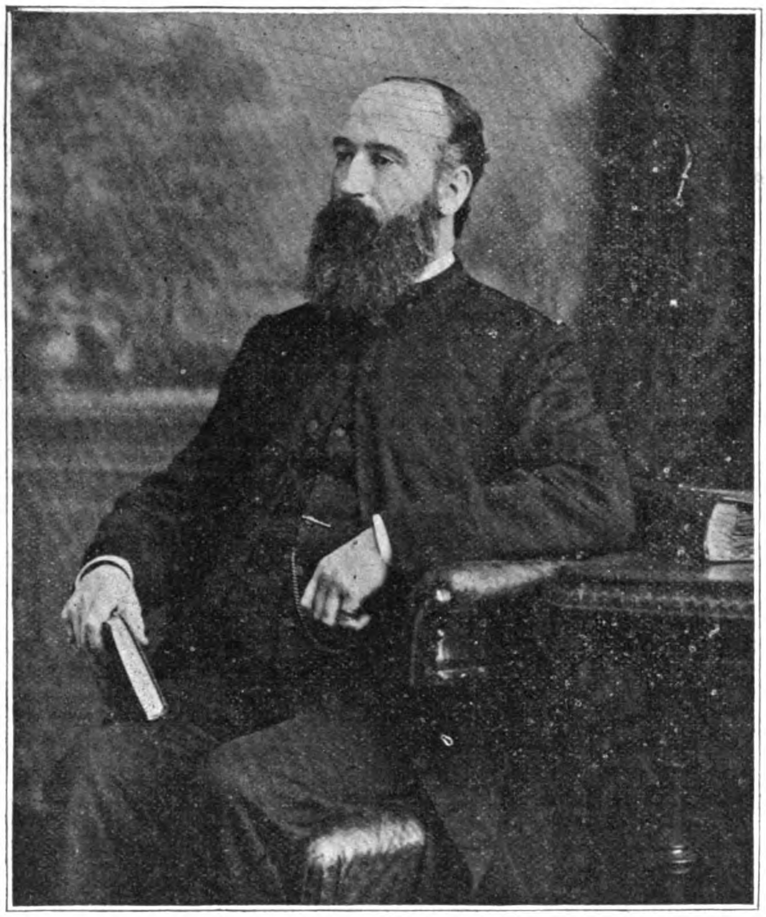
Having from childhood been brought up in an "electrical atmosphere," it was only natural that when Bell's telephone was introduced into England I should immediately turn my attention to it; and more especially as it actually carried out a proposition which my eldest brother made to me some years before. His idea was that a vibrating diaphragm might be arranged to control a voltaic current at one end of a line wire and that those vibrations should be reproduced at the other end by means of an electromagnet acting upon a similar vibrating diaphragm, so that he might be asked a question and give an answer without the trouble of leaving his office. I did not see at that time how it was possible to accomplish such a thing and in fact spoke as no scientific man should speak, and said it was *impossible*. It may well be imagined that when Bell's telephone was brought before the notice of the British Association, in 1877, I should of course take the matter into consideration, the Bell telephone carrying into practical effect my brother's desire of some years before. On experimenting with it, I was greatly disappointed with the results, viz., the *feebleness* with which the voice was reproduced, and I came to the conclusion that what was wanted was a transmitter which would control a direct voltaic current, and to that I turned my attention.

In November, 1877, I made a transmitter with a vibrating diaphragm of paper, and also one with a smaller iron diaphragm. I tried from one to many points, but the adjustment was so delicate and so easily disarranged that I reluctantly gave up my theory of *fixed points*. I need not detail the various experiments I made, and over which I lost a great deal of time, but go on at once to say that I was ignorant of what was being done or had been done in America. I was working entirely upon my own lines and upon my own theories.

My next step was to arrange a row of cinders (about 18 inches long) upon a tightly stretched piece of paper. This gave articulate speech, but very feebly. At last about April, 1878, I thought I would try the following experiment: I turned a wooden ring about two inches in diameter and about $\frac{3}{8}$ deep, a paper diaphragm covered with tinfoil was affixed to either side and the intervening space filled in with crushed cinders. This gave very fair and encouraging results, and in the end I took out "letters patent" in the following September. This step I should have taken earlier had it not been for the great discouragement I received from the Post Office authorities. In my simplicity I thought the Government of the country was the fountain-head to go to with such an invention. I accordingly sought an interview with the Postal authorities in the summer of 1878, and was introduced by a nephew of the late Sir Rowland Hill. Mr. Preece was unfortunately away, and the gentleman I saw poured so much cold water upon me and telephones in general that I returned to the country much disheartened. After the genial warmth of the summer months, spent in a pleasant part of Yorkshire, I sufficiently recovered animation to venture upon a "Provisional Protection" so that I might allow the instrument to be experimented upon. This "protection" was granted on the 16th September, but the instrument had undergone no vital change since the previous June, and in fact was the first transmitter invented, or as far as I can learn, the only one in existence in England at that date.

And now may come some remarks with regard to my claim and Mr. Edison's. It has been alleged that my patent is an infringement of Mr. Edison's, but if we compare the action of the two transmitters it will, I think, be clear to every unbiassed person that they act upon two different principles. In January, 1883, I wrote to Mr. Preece upon the subject and he replied upon the 26th: "I am perfectly satisfied that the contact theory is the right one and the pressure theory is—in plain Saxon 'all rot.' I do not think you have anything to fear from Edison's patent."

Points of contact had been my aim from the very first, and why I say in my specification "preferably oven-made engine coke" is because of its specific gravity compared with its bulk. I have obtained much louder results from fine brass turnings; but success with these is so very variable, owing to the heavy specific gravity compared bulk for bulk with oven-made engine coke, that for practical purposes brass or any other metal turnings are unsuitable and altogether unmanageable. At the same time I reserve to myself the right to use any conducting substance in a granular form and in a loose state. Th innumerable *points of contact* and the mobility of the same are my claims to originality.



I believe the above to be a correct and concise history of my invention.

H. Hunnings, M. A. Oxon.

Ryde, I. of W.
Jan. 3rd 1882.

Now let us turn to Mr. Edison's own account of his transmitter experiments and we find him stating that "a small disk made of lampblack taken from a smoking petroleum lamp gave splendid results. It was soon found upon investigation that the resistance of the disk could be varied from 300 ohms to the fractional part of a single ohm by *pressure* alone." We can now compare the two instruments. Mr. Edison's transmitter is the "pressure" system—mine, points of contact and the mobility of the same.

Towards the end of December, 1878, my instruments were publicly used on Messrs. Bright's wire between Manchester and Rochdale. On the 3d of January, 1879, the Earl of Derby inspected them "and was astonished to find that the transmissions were so distinct." In a private letter to me his Lordship said he never heard the telephone so loud and perfectly before.

At the British Association meeting at Sheffield my transmitters were exhibited and came under the notice of Mr. Edison's agent.

On the 22d and 23d January, 1880, I had the pleasure of making several tests in company with Mr. Preece. On the latter day, Mr. Edison's agent, Mr. Adams, was present and was very much astonished to find that my transmitter was so much superior to, and could get through so much more "induction" than Edison's.

On the 2d February, 1880, the Bell Telephone Company entered into negotiations with me for the purchase of my patent, but on the amalgamation of the two companies the negotiations came to an end.

I believe the above to be a correct and concise history of my invention.

H. Hunnings, M. A. Oxon.

Ryde, I. of W., January 3d, 1882.

Chicago Electrical Association.

"What Next in Electrical Railway Work?" was the theme of discussion at the meeting of the Chicago Electrical Association held Dec. 20. The paper of the evening was by Mr. J. R. Cravath of the *Street Railway Review*. He discussed at considerable length the underground conduit and other systems, and said that while the conduit system might be operated successfully in clean, well-drained residence streets, to attempt to employ it under the conditions which obtained in the down-town streets of Chicago would be to invite probable failure.

COMPARATIVE TESTS OF STEAM BOILERS WITH DIFFERENT KINDS OF COAL.*

BY DR. CHARLES E. EMERY.

Experimentally, hydrogen burned in oxygen has over four times the calorific value of carbon. It seems evident, therefore, that the value of the fuel should be greater the larger the proportion of hydrogen it contains, but such is not the case. The evidence to the contrary was at an early date overwhelming, and it was claimed by many that the commercial value of coal of all kinds was practically proportioned to the carbon element alone. From the weight of evidence, it appears to the writer that this simple rule is, in a general sense, as nearly accurate as any other that has been suggested for a number of varieties of coal burned with ordinary apparatus and management.

It has also been suggested that the practical evaporation bears a definite relation to the proportion of "fixed combustible," or that remaining after the volatile matter in the coal has been distilled off; but from the weight of evidence it appears to the writer that this proposed rule is not generally applicable, though it should be borne in mind that the proportions of fixed and volatile combustible matter are used universally as a means of identifying and classifying different kinds of fuel. A well-established result of this classification is that the evaporative efficiencies of anthracite and semi-bituminous coals containing less than 20 per cent. of volatile combustible are, in a general sense, nearly equal, independent of chemical composition; though, as a rule, the theoretical calorific value increases considerably, and the practical evaporation slightly, with the increase of volatile matter within these limits. On the contrary, as the proportion of volatile matter increases above such limits, the percentage of the total calorific value of the fuel utilized is, as a rule, reduced materially, with ordinary apparatus and management. It is true that the calorific value of many coals reduces as the percentage of volatile matter is increased; but this is not always the case, particularly with the coals of this country. The percentage of efficiency is, however, in general decreased with the increase of volatile matter above the limits mentioned.

Most of the coals used on the seaboard and in the eastern part of the United States have less than 20 per cent. volatile matter in their composition, and, in a general sense, with conditions favorable to each, give substantially like evaporative results. Each, however, has peculiarities of its own, so that, with ordinary apparatus and management, the results vary somewhat, and the mechanical structure of the coal seems to have more influence on the result than the chemical composition. The practical results for the softer coals of the same class, substantially alike in appearance and composition, also vary in much the same way; but in general all show a falling off in evaporative efficiency when the volatile matter is greater than 20 per cent.

The above will serve to give a general impression of the information available on the subject. The explanations that have been made of various observed phenomena are more or less conflicting because based on experiments limited in number, or carried out in a manner which did not develop all the conditions. One difficult question to explain has been the variations in practical result shown by coals of substantially the same chemical composition. These differences have frequently been referred to a less percentage of refuse, and to differences in the refuse as respects the formation of clinkers, etc., whereby less labor was required to handle the fires, the fire-doors were opened less, and there was less heat carried away in the refuse itself. All these practical questions are of importance; but it is probable that the more important variations in result are due to the different way in which the components are united chemically, and, as stated, to a difference in mechanical structure of the coal. It is known that a difference even in the allotroptic form of the element affects the calorific value, Berthelot finding nearly 5 per cent. difference in calorific value due to the combustion of carbon in the form of a diamond, and of amorphous wood charcoal. It is known that comparing coals of very similar composition, some will smut the hands and others will not; some have little cohesion, like rotten wood, others are like stone. The suggestion that the calorific value may vary with the mechanical structure is, therefore, very probable. It has occurred to the writer that these differences may be very much akin to those resulting from the mixtures and combinations of carbon and iron, resulting in cast iron, malleable iron, soft and hardened steel, etc.

---

* Abstract of paper read at the New York meeting of the American Society of Mechanical Engineers, December, 1895.

In burning coal with a large proportion of volatile matter, there results a combined combustion and wasteful distillation of the volatile products, which latter are not consumed in ordinary furnaces but escape to the chimney. The experiments show, as stated, that the loss of heat increases with the proportion of volatile products, and Rankine gives the carbon value of losses on the several assumptions: first, that hydrogen only is wasted; second, that the carbon is combined with hydrogen in the same proportion as in "marsh gas" and the product wasted; and third, that the combination is in the same proportion as in "olefiant gas" and the product wasted. This would seem to imply that, at the temperature of the furnace, carbon and hydrogen unite to form hydro-carbons, but this is probably not the case. Any hydro-carbons that appear are doubtless condensed and combined as a part of the coal itself, released as gases by the heat of the furnace, and in the main carried away, wasting the heat due to their chemical composition, which it is interesting to note is less than the sum of the calorific values of the elements. The imperfect combustion resulting from driving off the volatile matter can, in part at least, be explained by the great volumes of gases disengaged, which prevent a proper admixture with the air supplied, and which, moreover, absorb a portion of the heat of the combustible consumed.

[The tests made by Prof. Walter R. Johnson, of Philadelphia, in 1841, under authority of Congress, the tests made under the directions of Chief Engineer B. F. Isherwood, U. S. N., 1858–1862, and the discussion of the reports of these tests by various authorities, both American and foreign, are here reviewed at some length by Dr. Emery.]

The general conclusion to be derived from the study of the numerous experiments with coals varying considerably in the percentage of volatile matter seems to be that, while the average results of evaporative tests with a number of coals from a given region may indicate an approximate general law, the individual experiments vary so much among themselves, or even from the average, that they cannot be accurately compared with each other either directly or by any fixed law of progression, and this will be particularly the case when a highly bituminous coal is used in one case and an anthracite or semi-bituminous in the other. These limitations are particularly emphasized by the fact that the results of the tests presented can only be compared with those made with customary apparatus and customary management. Mr. Kent points out that much better results have been obtained in practice with Western coals than those given by Johnson, though he found that the foreign and American tests corresponded well with each other. In order to test the relative efficiencies of different boilers in different locations, using different coals under different conditions, it would be necessary to ascertain the value of the improved furnace and of the improved care exercised in making a particular test, in addition to such information as was available about the theoretical and practical calorific value of the coals employed. Even then no accurate comparison could be made unless the practical evaporative efficiency under standard conditions of the coal used had been previously determined; and in determining the relative value of the coals still another difficulty is encountered, to wit, the variations in the efficiencies of the boilers themselves. The efficiency of the boiler is usually the very question to be settled in a boiler test; but to ascertain the comparative calorific value of different fuels, in order to use them in standard tests, allowance must be made for the difference in efficiency if different boilers are used or if the rate of combustion is varied.

The writer, in the preparation of the General Report of Group XX., Centennial Exhibition, presented curves and tables based on experiments made in the United States Navy which very satisfactorily show the variations in the evaporative efficiency of a boiler due to different rates of combustion; and the results there stated may be applied with confidence to tests of boilers that have been designed for economy by insuring a thorough distribution of the products of combustion over all the heating surfaces. Such a boiler cannot be forced much above its capacity without the use of artificial draught and is therefore only adapted for positions where the load is comparatively steady. When the demands vary at short intervals it is necessary that the boiler be constructed so that it will burn coal freely when required. With such construction it is possible to obtain considerable difference in capacity, and this fact makes such a boiler of no better or even lower efficiency at comparatively small powers, thus reversing the rule compared with boilers proportioned for economy.

The falling off in evaporative efficiency of bituminous coals, and indeed the low results with other coals, has been attributed by various writers, on the one hand, to a deficiency in the air supply, and, in connection with experiments with chimney gases, to a surplus of air admitted. Professor Unwin states as his opinion that the "chief loss of efficiency in the operation of the boilers is the heat carried into the chimney," and "this depends on simple conditions of air supply." Rankine makes a somewhat similar statement, but, from information now available, it appears safe to say that such conclusion is not warranted, though, doubtless, improvements in the result can be obtained in that way. If such a simple proposition were true, we would sometimes obtain very high evaporative results from ordinary boilers with rich bituminous coals; but the best efforts seem only to bring such results up, or nearly up, to those obtained with anthracite. Mr. Kent hints that hot gas and air, or the conditions obtaining with a regenerative furnace, are necessary.

With the expectation that mere regulation of the air supply would secure great economy of fuel, there has been invented abroad an instrument called the "dasymeter" to indicate the percentage of carbonic acid in the products of combustion compared with pure air. The indication depends on the weight of a vessel through which gases are being continually drawn from the chimney of a steam boiler. It is stated that with practice the stoker "learns what alterations of the damper or fire-door or thickness of fuel on the grate are necessary, or whether a permanent alteration of grate area is desirable." Comparative experiments of ten hours' duration were made with a boiler having sixteen square feet of grate surface and 1,076 square feet of heating surface, with the following results:

Coal per 1,000 pounds of steam.	Percentage CO_2 by dasymeter.	Chimney loss.
152.6	6.8	33
125	13.1	13

At first blush these results seem to show the great value of the dasymeter, and indeed a distinguished gentleman abroad has allowed himself to speak in enthusiastic terms of a device which will enable the percentage of carbonic acid to be continually read off "as readily as the steam pressure on a gauge," but it is the office of the engineer to look at the facts presented in a critical way. It seems suspicious to have the evaporation stated in terms of coal per 1,000 pounds of water, and by taking the reciprocal, so that the results appear in the customary way, we find that the boiler only evaporated 6.55 pounds of water per pound of coal without the dasymeter, and 8 pounds with it. The first result is altogether too low for any conditions, those actually obtaining not being mentioned, whereas the second result is about what should be expected under ordinary conditions; thus raising the suspicion that the trials were made in the interests of the inventor of the particular dasymeter, but once published reached the eye of one always on the lookout for improvements, who kindly attributed to others the same honesty of purpose as himself without thinking of conditions which unavoidably enter into commercial transactions.

From what has been said, however, in the preceding pages it will be seen that the greatest losses occur from the fact that only the carbon in the coal is fairly well consumed, and the hydrogen, though of a higher calorific value, has little or no influence on the result. It is believed that this is a condition of things which needs further investigation with the view of improvement.

It is a maxim in making tests of all kinds to arrange all the conditions alike except the particular one to be examined. In applying this principle to the matter in hand it becomes evident, in view of the varying results obtained with coals of similar composition, that if the comparative evaporative efficiencies of different boilers are to be tested with superlative accuracy it should be with the same variety of coal burned in furnaces of like construction under standard conditions. The value of improvements in furnaces should not only be tried with the same coal, but with the same or exactly similar boilers. Tests of the efficiency of different coals offer more difficulty, as furnaces of a particular form and boilers of particular proportions are not strictly adapted for obtaining the best results from all varieties. It would seem, therefore, necessary in comparing different coals to make changes of detail suited to each, but the same rate of evaporation per square foot of heating surface should be maintained. If other than ordinary details or boilers of unusual proportions are used, the experiments made with the same would not be strictly comparable with tests made of the same coal with different details or in boilers of different proportions, and this of itself is sufficient to prevent in general any accurate comparison of boiler tests made with different kinds of coal in different parts of the country.

The difficulties in comparing the results of tests with steam boilers are very much reduced if such tests are made with the better grades of anthracite or semi-bituminous coals ordinarily sold in the market, as the difference in results between the same is, as shown by the elaborate Isherwood experiments, very small. As clearly pointed out, the practical evaporations are not accurately proportioned to the calorific values shown by calorimeter or chemical composition, but they can be compared with a fair degree of accuracy by stating the results in units of evaporation per pound of combustible. It does not appear, everything considered, that for tests of different boilers with different coals of the same general character any other plan will give results any more accurate. There will be some variations in particular samples of the different coals, even of the better grades, which will affect the results for comparison with other boilers tested with different samples; but these minor differences can only be eliminated by the adoption of the suggestion that in all standard tests of boilers, where great accuracy is required, a particular kind of fuel be employed, which, from the experience of engineers in general, is quite uniform in quality, as regularly delivered in the market. A modification of this would be to compare the boilers in a given location by their relative performances with a fair sample of a particular fuel available in that particular locality, when a careful comparison of the standard fuel adopted in one section with that employed in another would enable the performances of all boilers in different sections to be compared.

DUST DESTRUCTORS AS STEAM PRODUCERS FOR ELECTRICITY SUPPLY STATIONS.*

BY E. MANVILLE.

I do not propose to describe all the various methods and systems on which dust destructors have been constructed, and I will therefore confine myself to a description of those two installations at present being erected for the Vestry of Shoreditch and the Corporation of Swansea.

In the year 1892 the Vestry of St. Leonard, Shoreditch, in London, had in view the erection of a central electric supply station and at the same time of a dust destructor. I being appointed to advise the authorities in relation to electric lighting, strongly recommended them to combine the two schemes. A great deal of careful investigation was carried out on their behalf to ascertain what power might reasonably be expected as obtainable from the burning of their ashbin refuse, and as a result of this investigation I felt enabled to assure them that all the steam required for the estimated electrical output likely in the first instance to be demanded from their electric light station might be obtained from a properly designed dust destructor, without the use of other fuel.

When the unsorted refuse was burnt directly in a boiler, it evaporated as much as 3 lb. of water from and at 212° Fahrenheit, and my opinion that the steam required could be obtained from the burning of this refuse in a properly designed arrangement of destructor cells and boilers was founded on the supposition that only about one-third of the calorific value of the refuse would be utilized in the boilers, after due allowance had been made for the complete and perfect combustion of the ashbin refuse and its gases.

The plant consists essentially of a destructor house, in which is arranged a range of destructor furnaces, twelve in number, in two banks of six each, placed back to back, with the working floors in between. The destructor cells themselves are arranged a pair on each side of a Babcock & Wilcox boiler. Each of these boilers has a heating surface of above 1,400 square feet, and a pair of cells on each side of it are arranged to discharge their products of combustion under the boiler tubes immediately above the level of the fire-bars, these fire-bars being left in the boiler together with the fire-doors in exactly the same manner as if the boilers were being erected without the accompaniment of dust destructor cells. Each cell is arranged with double flues, one leading to the boiler, as aforesaid, and the other direct to the main flues.

Each destructor has a grate area of twenty-seven square feet. The main flues are arranged above the floor level and underneath the working floor, and are in duplicate, each boiler and cell being able to discharge its gases into either or both of the main flues. This arrangement of duplicate flues is essential in the combination of a dust destructor with an electric lighting station, as the dust carried over with the products of combustion from the cells into the main flue must be removed at moderately frequent intervals' whilst the working of the main flue can never be discontinued owing to the necessity of continuous steaming of the boilers, and this duplicate arrangement of the flues enables one flue at a time to be cleaned out, the products of combustion of all the boilers and all the cells being taken into the remaining flue during that time. At the end of the main flues is placed a chamber, which for the present will serve the purpose of a dust-depositing chamber, but may in the future be divided up to contain an economizer with its requisite by-pass flue. This chamber leads into the main chimney shaft, which is 150 feet in height from the floor level, and is provided with a circular gallery around its base, into which this chamber leads, and between which gallery and the main shaft are a number of small openings, the whole being so arranged that the products of combustion have to swirl round the gallery to enter the shaft—a provision to ensure the final depositing of any fine dust carried by the gases through the depositing chamber. The chimney shaft is lined right to the top with fire-brick, and a ventilated air-space left between the fire-brick lining and the main structure of the shaft, to avoid the outer walls being appreciably heated.

Each boiler has its proper complement of fire-grate, fire-doors, etc., which are provided for the express purpose of enabling the boilers to be fired by coal alternately or simultaneously with the absorption of heat from the waste gases of the destructor cells passing through the boilers. This arrangement fulfils a two-fold object. First, the provision of the secondary fire before referred to, which is in the most desirable position for further heating the destructor gases immediately they enter under the boiler, should that operation be requisite, and having the further advantage that the heat so produced is ultimately completely absorbed by the boiler and thus turned into profitable use ; secondly, to add to the steam raising power of the boilers when the heat of the destructor gases is not sufficient to produce all the steam required, or when the destructor cells attached to a particular boiler are out of order, to enable the boiler to be entirely fired by coal or coke.

Each of the destructor cells and the boiler furnaces is fitted with two systems of forced draught, one being an air blast, the other an induced blast produced by steam jets. The air blast is produced by three sets of fans coupled to and driven by electric motors, two out of the three fans being sufficient to supply 16,000 cubic ft. of air per minute, the maximum quantity that could possibly be required and to produce it at a pressure up to three-inch water-gauge. The steam blast is derived direct from the boilers, and is arranged as a continuous system, so that cells adjoining a boiler not in use can still obtain their steam blast from the other boilers in use.

Ten out of the twelve dust destructor cells are capable of burning with ease the 20,000 tons of ashbin refuse which have to be dealt with by the Vestry annually. The charging of the cells with refuse is to be effected in a manner which, though not novel, will perhaps be more effective than heretofore. The refuse is tipped from the carts into a tipping wagon, sinking below ground level and raised by the lifts afterwards to a floor considerably above the level of the tops of the dust destructor furnaces. These tipping wagons are then hauled by mechanical means into any desired position along the range of furnaces, and the refuse tipped from them into storage bins reaching from this floor to the level of the tops of the destructor furnaces. From these storage bins the refuse is discharged as required into charging trucks, divided into compartments so arranged that the charging truck being brought over a horizontal door in the top of and at the back of the destructor cells, doors in the bottom of the truck may be opened simultaneously with the door at the top of the cell, and the exact charge of refuse dropped through in the cell. There it falls upon an inclined hearth at the back of the fire-grate, whence it is raked down through the clinkering doors in front on to the fire-grates themselves.

As mentioned previously, the principal object of the whole of this arrangement of boilers and cells is to get the maximum output of steam. I have calculated that the electric light station will require steam at 120 lb. pressure at the rate of 12,000 lb. per hour for four hours a day, 6,000 lb. per hour for three hours a day, and 2,000 lb. per hour for the balance of the twenty-four hours, or in all 100,000 lb. weight of steam for twenty-four hours.

The contractors who tendered for the carrying out of the works were invited to state what proportion of this weight of steam they would guarantee should be raised by the consumption of ashbin refuse only. Many of them undertook that no coal should be required to raise the requisite amount of steam daily. It must be borne in mind that the chief difficulty to be met in the combination of a dust destructor with an electric lighting station, from a steam-raising point of view, is that while the refuse is being burned at an approximately even rate during the whole day the steam for the electric light station unfortunately is required in very varying quantities, varying from a very small quantity during the greater portion of the day to a maximum, at least six or seven times the minimum, during the four hours of heavy load ; and whilst the furnaces might be quite capable of raising the total quantity of steam required at an even rate, they might be incapable of raising the quantity required during the four hours of heavy load. To meet this difficulty, it is proposed to install in conjunction with the boilers the Halpin thermal storage system. Seven reservoirs, each 35 feet in length and 8 feet in diameter, are provided and connected up to the boilers, thereby accumulating the energy. The temperature in the reservoirs is never allowed to drop below the equivalent of 120 lb. steam pressure to the square inch, but, during the accumulation of the energy developed by the boilers, the temperature is raised in both the boilers and these reservoirs until a temperature equal to a pressure of 200 lb. per square inch is attained. When in each day the time of heavy load is attained at the central station both the boilers and these reservoirs feed into the steam mains supplying the engines, and as the energy taken by the engines considerably exceeds that which the boilers are capable of generating, the pressure in both boilers and reservoirs gradually falls until a minimum of 120 lb. is again reached, and the energy represented by this difference in temperature is that which has been taken up from the boilers during the daytime by the thermal storage reservoirs. Thus is the energy, that would otherwise be wasted, accumulated and carried on to the time when it can be utilized by the electric light engines. An additional and not unimportant advantage accrues from the use of these thermal storage reservoirs, inasmuch as the feed water is pumped into the reservoirs and not into the boilers, and hot water at the actual boiler pressure is allowed to gravitate from the reservoirs into the boilers to make up for the evaporation in the boilers.

It has been stated that higher pressures than 70 lb. or 80 lb. cannot be attained in boilers fired with destructor gases. Statements of this kind do not require much comment from me. It will be obvious to all of you that with destructor gases varying from 1,200° to 2,000° Fahrenheit, such a pressure as this, or, indeed, if it were desired, a much higher pressure of steam, can be obtained. Perhaps those who have made such statements will be reassured when they find a firm of standing guaranteeing, under the heavy penalties, the successful issue of a dust destructor thermal storage scheme in which a pressure of 200 lb. to the square inch has to be attained without the use of coal.

A somewhat similar system is about to be erected now under my superintendence for the Corporation of Swansea, the chief differences in this scheme being that only eight in place of twelve destructor cells are being put up, with four boilers each, however, in this case with a total heating surface of 2,896 square feet. No thermal storage cylinders are for the present being connected to this installation, though provision is being made for their addition at a future date when the load on the station makes it desirable. In this case, also the electric lifts are not being used, as the general configuration of the site allows of an easy inclined roadway being constructed for the up load. In all other respects the installations are almost identical.

About a year ago I informed you that a project was on foot by which the Swansea Corporation hoped to be enabled to supply all the tramways within their own town with electricity generated at their own electric lighting station. This has now become a definite scheme. The Tramway Company will ultimately have about twenty-five cars simultaneously in operation, and these cars will between them run annually an estimated car-mileage of 1,000,000. An electric tramcar takes in an average town a B. O. T. unit for each car mile run, and therefore the output of supply to the Tramway Company will be one million units annually. On the basis of the arrangement proposed between the Corporation and the company, it is estimated that the latter will be supplied with current about 1½d. per B. O. T. unit conditionally upon the supply being made only during 20 hours of the day instead of 24, the other 4 hours being those of the heavy lighting load, and to carry the Tramway Company over this period a stationary battery of accumulators will be installed of sufficient capacity. The revenue from these million B. O. T. units represents a sum exceeding £6,000 annually, and it is remarkable that it will be earned with one plant running during the day and late at nighttime with an output of about 200 kilo-watts. In other words, it will be earned by the same machinery that would in any case be running during the hours of daylight to keep the mains charged, and earning practically no revenue. It follows also that the cost of producing this extra million B. O. T. units will be only some additional oil used on the engine owing to its running at full load in place of at an extremely light load, no further charges for attendance, and possibly but a small extra amount annually for repairs, though this is doubtful.

---

* Abstract of paper read before the Northern Society of Electrical Engineers, England.

Since, therefore, the whole of this large output is produced at an extremely low additional cost, the station and destructor can be run, paying all its maintenance charges, as well as interest and sinking fund for the production, not only for the million units per day load, but of 350,000 units for public and private lighting, and the cost of attending to the public arc lamps at no extra cost, leaving the revenue derivable from these sources as net profit. It will therefore be feasible for the first time in this country to sell electricity for private lighting purposes at two pence per B. O. T. unit and to make no charge for the current used for public lighting purposes. I need hardly point out to you that with gas at 3s. 6d. per thousand cubic feet, electric lighting will under these conditions be much cheaper than gas. Had the Corporation to pay for the fuel, their cost of production, with the stoker's wages, would be raised by nearly one penny per unit. This would then raise the price of the supply of current to the Tramway Company to a point at which it would be more profitable for the latter to erect their own generating station. The successful combination of dust destructors with electric lighting is in this way likely to produce a complete revolution in the prospects of electric lighting in this country.

EUROPEAN INCANDESCENT LAMPS.

Supplementing the tables founded upon the tests of European incandescent lamps made by Mr. D. Paisley, London *Industries and Iron*, has published considerable data which serves to illustrate the cost per candle power of the chief English and foreign lamps. In ELECTRICITY for December 18 the table showing cost of 16 C. P. lamps was reproduced. The following shows the cost for 8 C. P. lamps :

Name of Maker.	Av'e C. P.	Watts per C. P.	Price.	Cost per C. P. for 600 hours in Pence.
			s. d.	
Gabriel & Angenault, Paris.	8.7	3.68	1 0	14.61
Stearn	8.7	3.83	0 11½	14.68
Constantia	7.66	3.83	0 7½	14.74
Gebruder Pintsch	8.98	3.91	1 0	15.40
Allgemeine Company	6.9	4.12	1 0	16.56
Daylight	7.66	4.34	0 7½	16.57
Brush Company, Vienna	8.00	3.94	1 0	16.66
Pope & Goosens	7.83	4.31	0 9½	16.77
Siemens & Halske	8.23	4.41	1 0	17.41
Robertson	7.96	4.81	1 4	17.52
Hard	7.1	4.43	0 10	18.16

Ediswan (New)	7.26	5.24	1 9	21.45

The Storage Battery.*

A DISCUSSION OF ITS APPLICATIONS BY THE MEMBERS OF THE A. I. E. E.

THE STORAGE BATTERY OR THE GAS ENGINE AS AN AUXILIARY.

BY NELSON W. PERRY, E. M.

DISCUSSION (*Concluded*).

Mr. Perry—Mr. Appleton speaks of the peak of the load requiring in the neighborhood of 400 horse-power. The largest gas engine so far constructed, so far as I know—single cylinder gas engine—is of 375 horse-power, with fuel gas ; with illuminating gas it will go something over 400, perhaps 450 horse-power, and it has been repeatedly stated by English manufacturers that they were ready to make gas engines in 1,000 horse-power units whenever wanted. But it is customary, I understand, when the large units are employed, to use two-cylinder gas engines, so that we may have, for instance, an engine of two cylinders, each of which would separately give 200 horse-power, and the explosions are so timed as to give an explosion once every revolution. Then in regard to the transmission of power by means of gas to an outlying station, Mr. Appleton suggested that we have the copper mains also. My idea was to supplant the copper mains with the gas mains, and while I suggested a six-inch pipe, that was assuming that we required that power continuously. With the storage battery the claim is that we may use a smaller conductor, and by charging for a long time we can store up a large amount of energy to use when the demand is excessive. The same would apply to gas storage. In regard to Mr. Blizard's remarks—in reading a paper before the National Electric Light Association at Cleveland I was jumped on by a member of "the leading storage battery company of this country" for some of my remarks in regard to the storage battery at that time. He distinctly stated at that time, if I recollect his remarks, that the cost of maintenance, guaranteed charges, was 10 per cent. on the *price* of the battery, and this letter that I referred to and the catalogue—the catalogue was the one in force at that time—contradict that statement flatly. This is the first opportunity I have had of replying to it. I have seen a later catalogue since that, and this also bases the guarantee on the catalogue prices. I also have in my possession the letter to which Mr. Blizard referred, but which I have not copied here. That letter, as I recall it now, is less specific than this one —this one being very specific, as it states here : "We send you by to-day's mail our illustrated catalogue, and would especially call your attention to the question of maintenance as contained on page 11." That seemed to be very specific as to what their guarantee means. Their guarantee was on the catalogue price and not on the cost price ; and at that time and in that place it is stated that : "In all cases of renewal by contract, the old material becomes the property of the company and must be returned to their works free of charge for carriage or packing." Now the omission of that statement from the new catalogue does not convince me that they do not expect that. I know from the experience of some others—not my own experience—that when you ask for a battery for some particular purpose where the discharge is pretty rapid, or for some very unusual use, the guarantee which they offer you, or that they print in their books, or that they talk about, no longer holds. They want a very much larger price for their battery, or their guarantee will be very much less favorable. And I admit that it is perfectly proper that they shall protect themselves ; that that battery shall be used under certain conditions and in certain ways. They cannot guarantee a battery, or a steam engine, or anything else that is improperly used. But what I maintain is that it is not economical under most conditions of central station practice, or at least where the demand is somewhat excessive in the way of discharge, to use the storage battery; that their prices are put up so high in order to give them a safe guarantee.

Mr. E. T. Birdsall—In regard to Mr. Perry's figures on the transmission of gas, he omits several important factors in the transmission of gas for that distance. In New York the subways are ventilated by pumping air through pipes, and they find that the loss of pressure per mile of 8-inch pipe, when delivering 12,000 cubic feet per hour, is 11 ounces per square inch. That is, starting with 16 ounces pressure, at the end of one mile the pressure is reduced to two ounces. That means considerable power is used to pump that gas along, and that should be counted in the cost of transmission. Another factor is that the friction in the flow of gas in pipes depends greatly on the number of bends in the pipe ; if it had a large number of bends or elbows, it would make a vast difference. A third factor is the leakage factor. Every gas company in New York, except possibly the latest one, which has new mains, figured that the loss of leakage at the joints is about 10 per cent., and in that the loss of pressure in the electrical conductors is balanced at once.

In regard to the reason why batteries are not used more universally, it has always been my opinion, as the result of considerable experience, that all the first plants were too small for the work they had to do. But this has been the great difficulty : a man would put in a battery, and as a rule it would be about one-tenth of the size necessary to the work, and the battery would fail in six months; and all batteries were the same in his eyes after that. In regard to guarantees, it is my present practice not to call on the companies for guarantees where I am reasonably certain of having a chance to look after the plant once in a while. The only experience I had with guarantees was not successful—the company failed before we had a chance to call on them.

Mr. A. E. Childs—Mr. Edgar in his remarks spoke of the value of his battery in cases of rapid changes of weather. I was in Boston one day in September, and I happened to be in an office taking light both from his company and from the alternating current company in that city. At three o'clock a very black cloud passed over the city, and inside of five minutes possibly every light in Boston that was ordinarily in use was turned on, and there is no doubt that inside of five minutes Mr. Edgar's station had on its maximum load. His lights were absolutely perfect ; there was no diminution in voltage. The lights were steady, without a single flicker. The lights in the adjoining office were low ; they were like red-hot hair pins, and were flickering.

Referring to Mr. Hering's communication, we find that he states that "a purchaser will believe you if you admit that the life of the perishable parts will be comparatively short, but he will not believe you if you say it will be long, even if you are telling the truth. Later on he states that you may as well recognize that the life of a positive plate is short, and therefore you may as well build a battery that has a positive plate with a short life. It seems to me that Mr. Hering is working to satisfy the popular demand. He wants to produce a battery which has a short life, so that when he goes to a man and tells him he has a battery with a short life he will be believed. He does not want to produce a battery with a long life, for he is afraid people will not believe him when he brings it forward.

I would like to ask Mr. Hering what he means by one trip. It may be one mile, or it may be 20 miles, or it may be 50 miles.

Mr. Perry states that he would not recommend storage batteries under any circumstances, but that he has a still more economical method, and he proposes to use the gas engine for a purpose for which none of us, I may venture to say, have ever seen it used before, and he states in the most positive language that it is a more economical method. I would ask him to refer to even one central station using gas engines to take the peak of their load.

---

* Abstracts of communications read at the 101st Meeting of the American Institute of Electrical Engineers, New York and Chicago, November 20, 1895.

Referring to his remarks on the guarantee which he describes here, of June, 1894, Mr. President, the world has progressed a great deal in the last eighteen months, and if Mr. Perry, knowing that his communication was to be read to-night, had taken the trouble to inquire what guarantees he could obtain to-day and not last June twelvemonth, he would be able to find that the companies supplying batteries could guarantee to him a specific percentage depreciation on the cost of the elements, and not on the complete plant installed. He would be able to find that the rate at which the depreciation goes on was guaranteed to be very small. It is astonishing, sir, to me at least, that a man will bring forward such statements as those 16 or 18 months behind time.

In conclusion, I would state that the storage battery seems to call forth from engineers more prejudice than any other class of apparatus. It is my experience that certain engineers will tell you inside of 15 seconds, if you broach the subject to them, that they know all about storage batteries; that they do not want them at all, at any price; that they wouldn't have them if you gave them to them. If you put up a guarantee with Government bonds at the back of it, they would not look at it. We ought to expect from them a better spirit with regard to storage batteries, and that when they are approached on the subject of applying storage batteries to their central stations they ought to take the matter in a spirit of investigation; and I am not wrong in saying that at present a large majority of them will not even consider the storage battery. They think they know all about it, and they think they know it would be of no use to them.

Mr. Carl Hering—Mr. Childs asks what is meant by one trip. One trip is the distance a car travels from one power house to another or back to the first.

Mr. Childs—May I be allowed to ask Mr. Hering what the length of his trip is?

Mr. Hering—The length of a trip, of course, may vary very greatly. What I wished to emphasize in the paper was that the best possible arrangement of a plant would be to use a battery which will discharge in one trip whatever the length of that trip may be; whether the trip is one of a few miles or of a hundred miles, the battery should be adapted to it. As a rule, the trips of a car in an ordinary city are comparatively short, much shorter in time than what would correspond to the "excessive" rate (four hours) of discharge of a certain well-known accumulator; there are very few cars in use the length of whose trips, in time, is four hours or more.

The Electrical Exposition of 1896.

Mr. Clarence E. Stump, who is so well known in the electrical field, has been appointed General Manager of the Electrical Exposition which is to be held in New York City beginning May 4 and continuing until the 1st of June.

Numerous inquiries for information regarding space and other details are daily being received by the management, and a large number of prominent manufacturers have already closed contracts, while many additional firms have signified their intention to make extensive exhibits. The success of the enterprise is assured, and all indications point to the largest and most interesting display of electrical apparatus and supplies ever made in this country.

Storage Batteries for Traction Work.

The mention of battery cars has a tendency to make an electrical engineer's mouth water, but hitherto they have done little else than make his eyes weep. The long-looked-for and hardly-striven-for has not yet come, at any rate in this country, and, what is even more depressing, does not give any very notable promise of coming. Electrical industry has yet to produce a battery commercially adapted to the conditions of traffic on common roads and tramways. The non-existence of such an appliance is, we do not hesitate to affirm, one of the most serious hindrances to electrical progress, possibly the most serious of all; and, conversely, its advent will open up an immense field of electrical applications which cannot now be attempted. Yet, though a really commercial traction battery cannot be said to exist, and though the direction from which it may come is not very clearly defined, we should not care to assert that the outlook is quite hopeless. The storage battery of today is less imperfectly adapted to this class of work than the battery of a few years, or even of only one year ago. Structural difficulties and mechanical imperfections are being overcome gradually by the practical manufacturers, while we hope the researches of many electro-chemists who are engaged in this problem will help things forward on the more scientific side.—*The Electrician* (London).

London Notes.

(From our London Correspondent.)

VERTICAL EARTH-AIR ELECTRIC CURRENTS.

Before the Physical Society (London) on December 13 a contribution by Prof. A. W. Rucher was read on the subject of "Vertical Earth-Air Electric Currents in the United Kingdom." Before the British Association meeting at Oxford, a year or so ago, Dr. Schmidt stated that he had expanded the components of the earth's magnetic force in series, and had deduced expressions two of which give the magnetic potential on the surface of the earth in so far as it depends on (1) internal and (2) external forces. The third series represents that part of the magnetic forces which cannot be expressed in terms of a potential, but must be due to electric currents traversing the earth's surface. Dr. Schmidt concluded that such currents amount on the average to about 0.1 ampere per square kilometer. Prof. Rucher has tested this conclusion, drawn from the state of the earth as a whole, by means of an examination of the line integral of the magnetic force taken round a re-entrant circuit in the United Kingdom. The results arrived at by the author upon stated selected circuits, calculated upon data obtained from 1886 and 1891 surveys, lead him to the conclusion that there is not, in the United Kingdom at any rate, a vertical current amounting on the average to 0.1 ampere per square kilometer.

ELECTRIC SIDE LIGHTS.

The question of screening ships' side lights has been under consideration at the Board of Trade. The deliberations of the officials have ended in instructions being sent out to the Board's surveyors to the effect that in the case of electric lights the forward edge of the screen, or chock on it, should be in a line parallel to the keel with the inside edge of the filament. The breadth of the filament is not to be more than two inches, nor less than one inch, measured at right angles to the fore-and-aft line of the ship.

HORSELESS ROAD CARRIAGES.

During the past few months there has been spreading a very necessary agitation on the part of the press and the general public to have amended the legislation which at present so absurdly prevents the use of horseless carriages upon our streets. The present Parliament will most likely revive the bill introduced by the late Government. The Board of Trade is being memorialized to take the matter in hand. A large public meeting has been held in London and an Association formed to see that there is no unnecessary delay in getting matters righted, and Sir David Salomons, an amateur electrician of some note, has accepted the presidency of it. Test cases are being tried in various parts of the country, but in every case so far the magistrates have decided that the steam, petroleum and similar carriages are locomotives within the interpretation of the Locomotive acts. In certain quarters it is thought that these horseless carriages will develop into an immense industry once reasonable legislation is passed. Unfortunately, electricity in this application has been occupying a back seat during the agitation. Mr. W. Worby Beaumont took the subject of "Mechanical Road Carriages" for a series of Cantor lectures just concluded before the Society of Arts, but electricity had little place, for the subject was treated more from the standpoint of the general engineer than from any other. Another paper delivered before the Society of Arts was by Mr. H. H. Cunynghame, on "Locomotive Carriages for Common Roads," but in the course of the discussion which followed the complaint was made that "electricity had been eliminated" from the paper.

Legal Notes.

A petition has been filed in the United States Court at Milwaukee, Wis., praying for the appointment of a receiver for the Central Wisconsin Electric Street Railway Company. The company is located at Oshkosh, where it owns valuable franchises, but has not yet begun operations beyond the laying of two miles of track. The plaintiffs in the suit are C. E. Loss and Philip J. Partenheim of Chicago, who allege that the company is indebted to them in the sum of about $16,000, and among the defendants named is J. K. Tillotson. The bill of complaint goes quite extensively into the history of the attempts to secure the franchise and the consequent workings of the company. The bill alleges that a large quantity of steel rails was purchased from the petitioners to be used in the construction of the road, and which have accordingly been laid on streets in the city of Oshkosh. The amount due has not been paid and the rails have been attached. Judgment is asked, together with the appointment of a receiver and the sequestration of the property.

The suit of Mrs. Clark, of Middletown, N. Y., against a traction company running a line from that city to Goshen is an important one, as the matter affects many trolley companies in the State of New York. The plaintiff wants damages for running trolley lines over her property without first obtaining her consent to do so. The property in question is at Wickham avenue and North street., Middletown. The defendants set up the claim that in using the land they were sustained by the statutes. Judge Brown, at Newburg, on the 26th ult., declined to hear any argument on the law in the case, directing the counsel to put in their briefs as soon as possible. The Court said that if the tracks of the company had been laid in the middle of the street there would have been no cause of action. This would have had a tendency to discourage the bringing of similar suits. As it was, however, the Court said, the plaintiff was entitled to recover damages, the amount of which is to be determined later.

Chancellor McGill, of New Jersey, has appointed Mr. J. D. Bennett of Brooklyn receiver of the Rockaway Electric Light Company, a corporation which lights Rockaway Beach. The liabilities are about $100,000 and the assets are $15,000.

Original Electrical Investigations at Columbia College.

In the laboratory of the department of Electrical Engineering at Columbia College, New York, a number of investigations of an advanced and purely scientific character are now in progress. This work is in charge of Prof. M. I. Pupin who has recently completed some interesting investigations of the transmission of long electrical waves, the results of which will soon be published. Several candidates for the degree of Ph. B. are conducting special investigations. M. R. Rittenhouse, a graduate of Stevens Institute of Technology and the Electrical Department of Columbia, and at present holder of the fellowship in electricity, is investigating the magnetic behavior of iron when subjected to rapidly alternating currents. At the next annual exhibition of apparatus to be given by the New York Academy of Sciences, next March, when the original work done by the members of the society during the preceding year will be illustrated, Prof. Pupin expects that his department will have an important exhibit.

GENERAL NEWS.

What is Going On in the Electrical World.

Windom, Minn.—The water works and electric light system which is being put in here is nearing completion.

Somerville, Tenn.—A. J. Rooks, of this place, wants to correspond with dealers in reference to storage batteries.

Beatrice, Neb.—A special election will be held here to get the public vote on an issue of $15,000 bonds for an electric light plant.

Union, S. C.—The city council is considering the question of a bond issue of $40,000 for waterworks and an electric light plant.

Dublin, Ga.—An election will be held on the 11th inst. to vote on the proposed issue of $25,000 in bonds for water-works and electric lights.

Amherstburg, Can.—George M. Winn has been granted a franchise to establish an incandescent electric lighting system in Amherstburg.

Rockford, Ill.—The aldermen have passed an ordinance appropriating $70,000 to build, equip and maintain for one year an electric lighting plant.

Greenville, S. C.—The Greenville Electric Light Company, S. C. Hamilton, Jr., manager, needs an electric-light plant of 35 arc and 400 incandescent lights.

Appleton, Wis.—The Citizens' Electric Light & Power Company has filed an amendment to its articles of incorporation increasing its capital stock to $30,000.

Chattanooga, Tenn.—The sale of the Chattanooga Electric Railway, on petition of the second mortgage bondholders, has been postponed to the 24th of February next.

San Leandro, Cal.—At the recent election there was a large majority vote in favor of the proposition to issue $10,000 of bonds for the purpose of establishing a municipal lighting plant.

Hillsboro, N. C.—Webb & Co., of Hillsboro, will next month begin the erection of a cotton mill at that place and will equip it with an electric light plant as soon as the buildings are completed.

New York.—The Eighth Avenue Railway has been leased to the Metropolitan Traction Company, and there is a probability that within a year the road will be changed to a conduit-electric line.

Elgin, Ill.—The Elgin Electric Illuminating Company has made an assignment, naming J. B. Dick as assignee. Mr. Dick estimates the assets and liabilities, in round numbers, at $20,000 each.

Youngstown, O.—Daniel Moynahan, who purchased the Niles and Mineral Ridge electric railway, has decided to extend the line to Youngstown and work will be commenced upon the extension in a short time.

St. Paul, Minn.—It is thought that the outcome of the meeting held here recently by a number of physicians to discuss the organization of a school of medical electricity will be the establishment of such a school.

Woburn, Mass.—It is understood here that the North Woburn Street Railway has been sold to a syndicate of which State Treasurer Shaw is the head. The road will be converted by its new owners into an electric system.

Alliance, O.—The Pennsylvania Railroad Company intends to erect an electric lighting plant to furnish the lights needed in its yards and buildings here, which have been heretofore lighted by the Mutual Electric Light Company.

Brainerd, Minn.—At the election held recently to determine the question of selling the city electric light plant to C. N. Parker, of Brainerd, and E. C. and P. A. Gibson, of New York, the proposition was carried by a vote of 723 to 143.

Columbia S. C.—Dr. W. C. Black, of Greenville, and associates, are organizing a stock company for the purpose of building a cotton mill on Broad River, S. C., which will include in its equipment an electric light plant of several hundred lights.

Staten Island, N. Y.—The New Brighton Light, Heat & Power Company, lately organized, will apply to the trustees of New Brighton for permission to string wires in that town for the purpose of supplying light and power for public and private use.

Portland, Conn.—A representative of the Connecticut Engineering Company of Norwich has been in Portland inspecting the plant of the insolvent Portland Electric Light Company, and it is said the Engineering Company is negotiating to purchase the property.

Kenosha, Wis.—G. R. McDonald, S. C. Newman and W. W. Strong, acting for Chicago parties, have filed articles incorporating a new electric light and power company for this town. They bought the plant from the old company. The new company will petition for a new franchise.

Amherst, Mass.—Meetings have been held lately at North Amherst and Sunderland in the interest of the proposed electric road to Sunderland and financial support was promised in both places; the desire to have the road is general along the proposed route and there is no doubt that it will be built.

Plainfield, Conn.—At a meeting of citizens held here last week a committee composed of Ira F. Lewis, Dr. G. H. Jennings and Charles H. Ray was appointed to assist the warden and burgesses to see about lighting our streets by electricity and report at a future meeting.

Chester, Pa.—The Citizens' Electric Light Company, which furnishes light to the borough of Clifton, Lansdowne and Sharon Hill, will have a competitor in the Llanerch Electric Light Company. An ordinance has been passed by the Lansdowne council giving the Llanerch company the right to erect poles and string wires.

Norfolk, Va.—The contractors for the building of the new Portsmouth electric street railway will begin work immediately. Messrs. Troft and Burns, representing the contractors, Belden & Seeley, are making preparations to start. The poles are expected to arrive at any time, and the building of the road now seems an assured fact.

Sheffield, Ala.—The Consolidated Water & Electric Light & Power Company has been organized here with a capital stock of $250,000. The following are the directors: E. F. Enslen, C. B. Ashe, L. A. May, F. V. Evans and W. R. Brown. E. F. Enslen of Birmingham was elected president and C. B. Ashe of Sheffield secretary and treasurer.

Reading, Pa.—The Union Traction Company, which was granted a charter at Harrisburg a few days ago, will control the Reading Traction Company, the East Reading Railway Company and the Reading and Womelsdorf Electric Railway Company, which together occupy nearly sixty miles of electric road. James A. O'Reilly is president and Wm. R. McIlvaine secretary.

Pittsburg, Pa.—At a meeting held in this city on the 23d ult. a combination of the leading street railroads was effected, to be known as the Consolidated Traction Company. The new organization will be controlled by the Widener-Elkins syndicate that brought about the combination of the Philadelphia roads. The capital stock of the consolidation aggregates $10,400,000.

Mt. Clemens, Mich.—Three electric railroad corporations have applied for franchises for a line to Detroit by way of Harrison and Erin and are seeking to gain right of way around Grosse Point. The probability that a railway will be built through the section has boomed real estate at Lakeside and Hamtramck, where Detroit and Mt. Clemens parties intend to erect a number of summer homes.

Watertown, N. Y.—It is proposed to utilize the water power of the Black River in generating electricity for power and lighting purposes in this city. A plant will be established at the old Lance woolen mill site, where there is available water power. Wires will be run across the river from the power station to the different manufacturing plants, which will be equipped with suitable electric motors.

Seattle, Wash.—A deal has been consummated here involving the purchase of the Seattle Gas and Electric Light Works by a party of Minnesota capitalists, headed by Samuel Hill, of Minneapolis, president of the Eastern Minnesota Railroad Company. The new board of trustees will consist of Samuel Hill, W. J. Murphy, W. H. Dunwoody, Horace Henry, all of Minneapolis, and W. H. Cannon, of the Chase National Bank, New York.

Fort Wayne, Ind.—The entire street car system of this city is to be improved by the Cleveland syndicate who have obtained control of the properties. The capitalization of the new company is $1,500,000, and a mortgage of $1,500,000 has been filed to cover the bonds of the company. John J. Shipherd, of Cleveland, is the leading spirit in the new organization, which will be known as the Consolidated Electric Railroad Company.

Hagerstown, Md.—The Harrisburg Construction Company, which has the contract to build the road for the Hagerstown and Potomac Electric Railway, has closed the deal with the Martinsburg Street Railway Company and purchased for $10,000 the plant of the latter company, consisting of three miles of track, with the rails, motor cars, trailers and other equipments, which will be used in the construction of the Funkstown and Leitersburg extension.

Blairstown, N. J.—The dynamos of the new electric light plant, just finished, are run by water power from the flouring mill at Paulina, two miles away. The entire expense of the work, amounting to nearly $50,000, has been assumed by John I. Blair, the multi-millionaire, of this place. He will give a deed for the plant, together with the valuable mill property, to the Blair Presbyterial Academy, which he has already endowed to the extent of $600,000.

Albany, N. Y.—The State Railroad Commissioners have granted permission to the Syracuse and Oneida Lake Electric Railroad Company to build an eleven-mile railroad from the boundary line of Syracuse to Oneida Lake. They have also granted the petition of the Fulton and Oswego Falls Street Railway Company to increase its capital from $15,000 to $100,000, and the petition of the Corning and Painted Post Railroad Company to change its motive power to electricity.

Providence, R. I.—The Providence & Taunton Street Railway Company has been organized with a capital stock of $30,000. The proposed railway is to connect Providence and Taunton and indirectly Fall River and Providence. Its length will be about 11 miles. The present directors are: Earl H. Potter of Seekonk, Reuben Bowen of Rehoboth, N. A. Walker of North Dighton, J. A. King of Seekonk, F. E. Perkins and W. B. M. Miller of Providence, and Peter H. Corr of Taunton.

Raleigh, N. C.—A small cotton mill will be built early in the coming year at a point five miles north of Raleigh, by John C. Drewry and associates. When completed it will probably be equipped with an electric light plant. —The Capital Club, a politico-social organization of business and professional men of Raleigh, will soon begin the erection of a new club house, which will be equipped with all the latest electrical devices used in such an establishment, such as call-bells, electric lights, etc., etc.

Buffalo, N. Y.—The Buffalo Traction Company after a prolonged contest has finally been granted a franchise by the board of aldermen. The franchise gives the company the right to use a number of the city's streets for the operation of a new electric car line. Herbert P. Bissell and Tom Johnson, of Cleveland, O., are among the prominent men connected with the company. The Traction Company a few days ago purchased the Buffalo, Kenmore and Tonawanda Electric Railway in order to get a connection to Tonawanda.

Washington, D. C.—Mr. Benedict, the Government printer, in his report says: "The utilization of electricity as a motive power is an important step in connection with the work of the office [Government Printing Office]. Electricity applied to machinery has been found to be not only very economical, but a great advantage and convenience. Its easy adaptation to the varying speeds required by printing machinery, its safety and the ease with which it may be produced and controlled are all points in its favor."

St. Joseph, Mo.—Every railroad car loaded with live stock on arriving here has to be weighed at the railroad yards and then rushed over to the stock yards and unloaded and the empty car switched back and reweighed before the farmer can know what his freight charges will be. In order to facilitate this operation all of the railroads are quietly putting in electric scales at their yards. These scales will catch and register the weight of a car almost as quickly as the cumbersome weights could be picked up under the old system.

Cripple Creek, Col.—Arrangements have been completed for building an electric road from Cripple Creek to Canon City, over a route about 26 miles long, and work will begin the middle of January. J. H. Peabody, who represents the people behind the project, says: "The completion of this road and the building of the Denver and Cripple Creek short line, will bring Canon City from forty to sixty miles nearer Denver, and will give Denver that much shorter line to the great grain fields and coal mines of the Canon City district. At present Canon City comes to Denver around by Pueblo and Colorado Springs, 161 miles. By the new route this would be cut to 100 or 115 miles."

Milwaukee, Wis.—Judge Jenkins has appointed Frank M. Hoyt special master to take charge of the sale of the Milwaukee Street Railway. The sale will take place some time in February. No bid will be accepted, under the orders of the court, for a sum less than $5,000,000, and it is inferred that only one party wil be in position to buy it—the reorganized Milwaukee Street Railway Company—which will offer the old bonds and stock of the company as purchase money, or even a cheek secured by those bonds and stock. The officers of the reorganized company are: President, William Nelson Cromwell; secretary, C. A. Spofford; treasurer, A. Marcus; purchasing agent, C. L. Jones, all of New York.

Stockton, Cal.—Much of the power used at the various mines in this section to operate the machinery is water power, and some of the mines have had to stop work lately owing to the lack of sufficient water. Under this condition of affairs the mine-owners have come to the conclusion that where the water cannot be brought to them by flumes and ditches they must go where the water is, and by generating electricity utilize the power at points to which the water itself cannot be taken. The App mine, at Jamestown, is arranging for an electric plant; the Rawhide mine will use the same power plant. The Utica mine, at Angels, which has suffered greatly from scarcity of water at different seasons, will soon commence work on the largest mine electric system to be found in California. Electricity has superseded candles in most of the mines.

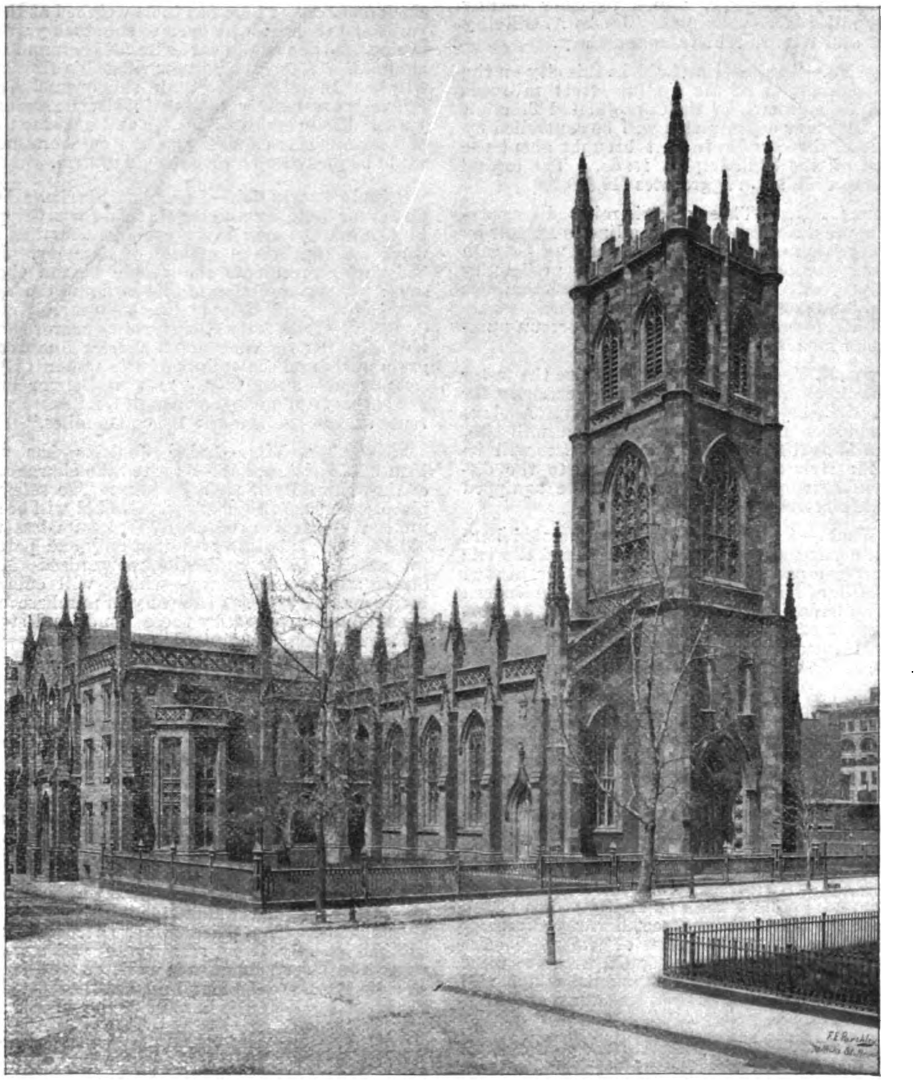
Fayetteville, N. C.—James H. Holt & Sons, last week began the erection of a $300,000 cotton mill in this city. The senior member of the firm tells a representative of ELECTRICITY that it is their intention to equip the factory with one of the best electric light plants that can be secured, of about 1,000 light capacity. The same firm own six cotton mills at Burlington, N. C., which is their headquarters, one of which has no electric lighting facilities, and it is the intention to put in a small electric light plant at this mill also in the near future. —Ex-Governor Thomas M. Holt, of Haw River, N. C., Benj. N. Duke, of Durham, N. C., and associates, will, during the approaching spring, begin the erection of a large cotton bleachery, to cost $1,000,000, at Fayetteville. A feature of the establishment will be its electric light plant and other electrical apparatus. No contracts for anything connected with the establishment have yet been given out.

Philadelphia.—The amount named in the ordinance for electric lighting is $751,000, or $75,000 less than the companies offer to light the city for during the next year. As a consequence, the department of public safety appropriation ordinance for 1896 remains unpassed by select council, and unless the electric light companies reduce their bids for lighting the city so as to bring their estimates within the amount named in the ordinance, the electric light item is likely to be stricken out and the bill passed without it.—Municipal ownership of street railways was unanimously recommended at a meeting of the Citizens' Committee of Twenty-one, authorized at the great mass meeting at the Academy of Music on December 5. The committee also urged the importance of securing the nomination of councilmanic candidates who will favor the purchase of street railways by the city, and an executive committee was empowered to draw up a form of declaration to which candidates for council will be asked to subscribe.

Baltimore, Md.—The Maryland Electric Company and the International Telegraph District and Construction Company have been consolidated and now form the Edison Electric Illuminating Company. It is the intention of the new company to enlarge the plant of the absorbed Maryland Electric Company and build another plant of equal capacity. The officers of the new company are: Alfred A. Glasier, president; E. S. Webster, vice-president; Nicholas P. Bond, secretary; J. W. Ellard, treasurer, and J. Frank Morrison, manager. Directors: Alfred A. Glasier, Nicholas P. Bond, Ronald T. McDonald, William Endicott, third, of Boston, Mass., Edwin S. Webster, J. Frank Morrison, J. P. Smith, J. Warren Ellard and Edward Duffy.

TWO INTERIOR CONDUIT INSTALLATIONS.

In the accompanying illustrations are shown two electric lighting installations, differing widely in character it is true, but neither is without interest to those who wish to keep in touch with latter-day improvements in the art.



OLD FIRST PRESBYTERIAN CHURCH, NEW YORK.

The Hotel Ford, Phœnix, Arizona, is a modernly designed and equipped hostelry, and enjoys the distinction of being the first building west of the Rocky Mountains to be equipped with interior conduit. For the lighting service, which consists of 200 lamps, iron armored conduit was used. For the annunciator service, brass armored conduit was used.

W. R. Norton, of Phœnix, was architect of the structure. The electrical equipment was installed by the Electrical Supply Company of Phœnix.

The Old First Presbyterian Church, at 5th avenue and 11th street, New York City, has recently been equipped with an electric lighting system possessing no particularly striking or novel features, but is an example of first-class work throughout. In the church proper and its accessory buildings 400 16-C. P. lamps have been wired on the interior conduit system, the brass-armored grade being employed. Current is supplied from the mains of the Edison Electric Illuminating Company.

Hatzel & Buehler, New York, were the electrical contractors.

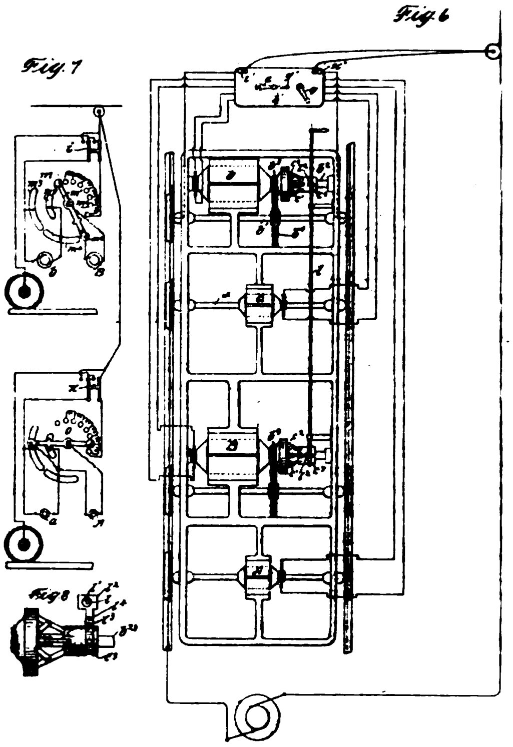
The Badt Electric Locomotive.

Under date of November 12, 1895, letters patent No. 549,485 was issued to Francis B. Badt, of Chicago, assignor to the Siemens & Halske Electric Company of America, for an electric locomotive which possesses many features of novelty. Having in mind the well-known fact that considerably more power is required to start a car or train from rest than is required when running at normal speed, the inventor has sought to overcome this objection by a method other than the employment of two motors adapted to be run in series at starting and then to be thrown into parallel for higher speeds. To accomplish this the inventor provides, in connection with each car or unit, two motors, one large motor, which he terms the "starting motor," having sufficient capacity to start the car in motion, and a small motor, which he terms the "speed motor," the capacity of which is sufficient to propel the car at normal speed. The two motors are mounted upon the axles of a single truck, the smaller motor being preferably mounted directly upon the axle without intermediate gearing, while the larger motor is connected to the other axle by means of intermediate gearing through a mechanical clutch by means of which it may be thrown into and out of gear.

When it is desired to start the car, the starting motor is thrown into gear to start the car in motion, after which the speed motor may be thrown into circuit to propel the car, the starting motor being thrown out of gear and disconnected from circuit. The speed motor may or may not be used to assist the starting motor, as may be desired. In order to avoid mistakes and render the operation certain, two operating levers are provided—one for the starting motor and the other for the speed motor—a lock being provided which prevents the movement of the operating lever of the speed motor beyond a certain point until after the operating lever of the starting motor has been moved to a position to cut the same out of circuit and disconnect it mechanically.

In connection with each car or unit, two starting-motor and two speed-motor switching devices are provided whereby the two starting motors may be connected first in series and then connected in multiple, after which the speed motors may be thrown into circuit, first in series and subsequently in multiple.

The inventor claims that by the employment of his invention high efficiency is obtained between stations, the two classes of work—starting and running at high speed—being done by different motors, each designed and geared for the highest economy and efficiency for the particular class of work. The capacity of the two motors combined is no greater than the capacity of the single motor as heretofore employed for doing the same work, and taking into consideration the simplified method of starting and operating, the first cost of the apparatus for an equal amount of work is not increased; the efficiency is greatly increased and the cost of operating decreased, while the fluctuations of the amperage at the power station are much smaller than in the systems at present employed.

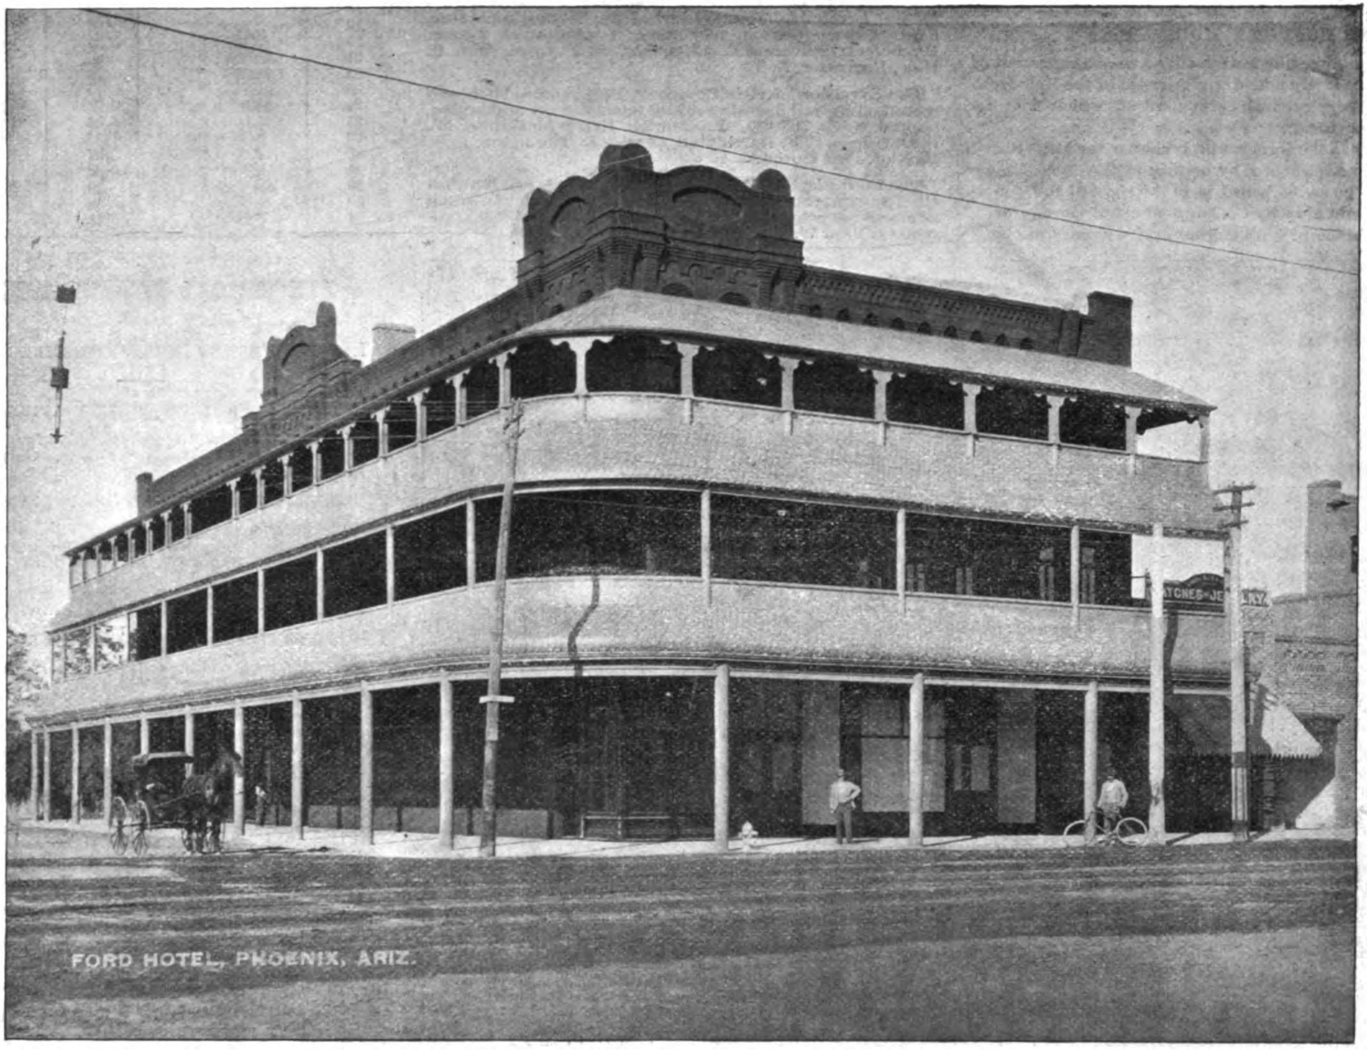


THE BADT ELECTRIC LOCOMOTIVE.

This form of locomotive is particularly adapted to heavy trains run at high speeds—as, for instance, where it is proposed to convert an existing steam road into an electric road. In applying this invention to such trains, it is preferred that a number of motor-cars in a train be attached to a single locomotive, say one motor-car to each three trailers, so that if a train should consist of twelve coaches three of them would be motor-cars and the other nine trailers. By distributing the weight necessary for the traction over a number of motor-cars, instead of having a single locomotive, a large saving is effected in repairs of the track, while in an elevated structure a large amount of money may be saved in the construction, as a lighter structure may be employed. By employing a system of electrical and mechanical connections between the first motor-car and the other motor-cars of a train, the motorman on the first motor-car may govern all of the motors on the train. The first motor-car alone may be provided with a trolley device, or each of the motor-cars may have its independent trolley.

Describing the invention in detail, reference is had to the accompanying illustration, in which Fig. 6 is a plan view of a car or unit provided with two starting and two speed motors, the circuit connections being illustrated in diagram. Fig. 7 is a diagram showing the circuit connections and switches for controlling the circuits through the several motors. Fig. 8 is a detail view of the clutch mechanism for controlling the starting motors.

The speed motor *a* is mounted upon one of the axles *a* of the car-truck, while the starting-motor *b* is connected with the other axle *b′* through intermediate gearing. As illustrated, the armature of the motor *b* is mounted upon shaft b^2, upon which shaft is loosely mounted a gear-wheel b^3, meshing with a gear-wheel b^4 provided upon the axle *b′*. A clutch is provided for connecting the gear-wheel b^3 with the axle b^2 or disengaging the same therefrom. The clutches are operated by means of a rotating rod *l*, carrying an eccentric *l′*, Fig. 8, opposite each clutch, the strap l^2 of the eccentric being mounted upon the end of a lever l^3, pivoted at l^4, and engaging by its end the sliding collar c^3, that controls the clutch. Two speed motors *a* A are also provided. As illustrated in Fig. 7, the starting motors *b* B are connected in circuit with a reversing-switch *i*, whereby the direction of the current may be reversed, and with a series-multiple switch *m*, whereby the motors may be first connected in series and subsequently in multiple. The circuit from one side of the reversing switch *i* passes to the terminal m^3 and thence to the motor *b* circuit, then extending to the terminals m^4 and m^5 One side of the motor B is connected with the arm *m′* and the other with the terminal m^6, carried upon the end thereof, but insulated therefrom. When the terminal m^6 rests upon the terminal m^4, the motors are connected in series, and when terminal m^6 rests upon the terminal m^3 the motors are connected in multiple. The rheostat-terminals m^2 are preferably arranged so that as the arm is moved resistance is first cut out, step by step, after which the circuit arrangement of the motors is changed from series to multiple, and as the arm continues its movement, further resistance is cut out step by step. The speed motors *a* A are likewise connected in circuit with a reversing-switch *k* and a series-multiple switch *o*. In starting the car from rest the reversing-switch *i* is operated to direct the current through the motors in the proper direction, after which the arm of the series-multiple switch is moved to connect the motors *b* B in series, after which the motors are connected in multiple. The reversing-switch *k* is then operated to direct the current through the speed motors in the proper direction, after which the arm of the series-multiple switch *o* is operated, first to connect the speed motors in series and then in multiple, the starting motors *b* B being cut from the circuit after the speed motors have reached a predetermined speed.



TELEPHONE AND TELEGRAPH.

Telephones on Brooklyn Bridge.

Experiments have been made having in view the connection by telephone of the moving trains on the Brooklyn bridge with the train despatcher's office. The despatcher will sit in his office wearing a head telephone such as is used by the "Central" girl, and a long-distance transmitter will be at his desk. At the front and end of each train in service a telephone will be placed. In foggy weather the gripmen will wear a telephone receiver as a headpiece, so that they can respond instantly if called up by the despatcher.

The Underground Movement in St. Louis.

The agitation of the underground wire question goes on apace at St. Louis. The Association of Fire Underwriters of Missouri has condemned overhead wires of all kinds, and the members have agreed individually and as an association to do all in their power to secure municipal and State legislation looking to the burying of the wires.

Breach of Contract Claimed.

The Chicago "Inter-Ocean" states that a suit for $250,000 has been instituted in the Superior Court against the Cushman United Telephone Company. The plaintiffs are Sylvanus D. Cushman, inventor of the telephone of that name, and his wife, Idelia M. Cushman. The Cushman United Telephone Company was organized about a year ago with a capital stock of $20-000,000, which was entirely on paper. The company progressed so far as to rent an office, but the plaintiffs allege that the corporation never carried out any part of the contract which had been made with it. Under this contract Cushman gave up his patent rights and the company was to construct telephone lines and establish exchanges. The suit is for damages for the alleged breach of contract and to recover the property which Cushman surrendered.

A bill has been introduced in the House of Representatives authorizing the District Commissioners to permit the Home Telephone Company of Washington City to maintain and operate a telephone and telegraph plant in that city. The rates to be charged are not to exceed $30 for residences nor $42 per year for business houses, and the various Government departments of the District of Columbia and of the United States shall not be charged more then $18 per telephone per year.

The Citizens' Telephone Company has been organized at Florence, Ala. W. P. Campbell is president, M. B. Shelton, vice-president; James Burtwell, treasurer; H. B. Lee, secretary. The directors are: D. C. O'Steen, James K. Powers, Harry Smith and the officers above mentioned. J. W. Walker was elected superintendent of construction.

The York Telephone Company, York, Pa., has contracted with the American Electric Telephone Company, Kokomo, Ind., for an exchange equipment of 300 'phones.

The new branch telephone exchange in the "Hill" district of St. Paul, Minn, will not be opened until March, the postponement being caused by delay in completion of the switchboard.

The Municipal Signal Company of Boston has secured the contract for the police signal system to be installed at Albany, N. Y.

A project to connect Tifton and Sparks, Ga., by telephone by way of Staunton and Lenox is being considered.

At the sheriff's sale of the telephone plant at Independence, Kan., on the 18th ult., no bids were offered.

The new copper metallic circuit connecting Utica and Watertown, N. Y., has been completed.

The Postal Telegraph Company is making arrangements to extend its lines to Kingston, N. Y.

The directors of the Lansing Telephone Exchange, which is so successfully combating the Bell Company at Lansing, Mich., has elected officers as follows: President, Frank B. Johnson; vice-president, L. C. Blood; treasurer, Jacob Stahl. The selection of a secretary and manager will be made later.

An ordinance has been adopted by the city council of Newton, Kan., requiring A. R. Champlin to have his telephone plant in that place in operation by June 1 next.

The steamer "Faraday" is soon to sail from London with equipment and material for laying the cable up the Amazon river.

George W. Beers, W. J. Vesey, Charles S. Bash, Louis Fox and Charles McCulloch are interested in tho organization of an independent telephone company at Fort Wayne, Ind.

A company has been organized in Beeville, Tex., to construct a telephone system from Victoria to Tilden by way of Goliad, Beeville, Normanna, Pettus and Mineral City.

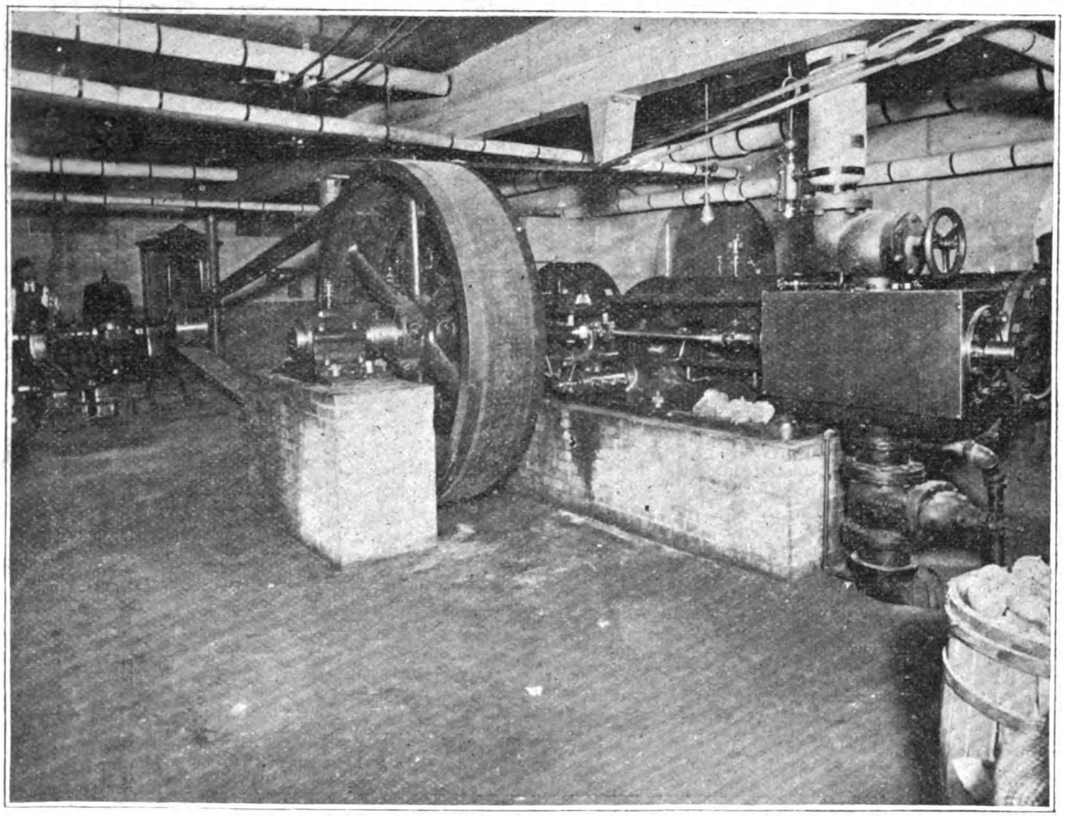
W. H. Harris, B. S. Harris and W. P. Harwell have incorporated the Fort Valley Telephone Company, Fort Valley, Ga., to construct a telephone system under franchise lately granted; capital stock, $5,000.

THE HOFFMAN HOUSE PLANT.

The accompanying illustration shows the arrangement of apparatus in the lately added engine room of the New Hoffman House, the electrical equipment of which was described in ELECTRICITY last week.

Prominently in the foreground is shown the High Speed Buckeye Engine connected by belting to the Fort Wayne Alternator. The switchboard is to the right of the generator, hidden from view by the band wheel of the engine.

The performance of both engine and dynamo has been entirely satisfactory. It is the intention of the management to practically duplicate this part of the equipment by the installation of another generator and engine of the same type.



WOOD ALTERNATOR-BUCKEYE ENGINE—HOFFMAN HOUSE PLANT.

COMMERCIAL PARAGRAPHS.

The Siemens & Halske Electric Company of America have opened new offices in the American Surety Building, 100 Broadway, New York. This will be the general Eastern office, and will be in charge of C. E. Yerkes, vice-president. F. N. Armour, recently of the Chicago office, will be the general sales agent. Chas. D. Shain still retains the agency for New York City and the immediate vicinity.

The Sunbeam Incandescent Lamp Company, Chicago, have recently commenced the manufacture of 2 C. P., 10 watt, and 4 C. P., 20 watt, incandescent lamps. These lamps have a small round bulb and are fitted with regular standard sockets. It is stated that the Sunbeam is the first lamp company to make lamps of such low candle power and wattage that they can be connected in multiple. The principal use for these lamps will be in sign and decorative work. In sign work especially a lamp of low candle power is preferable, even without considering the saving in energy, as with the glow of the small incandescent lamp the sign is clearer than with the glare of the larger lamp.

INCORPORATIONS.

The Weston General Company, Newark, N. J.—to develop electrical inventions and devices and manufacture and sell electrical machinery and appliances connected therewith. Capital stock, $200,000. Promoters: Edw. Weston, Newark, N. J.; Franz O. Matthiessen, New York City; Henry E. Niese, Jersey City, N. J.

The United Electric Light Company, Kansas City, Kan.—to operate works for the manufacture and supply of electricity for light, heat, mechanical and other purposes. Capital stock, $100,000. Promoters: C. F. Hutchings, Benj. Friedberg, Benj. Schnierle, Marcus Harris, Kansas City, Kan.

The Boston Electric Insulated Pole Company, Portland, Me.—to manufacture, deal in, and erect insulated poles. Capital stock, 100,000. Promoters: Edw. E. Drew, Boston, Mass.; Edwin L. Dyer, Geo. E. Macgowan, Portland.

The Oregon Electric Light & Power Company, Oregon, Ill.—to furnish light, heat and power. Capital stock, $50,000. Promoters: Albert H. Knodle, Wm. L. Taylor, H. Lee Allen.

The Ridley Park Light, Heat & Power Company, Ridley, Pa.—to supply light, heat and power or any of them by means of electricity. Capital stock, $1,000. Promoters: Richard S. Pomeroy, Chas. G. Darrach, Harry H. Sawyer, Ridley Park, Pa.

The J. E. Putnam Company, Rochester, N. Y.—to manufacture, construct and sell electrical appliances, apparatus, fixtures, specialties and machinery. Capital stock, $15,000. Promoters: Sylvanus E. Ellis, Jos. E. Putnam, Wm. B. Hale, Rochester, N. Y.

The Excelsior Electric Company, Port Huron, Mich.—to manufacture and operate arc and incandescent appliances. Capital stock, $120,000. Promoters: Henry McMarrao, W. F. Davidson, C. F. Harrington, Charles D. Thompson, F. G. McNutt, Port Huron.

The Lord Electric Company, Boston, Mass.—to manufacture, purchase and sell electric appliances and do all kinds of electric construction work. Capital stock, $15,000. Promoters: Fred W. Lord, Thos. B. Curtis, Nils Olson.

The Cleveland and Chagrin Falls Electric Railroad Company, Cleveland, O.—to construct, operate, etc., an electric railroad between Cleveland and Chagrin Falls, O., furnishing electric light, heat and power, etc. Capital stock, $300,000. Promoters: Vincent A. Taylor, F. W. Gehring, Jay E. Latimer, Jos. Black, Ferdinand H. Eggers, C. C. Barkwill, Albert V. Taylor.

The Bath & Lake Keuka Railway, Bath, N. Y.—to operate a surface electric railway ten miles long, from the Soldiers' Home, Bath, to the village of Hammondsport. Capital stock, $100,000. Directors: Israel A. Kelsey of West Haven, Conn.; John T. Prince of Boston, Mass.; John T. Prince, Jr., C. L. B. Tyler, F. H. Vielo, George E. Tyler, Chas. M. Hyde, E. J. Carpenter, and John L. Miller of Corning, N. Y.

Maguire & Backus, Ltd., New York City—to purchase and sell or otherwise dispose of patents, licenses, contract rights, powers, privileges, etc., relating to inventions, machines and processes, electrical or otherwise. Capital stock, $250,000. Directors: Wm. H. Paxton, Jr., Walter B. Howe, M. C. Fleming, Dr. H. Clark and A. E. Miller of New York.

The Rapid Transit Construction Company, Baltimore. Capital stock, $25,000. Incorporators: Wm. F. Rogers, Chas. H. Hopkins, Wm. O. Nelson, Harry C. Primrose and George N. Holloway.

The Wheeless Electric Lamp Company, Washington, D. C.—to buy and sell patents covering electric lamps, etc. Capital stock, $500,000. P. B. Thompson, of New York, is president of the company.

The Latrobe & Ligonier Electric Street Railway Company of Westmoreland County, Pa.—to build an electric railway twelve miles in length. President, Edward E. Robbins, of Greensburg, Pa.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 24, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

552,001. Underground-Current Supply for Electric Railways. August Rast, Nuremberg, Germany. Filed March 29, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

551,799. Electric-Arc Lamp. Elihu Thomson and Charles E. Harthan, Swampscott, Mass., assignors to the General Electric Company, of New York. Filed May 9, 1895.

552,036. Material for Incandescent Conductors. Ludwig K. Bohm, New York, N. Y. Filed Nov. 5, 1891.

DYNAMO ELECTRIC MACHINERY, ETC.

551,757. Electrically-Operated Elevator. Fred B. Corey, Boston, Mass. Filed May 13, 1895.

551,781. System of Electrical Distribution. Thomas F. Mullaney, Worcester, Mass., assignor to the General Electric Company, of New York. Filed Sept. 24, 1895.

551,809. Converting Simple into Polyphase Alternating Currents. Charles S. Bradley, Avon, N. Y. Filed June 11, 1892.

551,810. Alternating-Current Motor. Charles S. Bradley, Avon, N. Y. Filed Sept. 12, 1893.

551,820. Mechanism for Operating Elevator-Controlling Mechanism. Frank E. Herdman, Winnetka, Ill. Filed July 10, 1895.

551,856. Commutator-Brush. Caleb C. Dusenbury, Lake Mahopac, N. Y. Filed June 10, 1895.

551,868. Alternating-Current Machine. Maurice Hutin and Maurice Leblanc, Paris, France, assignors to the Societe Anonyme pour la Transmission de la Force par Electricite, same place. Filed May 1, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

551,947. Electric Telegraph. William H. Cooley, Brockport, N. Y. Filed March 23, 1889.

551,948. Electric Telegraph. William H. Cooley, Brockport, N. Y. Filed April 18, 1893.

MISCELLANEOUS.

551,785. Electric Brake. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed March 30, 1895.

551,786. Lightning-Arrester. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed Aug. 31, 1895.

551,790. Machine for Connecting Electric Conductors. Harlie J. Savory, Somerville, Mass. Filed April 17, 1893.

551,795. Electrogalvanic Belt. Samuel J. Spalding, Canton, Ohio. Filed May 9, 1895.

551,880. Electrical Eye-Cup. Theodore B. Wilcox, Newark, N. J., assignor to Eli Baldwin, New York, N. Y. Filed Jan. 10, 1895.

551,920. Electric Stop-Motion for Machines for Preparing Silver. William P. Canning, Lowell, Mass., assignor to the Lowell Machine Shop, same place. Filed June 19, 1895.

551,930. Electric Railway-Train Signaling. Walter S. Greene, Covington, Ky. Filed Sept. 3, 1895.

551,942. Electric Latch Apparatus for Semi-Automatic Operation of Railroad-Signals. Harry C. Barnes and William W. Slater, Oakland, Cal. Filed March 21, 1895.

551,982. Station Potential-Indicator. Ralph D. Mershon, Pittsburg, Pa. Filed April 29, 1895.

551,996. Pedo-Electric Trolley. Robert T. Oney, Charleston, W. Va. Filed March 27, 1895.

551,998. Electric Signal. Eugene M. Phelps and Archibald T. Sampson, Lynn, Mass., assignors, by mesne assignments, to the Farmer Electric Company, St. Louis, Mo. Filed Oct. 8, 1891.

552,053. Electrical Switch-Operating and Signal Apparatus. Justin Dutrey, New Orleans, La. Filed May 25, 1895.

552,057. Circuit Closer and Breaker. John R. Farmer, St. Louis, Mo., assignor to the Farmer Electric Company, same place. Filed Jan. 25, 1895.

ELECTRICITY.

Vol. IX. NEW YORK, JANUARY 8. 1896. No. 26

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

Publication Office, - - 6 Park Place, New York.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

Facts vs. Fancies. Extravagant claims of progress made, which cannot be supported or justified upon an impartial review of the actual facts, instead of being real helps to any science or industry, are calculated to check progress, hinder advancement and throw obstacles in the way of all earnest and honest workers. It is necessary to obtain and hold the support and confidence of those who can command the financial resources required to develop and perfect new departures, and anything that is calculated to alienate that support, or weaken its confidence in the justifiable claims and professions put forth in behalf of the new methods, is a check and hindrance to its legitimate progress.

No science or industry has suffered more from this cause than electricity. Wonderful and phenomenal as have been its progress and development in the last two decades, still more wonderful is the fact that it has been able to command the necessary financial support to make that progress possible, when we take into consideration the millions of dollars that have been contributed to foster impossible and chimerical schemes and lost. So many have lost money by trusting to the judgment of those in whom they thought they were justified in placing full confidence, only to find that confidence misplaced and their money gone, that there is now a wide and general feeling of distrust abroad, and it is of imperative importance that those who are looked upon as reputable authorities and guides should be particularly careful in not committing themselves to statements that cannot be thoroughly supported or substantiated. It is their place and duty to correct and do all in their power to check the wild and absurd claims, that are being made on all sides, of what is being done and is going to be done by means of electricity.

An article entitled "Progress of Electricity in 1895" and signed "Thomas Commerford Martin, Editor *Electrical Engineer*," that recently appeared in a newspaper of large circulation, contained some statements that it seems incredible should emanate from such a source.

While it cannot be disputed that great progress was made during the year just closed in various directions toward further utilization of electricity in the arts, sciences and industries, and a great deal was accomplished towards the perfection of apparatus, economy of operation, and also in the widening of its field of employment and usefulness, it has not reached any such stage of applicability to universal uses for power traction, heating, etc., that a perusal of Mr. Martin's paper would lead the public to believe, and in many departments never will until electrical energy can be generated in large quantities without the dynamo, and has not to be confined as at present to the transformation of power generated by other means.

It is not yet by any means certain that the Niagara power transmission scheme will justify the expectations and claims of its projectors and promoters on the lines now laid out and so far followed and proposed to be followed in the future. Indeed we are of the firm opinion that, with the immense outlay already made, and with the further immense outlay necessary to transmit the power to far distant points and there distribute it for general use as a substitute for steam power, there is little prospect of any return on the capital already invested and to be invested in the scheme.

We wish our readers distinctly to understand that we do not doubt, nor do we deny, the possibility of the transmission of electrical energy from the Niagara plant to even very great distances, but we do doubt, and do deny, that it can be done so as to be commercially profitable at points far distant from the place of generation as a complete and perfect substitute for steam power where coal is cheap.

It is the duty of a trade paper to do all it can for the best interests of the industry it claims to represent, and to foster its honest, stable and sound development; and it is equally the duty of every writer on the subject connected with the technical press of this industry to do likewise. Statements in the columns of the electrical journals of this country, tending to "boom" the industry on unsound lines, are sure to eventually injure the industry; and flowery and fanciful articles in the daily papers, written by persons connected with such journals, and tending to mislead the public concerning the possibilities of utilizing electrical energy, without reference to the commercial or practical results, are to be deprecated and looked upon as a direct and positive injury to the industry.

Power is only one of the items of cost in any industry, and in deciding upon a location for any factory all of them must be taken into consideration. In calculating the different items of cost in manufacturing industries, power is about 10 per cent. of the whole, taking an average. Raw material, labor and facilities for distribution are the guiding factors in the location of factories. It is generally cheaper to bring your source of power to your raw material than to transport your raw material to your power, other conditions being equal; and leaving out the important considerations of facility of distribution, etc., it follows that if the reverse had been the case we should find all the most important manufactories that utilize power situated in close proximity to the coal fields or water powers.

This matter of the feasibility of the profitable transmission and distribution of power to a distance by means of electricity has been much discussed during the past twenty years, and that by some writers who may fairly lay claim to being greater or less authorities on the matter. But notwithstanding the fact that Mr. Martin is one of the editors of the *Electrical Engineer*, it can scarcely be justly claimed that his training or experience has been such as to warrant anything that he may write or say upon this complex subject being accepted as authoritative or more than the product of the thought of a facile and rather versatile writer for the press, or as being anything more than a more or less complete reflection of the views of others.

The bane of electrical journalism in this country to-day is that the trade journals are mainly run or their policy is mainly directed by persons who are not trained electrical engineers, and whose main motive is to please their advertisers and thus secure advertising patronage ; and this is done without reference to whether such policy is for the best interests of the industry as a whole or not.

Much of the effusive writing on electrical subjects in other journals, which is now so prevalent, is due to the same spirit, and much of it emanates from the same class of writers as run or control the policy of the electrical trade journals.

We cannot in a short editorial discuss this matter of power transmission in the way it should be done ; but we caution all prospective or present investors in electrical power transmission schemes against accepting as authoritative on the subject the frequently much too flowery statements of writers identified with the regular trade journals, and also against overlooking the fact that their statements not only lack the weight of authority but may be more or less influenced by prospective profit.

It is quite common for such writers as are referred to to point to some particular instance of the successful transmission of power, under certain conditions most favorable to the use of this method, and then to reason that because in that particular case it is profitably done it can be done in all cases.

They seem to think that the price of such a commodity as power is fixed the world over, and that because electricity is sometimes economically and profitably used in the transmission of power it follows of necessity that if a system of power transmission is "electrical" it is not affected by the operation of ordinary business laws. With coal from eight to twenty dollars per ton, it is manifest that the commercial elements in the transmission of power must, of necessity, be very different from those cases in which coal costs from $1.25 to $3 per ton ; and no two cases of the transmission of power electrically can be fairly compared unless the conditions of the problem are stated, or are known to be exactly alike.

Power can be electrically transmitted from Niagara to Europe as easily as it can be delivered 100 feet away; but the question of what *can* be done is not the only factor to be considered; it is, as before said, a matter of dollars and cents, and we believe power cannot be electrically delivered from Niagara to Buffalo as cheaply as it can be produced locally by steam power generated and used under proper conditions.

In electric traction for street railways and suburban or rapid transit work, where light trains and frequent service prevail, there is no room to doubt as to the economy of the electrical method of operation, for power can probably be more economically subdivided into small units by that system than by any other, but to maintain that electricity can be substituted for steam locomotion in all the conditions of service is both misleading and ridiculous, and anyone who understands sufficient about the subject to figure out the cost of electrically equipping and operating a main line of railway for, say, 300 miles, will soon abandon any idea of relegating the steam locomotive to the scrap heap.

Again, Mr. Martin says : "Prominent also in the annals of 1895 is the application of electricity to the Erie Canal in a *successful and scientific way.*"

That canal boats *can* be electrically propelled is without doubt true. The fact that one was so operated is doubtless also true, but to say that it was done in a "*successful and scientific way*" is putting our credulity to too great a strain, for anything more unscientific, unmechanical and uneconomical it is difficult to conceive; and to ask us to believe that they will shortly be running canal "greyhounds" by this system is little less than an insult to the understanding.

Now, coming to the problem of electric heating—in spite of Mr. Martin's assertion that it made a mighty stride forward in 1895, it made no stride whatever, and never will as long as the electrical energy is produced as now by the transformation from coal to heat in the furnace, water to steam in the boiler, steam to mechanical energy in the engine, mechanical to electrical energy in the dynamo and then transmitted a distance to the electric heater to be finally transformed into heat. Under the most perfect conditions not more than 10 per cent. of the heat generated by the combustion of coal is available for distribution by the electric heater, and in most instances it would not be more than half of that.

Electric heating is available now, as it has been heretofore, to everyone to whom cost is a matter of indifference, but it is about equal in economy to coal at $50 per ton. The fact that some of the trolley roads have been installing electric heaters (the same that have been on the market some years) is no justification for the statement that electric heating has "made a 'mighty stride' in 1895."

The Brooklyn road which Mr. Martin alludes to put heaters in their 500 cars. These heaters each absorbed the first cold day about 12 amperes per car to perceptibly warm them ; that at 500 volts pressure was about 8 H. P. per car, or 4,000 H. P. for the whole. It was almost a question which the company should do, warm the passengers or take them to their destination, for it seemed at one time impossible to do both with the power at their command.

It is feared that the "influential capital" that is being invested in the exploitation of such heaters will not yield a very heavy dividend for its subscribers.

The electrical industry has had a long and hard struggle, but it has so far survived the attacks of its most open and adverse opponents whose domain it has curtailed. In its future advance, as in the past, it has less to fear from its avowed enemies than from its supposed friends. Its principal danger is within its own ranks—fraudulent financiers, plausible but dishonest schemers, and last, but not least, injudicious and meretricious writers for the daily and technical press and the strictly trade journals.

Let all honestly engaged in the industry frown down the constant and apparently ever-increasing stream of articles tending to mislead the public concerning the possibilities of the application of electricity in the various arts and industries in which it is employed, no matter from what source the articles may emanate.

* * *

Why European Lamps Are Poor.

The somewhat acrimonious discussion of incandescent lamp tests, which recently appeared in the English electrical press, has done much to confirm the belief held by most American electricians that European lamp makers have sought more to produce a lamp of low first cost than one possessing the more important qualities of high efficiency and sustained candle power. Following the publication in Electricity of the tests of European lamps made by Mr. D. Paisley, a number of English manufacturers have rushed into print with declarations tending to substantiate rather than to controvert the correctness of the results established by these tests. These communications have in the main been confined to a discussion of the relative merits of the several lamps tested, and have merely been protests from the manufacturers whose lamps, on actual test, have failed to sustain the claims made for them. However vehement these critics may have been, and notwithstanding the original tests were published in journals which our abstruse and extra dry contemporary, the London *Electrical Review*, pleases to regard as "not strictly technical," the fact remains that the conclusions reached by Mr. Paisley have not been proven to be incorrect. The exceptions taken are such as would be expected from interested manufacturers, and even if the ratings given the lamps in the test are different from those claimed by the manufacturers, no data has yet been published which will show a higher efficiency or greater sustained candle power of European lamps than was given in the original tests.

This controversy has brought into prominent notice a number of interesting facts in connection with the manufacture of lamps in Europe. It is plainly evident that, among English makers at least, there is not that refinement in factory practice, or the care in the selection and preparation of materials, or the careful testing of finished products, such as may be found in any well-regulated American factory. But little attention appears to be paid to the candle power rating of lamps, and even less to standardizing. The aim of most manufacturers seems to be to produce lamps that can be sold at the lowest prices—"not merely," says *Electrical Plant* "because they avoid payment of heavy royalties for patents, but because they lessen the cost of production by devoting insufficient attention to standardizing."

That the product of the Continental lamp makers has been quite as defective as that of their English competitors is shown by the report of a commission appointed by the Union Representatives of Electricity Works to investigate the incandescent lamp question in Germany. The report, published last week in Electricity, states that "the complaints of consumers that the lamps are bad—good for nothing—are justified."

The committee found these complaints to be based upon the following causes : "Imperfect sorting, false marking, little economy and too short life of the lamps." In 70 lamps supplied by eight makers, which were given as 16 standard candle-power, and whose rate of consumption should have been 3.25-3.50 watts per candle-power, the illuminating power fluctuated between 7.82 C. P. and 22.85 C. P. and the rate of consumption between 2.8 and 6.3 watts per candle-power.

It is a source of some congratulation to know that, with few exceptions, American lamp manufacturers have profited by the experience which followed a sacrifice of quality to price. Their European brethren seem slow to learn in the same school, but until they do there will be no improvement in either the quality or price of their product.

* * *

Our London namesake has an honest correspondent who admits that "we Britishers are sadly behind even some of our colonies in electric lighting and telephony—especially the latter. One has only to travel abroad a bit to realize the many ways in which Great Britain is behind the world."

* * *

In France the price of Welsbach burners has been reduced to $3.20, in Germany to $1.25. *The Progressive Age* explains that the ground for this action is said to be in that the incandescent gas light companies of those countries have enjoyed a phenomenal business and have practically secured all the business that could be had at fancy figures, and the reduction in price has been made in the nature of a bid for trade among the poorer classes who have been deterred from introducing Welsbachs because of the prohibitive first cost.

* * *

It is stated that the Chilian Government has decided to establish an electrical section mainly with the object of familiarizing naval engineers with the principles of electrical engineering

Under the Searchlight.

Views and Opinions on Timely Topics.

To Offset the Bell Lobby.

To the Editor of ELECTRICITY.

SIR: Referring to the item in your issue of some weeks ago regarding the action of the Attorney General in asking the advice of Congress in regard to the prosecution of the Berliner case—while occasion for this action on part of the Attorney-General may exist, it strikes me that it offers an opportunity for the Bell people to get in some dangerous lobbying, which might defeat a necessary appropriation, and in other ways discourage the proper conduct of the case.

From "straws" which I have observed, I believe that the Bell people are afraid to have the case come to trial, and our company at least will bring every possible pressure to bear with our Congressmen to favor a large appropriation and have the case handled to the best possible advantage. Being aware of your friendly feeling toward *legitimate* independent telephone interests, I make bold to ask if you will not call attention to this matter in your next issue (providing, of course, that you consider it good policy), requesting every man who is in any way interested in the success of the independent telephone movement to have all possible pressure brought to bear with the Representative from his district to favor the prosecution of the case.

I fully agree with the opinion which you expressed in an issue several weeks ago, to the effect that it is better for the independent people to assist the Government in this case than to ignore it, for several reasons. Yours truly,

Boone, Ia. W. E.

Where is Burton?

A few weeks ago, it will be remembered, the *Electrical Engineer* gave a page or more to a description by George D. Burton of a process, of his invention, for the electrical smelting of ores. ELECTRICITY at once pronounced the invention, the system and the company to be nothing less than gross frauds, and chided our contemporary for allowing such matter to appear in its columns. A few days later Mr. Burton called at this office and offered to make a practical demonstration of his discovery. We offered him every facility, including current and power. He never came back. Later we were advised by one of his agents that there was to be a public exhibition at the works of the Eddy Company at Windsor, Conn., and that a quantity of ore had been shipped there. The exhibition has not been held, and Mr. Burton has been advised that the generator built for him awaits shipment upon receipt of check for same in advance. When in Chicago recently, a representative of ELECTRICITY met some of the California gentlemen to whom Burton had sold "rights" for that territory. They were gunning for Mr. Burton, who had fled the city or changed his hotel.

We trust our contemporary is properly proud of the assistance it gave to this fraudulent scheme.

* * *

These are the times which try men's souls, especially the souls of G. E. managers. When stocks once quoted at 120 are oscillating between 20 and 25 things look blue. But still worse is in store for our friends the enemy.

* * *

IF Diogenes lived in this progressive age he might even yet be unable to accomplish the object of his historic search, but he would certainly be better equipped with apparatus to aid his failing powers of vision. An inventor has recently secured a patent for a contrivance to be used either as a cane or electric lamp, to carry which, in Athens, or even in New York, would attract less attention than would the early form of searchlight employed by the discerning philosopher. This article is described as follows:

It is hollow, and the interior is filled nearly to the top with the necessary chemical solution. The knob is really an incandescent bulb, with an ornamental and protective covering of nickel or silver, which either unscrews or flies open at a touch upon a spring. The poles of the battery extend into the hollow of the cane, but not far enough to reach to the acid. But when a light is desired the cane is held knob downward, the acid attacks the zincs, and the electricity generated lights the bulb. They give out a really surprising amount of light and last nearly two hours. There is no waste of material when the light is not in use, as no electricity is generated except when the cane is turned upside down and the acid so brought in contact with the zincs. So a single filling may last for weeks or months. When the bulb is burned out, or the zincs are eaten away, or the acid loses its strength, the owner can easily reload the cane, as the supplies can be bought for a trifle.

The Reason For It.

(With apologies to Frank L. Stanton.)

The world is always sunny
To the man who spends his money,
But you've got to hunt the honey
Like the bees.
If they stayed inside the hive—
Didn't show that they're alive—
Would their honey-making thrive
By their ease?

Though little trade is goin'
There is still some money flowin'
To your rival who's been sowin'
Left and right.
So you've got to ope your eyes,
You must learn to advertise,
Or you'll never win the prize
In the fight.

THE NEW TESLA RAILWAY MOTOR.

A gentleman, described by the St. Louis *Globe-Democrat* as "one of the shrewdest electrical engineers in the employ of the Westinghouse Electric and Manufacturing Company," was recently interviewed by a reporter of that paper, to whom the following statements were made in reference to the Westinghouse-Baldwin combination, and the new railway motor now being perfected by Nikola Tesla:

The Westinghouse and Baldwin companies have become convinced that the demand for electric locomotives will grow rapidly in the near future. The steam locomotive which the Baldwin company has been making for sixty years is not to be laid on the shelf right away, but that company has come to believe, I think, that it will gradually, but surely, be displaced by its electric successor, and has grasped the opportunity to take advantage of the coming change by joining forces with one of the two great electric manufacturing companies which control the supply of such motors in the United States.

The allied companies propose to perfect and to offer to the steam railroads electric locomotives which they will buy and use. The resources of both concerns; the electric inventions, devices and experts of the one; the methods, the expert locomotive and running gear machinists of the other, are being taxed in the effort to produce a motor which the steam companies can use to advantage for any kind of service, but especially for the rapid and safe transportation of passenger trains running more frequently than the steam trains at the present time.

The demand first to be satisfied is for electric locomotives to draw passenger trains on the suburban roads of the trunk lines. The demand already exists—in fact, all the Eastern steam companies have placed large orders.

Tesla is working on an idea in the shape of a motor that I believe will about successfully equip a locomotive with the power desired. This motor is entirely original and truly marvelous. The secret lies in turning the inert and seemingly lifeless force of magnetism into an active force more powerful than steam or a current from a dynamo.

The principles of the motor, concisely put, are these: An electric current is passed through a circular magnet, in appearance resembling a life-preserver. It consists simply of a ring of iron with copper wire bound around it. The electric current generates a strong magnetic current which flashes around and around the circular magnet at terrific speed. Now, if one holds a nail close to an ordinary electric magnet it will be passive in the hand until it is brought close enough for the magnetic force to seize it, when it will fly out of the hand straight to the magnet. But if one holds a nail close to the circular magnet of Tesla it will begin to revolve in the hand; that is, if the nail is held by the head and the point allowed to hang over the hollow center of the magnet, the point will move around in a circle, slowly at first, then faster and faster, until, if it is dropped upon the table in the center of the hollow it will spin around so rapidly that the eye can not follow its motions.

Several explanations are given of the phenomenon one that there are several magnetic currents in the iron ring and they are chasing one another around in a furious race, but the mystery is as profound as ever.

Another interesting experiment is the balancing of an iron wheel on a nail, or let the wheel revolve upon the finger, using the finger as the axle, and holding it close to the magnet. It will fly around at a rate that will take one's breath away. It is not necessary to touch the magnet at all. All one needs to do is to hold a piece of iron or steel in the hand and bring it within a foot of the magnet, and then he will feel a queer sensation, as of some invisible force trying to draw the piece of metal out of his hand, and, failing in this, trying to twist it around in a circle.

Such is the principle of the coming Tesla motor. In its application as a motive power on the railroad, the construction, of course, differs from that of the experimental magnet, but the idea is the same.

In equipping the new locomotives the circular magnet is attached to the bottom of the engine, and the axle upon which the wheels revolve passes through the center of the magnet without touching it. When the current is turned on, the magnetic force whirling around in the hollow of the magnet catches the axle and turns it. The power for generating this magnetic current can be transmitted by underground wires for almost any distance, and there is practically no waste of power or energy.

We think the time has arrived when we may, with perfect justice and propriety, clearly indicate the policy of this paper in relation to press notices of a character similar to that printed above.

We should like to know—

1st. Is the Westinghouse Company responsible for the statements in that article, or does it encourage its press agent to give public currency to such statements?

2d. If it does, what is the object of such statements?

3d. Who is the person referred to as "one of the shrewdest electrical engineers in the employ of the Westinghouse Company?"

We ask these questions because we should like to definitely fix the responsibility for the many obviously untruthful statements made in the article.

Can it be truthfully stated that either or both of the two great electrical manufacturing companies in this country control the supply of electric locomotives employing either direct or alternating currents? We think not. Indeed we know that this field of work is fully open to any one who wishes to enter it, or any who are already engaged in it.

We know that Mr. Tesla is not engaged on electric locomotive work, and the description of the motor given in the article and its principles of operation differ in no way from the well-known rotary field motor used for years past in this country and Europe.

Is it not about time that the large electrical manufacturing companies of this country stopped this kind of puffery and misstatement of facts? Such notices certainly do not materially strengthen the position of the company responsible for them in the eyes of the general public, nor increase the confidence of capitalists in electrical enterprises.

Any sensible business man knows if any company engaged in any line of business has a startlingly novel and useful invention, of such a revolutionary character as is supposed to be described in the above article, that it is most unwise to publicly announce the fact before the invention is ready for the market, such a course of action being invariably followed by its competitors exerting unusual diligence to find out what the new thing is, and stimulating them to make the utmost exertions not to be left behind in the race. An article of the kind referred to may indeed be looked upon as public notice to its competitors of the direction in which the company making the announcement is working—a thing which everyone possessing a modicum of common sense desires to avoid and carefully endeavors to conceal.

The public have already had enough of promises of what is going to be done and too little fulfilment of such promises.

PROFESSOR FORBES ON "HARNESSING NIAGARA."*

BY ERNEST A. LE SUEUR, SC. B.

The past few months have seen the successful completion of a gigantic work, of epoch-making extent and significance—the Niagara Falls electrical power transmission plant. An article appeared in these pages in September, 1894, describing something of the difficulties which had been met and overcome by the engineers in charge of the water power and generator installation of the Cataract Construction Company, as the corporation which had the contracts for erecting the plant was named.

Prof. George Forbes, who held the position of consulting electrical engineer to that company, is to be heartily congratulated upon the success that has crowned his efforts. It becomes pertinent at present to insist, however, that Prof. Forbes should be content to limit his claims to glory to the considerable work that he has undoubtedly accomplished, for, unfortunately, he appears not overanxious to define that limit when discoursing to the public about his achievements.

There has been some bickering between Prof. Forbes and Prof. Rowland, of Johns Hopkins, as to which of the two was the originator of certain of the novel points in the Niagara Falls Power Company's generators. The atmosphere is very murky in consequence, but some facts would seem to have filtered through, and we shall take occasion to refer to them later. What seems to call for notice at this moment is a paper by Prof. Forbes, which appeared in the September "Blackwood's," entitled "Harnessing Niagara."

It is doubtful if any American magazine would have published that article, even had it contained fewer references to the shortcomings of the United States. It seems to us, however, that it would have been much better for it to have appeared in this country than in Great Britain, because of the freer criticism it would here have had, and because America's faults would then have been told where it might be hoped that, coming from so authoritative a source, certain valuable reforms would result.

A large portion of the article is devoted to a description of Forbes's own unusual endowments and capabilities, natural and acquired, which, it would appear, fitted him for the position of consulting electrical engineer to the Cataract Construction Company, not less than for the suppression of the American railway conductor. A perusal of the article brings to one's mind the couplet by a famous English librettist:

> "He was the bravest man in France;
> He said so and he ought to know."

Turning to such portions of the paper as do actually bear upon the Niagara work, we have, as above mentioned, the professor's remarkable claim to originality in the matter of the revolving fields. Again, in describing the steps leading to his choice of apparatus, he says: "I soon realized the fact that not only could the latter (alternating) current be more easily obtained at high pressures, but that it could more easily, and without moving machinery, be transformed to any required pressure at any spot when it was wanted." This statement, it is to be regretted, is nothing short of dishonest. Forbes is here speaking of the year 1890, at which date the fact that he refers to as having worked out for himself was literally the A B C of electrical work and part of the common knowledge of thousands of "line" laborers throughout the world.

With regard to the two points so far mentioned the distinguished engineer has not sought to belittle the work of others, but only to magnify his own; he has not, however, confined himself to this more moderate course, and we find him stating that "the highest scientific authority in America had taken up the same position as Lord Kelvin," referring to the latter's alleged strenuous opposition to the use of the alternating current. The eminent authority referred to would seem to be Prof. Rowland, of Baltimore. This gentleman, who ought to know what it was he advised, states positively that he did not strenuously oppose the use of the alternating current; that he did not oppose it at all; and that, moreover, his opinion was given in 1889, not 1890; that what he did advise at that early date, in view of the untried state of either direct or alternating current transmission, was merely caution in adopting plans; which advice, we may add, was most carefully followed, as will be seen from the fact that the main plans, not to speak of the details, were not decided upon until three years later, during which interval some most remarkable developments had taken place both in the design of machinery for use with alternating current and in the practical transmission of the latter over an immense distance in Europe.

Our writer says: "Until I went to America the manufacturers of electrical machinery never had a consulting engineer to reckon with, but dealt directly with the financiers, who knew nothing about cost or efficiency of machinery," and reference is later made to his being the first to get guarantees of performance from manufacturers of such machinery. The present writer speaks from personal experience in declaring this to be incorrect. The way in which a company, larger and even more representative than the chief one with which Prof. Forbes did business, filled an 1,100 horse-power contract under guarantee, and later supplied an auxiliary generator to make the guarantee good, would perhaps have impressed that gentleman. The particular occurrence referred to is immediately within the writer's knowledge, and the extremely exacting specifications for the said machinery were written and insisted upon by consulting engineers and not by the financiers. It should, however, be unnecessary to say that, of course, the method of requiring guarantees and of employing engineers to write specifications was common in the electrical business, as well as in all others, long before the advent of Forbes.

There are other points in the professor's paper besides those already referred to which require contradiction, and still others, covered by the matter in controversy between himself and Prof. Rowland, which there is every reason to believe might be improved in the matter of accuracy, but which, since directly opposite statements are put forth by the two men, we must be content to let stand in default of other sources of information regarding them.

An opinion of Prof. Forbes that surprises us is set forth in the sentence, "I had always wished to put the dynamos at the bottom of the pit close to the turbines, and I still believe that this arrangement would have served us better." It is the opinion of the writer that it is an unusually good thing for the Niagara Falls Power Company that the above was not done. In his experience it is a practical impossibility to keep penstocks under great head from leaking, and the moisture thereby communicated to the atmosphere, as well as that due to the location of the dynamo room at the bottom of a narrow pit 150 feet deep, with a torrent carrying a hundred million gallons per hour raging immediately beneath, could not well fail to impair the machines' insulation. Since the latter must carry a vast electrical pressure of alternating current, any impairment would be fatal to the maintenance of the plant. An instance occurs to mind in which a generator plant was located on a level with the wheel cases, and this not at the bottom of the pit by any means, but at the top of a draught tube some feet above the level of the surrounding ground, and in which, owing to the moisture unavoidably present, the generators had subsequently to be removed.

In an opening paragraph Prof. Forbes speaks of the production of the paper under discussion as the result of an attempt to curb a natural tendency to reticence, and, later, in describing the Falls of Niagara, he says "the most impressive points of view are those that make you feel the smallest." It is not apparent whether the professor himself experienced the sensation, but if he did the depression must have been evanescent, for near the end he says that, while his company ascribes his "splendid results" mainly to engineering skill, "I am inclined to believe that they were fully as much the result of an exercise of tact, judgment and forbearance, combined with firmness—qualities which I do not hesitate to say that both the officers of the company and myself recognized in each other." All of which, while possibly true, is scarcely the utterance of a man hampered by a temperament in which reticence and a feeling of insignificance are struggling with each other for supremacy.

Americans have faults and are not more sensitive to having them pointed out than other people, but the tendency among descendants of Anglo-Saxon stock to resent the imputation of the possession of visual motes by ill-tempered owners of larger ocular imperfections is deeply rooted. We have not for many a long day seen an article in a prominent English journal so well designed, by its gratuitous disparagements of America, to keep alive the fast-expiring dislike to the mother country that it is to the interest of all of us to see buried.

---

* From the "Popular Science Monthly" for December.

AN INVESTIGATION OF THE ALTERNATING-CURRENT ARC.*

BY J. A. FLEMING, D.SC., F.R.S., AND J. E. PETAVEL.

During the last six months investigations have been carried on by us in the electrical laboratory of University College, London, with the assistance of some of the senior students, which form part of an analytical study of the alternating current arc as yet not quite complete. Two arc lamps were selected of well-known types—one of them suitable for working with continuous current and the other with alternating current, the lamps being chosen with a view to good regulation and steady working over wide limits of power consumption.

The first portion of the experimental work consisted in the construction of an inspectional reflecting wattmeter, intended to enable the observers to measure and to regulate with great accuracy the power taken up in the arc itself, neglecting altogether the power absorbed in the mechanism of the arc lamp. The wattmeter consisted of a fixed coil, which was the current coil of the instrument, and through which the current of the arc passed, and a movable coil hung by a bifilar suspension, the two suspending wires being exceedingly fine silver wires. In series with the suspended coil was a non-inductive resistance, capable of being varied in magnitude within certain limits. The suspended coil had affixed to it a plane mirror, and an image of a wire illuminated by an auxiliary arc lamp was thrown by it on to a fixed scale. The suspended coil consisted of 33 turns of wire, and the fixed coil of 10 turns of thicker wire. The non-inductive resistance, in series with the suspended coil, had a resistance of 1,200 ohms, the resistance of the shunt coil of the wattmeter being 3.67 ohms and that of the fixed coil 0.01 ohm. The wattmeter was fixed firmly to a wall, and the scale carried at a fixed distance opposite to it. The wattmeter was calibrated by means of continuous currents, and by means of an interpellation curve the power, reckoned in watts, passing through the wattmeter could be read off from the position of the image of the wire thrown upon the fixed scale. The terminals of the fine wire coil were connected to the arc carbons. In all the experiments the wattmeter readings were subsequently reduced so as to give the true power taken up in the arc, neglecting the power required to actuate the arc lamp mechanism and the power taken up in the voltmeter and wattmeter itself.

In addition to the wattmeter measurements, the current through the arc, as well as the potential difference between the carbons, was taken by properly corrected instruments, and the length of the arc was also measured at the same time by projecting its image upon a screen. The photometric measurements were made with Sugg's star disk photometer, the *light* from the arc lamp being compared by this means with that of an incandescent lamp, which was worked at a sufficient voltage to bring it up to about 2½ watts per candle, the incandescent lamp being compared at frequent intervals with a primary standard incandescent lamp.

---

*Abstracted from *The Electrician* (London).

It was found that by focussing the eye for a point rather nearer to the eye than the images of the photometric disk the color difference between the two images became less distracting, and in this manner the observations that were made are all taken in terms of a white-light standard, no measurements made in terms of red or green light having any practical value. The experiments consisted in taking a series of observations of the photometric intensity of the arc in different angular directions to the horizontal plane through the arc in the usual manner, the power supplied to the arc being kept perfectly constant by a regulating carbon resistance in series with the arc. A complete series of observations was taken with the continuous current arc when supplied with power of from 200 to 600 watts. For each complete set of observations the wattage in the arc was kept perfectly constant, and from the photometric observations the ordinary illumination curve of the arc could be plotted out, and the mean spherical candle-power calculated in the usual way by means of Rousseau's diagram. In the case of the alternating-current arc, owing to the circumstance that there is a slow periodic rotation or change of place of the arc, quite independent of the fact that the current or the wattage in the arc is maintained perfectly constant, the photometric measurements become particularly troublesome. In this case it was necessary to take a series of photometric observations rapidly in different azimuths for each particular inclination angle, and to take the mean of these observations. Carrying out this process, a series of illumination curves was obtained for the continuous and the alternating-current arc, which had the usual characteristic form. In both cases these experiments and measurements of the mean spherical candle-power were repeated for different expenditures of power in the arc varying from 200 to 600 watts. The alternating current experiments were made at two frequencies—viz., 50 ∼ and 83.3 ∼. The carbons used in the case of the alternating-current experiments were both 15 mm. cored carbons of the best quality, and in the case of the continuous-current arc experiments two sets of observations were made, one with both carbons cored and 15 mm. in diameter, the other set with the positive or upper carbon cored and 15 mm. in diameter, and the lower or negative carbon solid and 9 mm. in diameter. When all the necessary reductions of the hundreds of observations were made by the integration of the illumination curves to give the mean spherical candle power, and the reduction of the wattmeter scale readings to give the true power in watts expended in the arc itself, apart from anything taken up in the mechanism or instruments, the results were embodied in a series of curves as shown in Fig. 1, in which the horizontal distances represent the power in watts taken up in the arc, and the vertical ordinates the mean spherical candle-power. The four curves there shown show the variation of mean spherical candle-power for the particular carbons used for the various powers employed in the case of both arcs, the details of the observations being given in the table above.

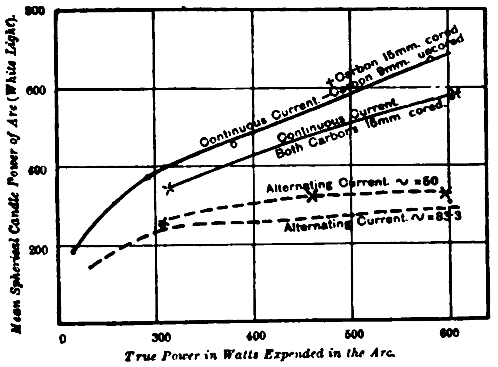

FIG. 1.

The general result of the above-described experiments therefore confirms the conclusions reached by one of us in 1894, and which indicated that for a given amount of power expended in the arc under the conditions under which these experiments were carried out, the mean spherical candle-power for continuous current was nearly double that for the alternating current.

—	Continuous-current arc.					
	+ Carbon 15mm. cored. — Carbon 9mm. solid.				Both carbons 15mm. cored.	
Power expended in the arc in watts	582	380	292	215	607	313
Mean spherical candle-power	675	455	372	181	582	344
Potential difference of carbons in volts	56	44	36	26	60	40
Current through arc in amperes	10.6	8.7	8.1	8.2	10 2	8
Length of arc in centimeters	0.715	0.25	0.07	0	0.807	0.061
Power factor	1.0	1.0	1.0	1.0	1.0	1.0

—	Alternating-current arc. Both carbons 15mm. cored.							
	Frequency 83.3 ∼					Frequency 50 ∼		
Power expended in the arc in watts	601	501	404	305	233	596	459	308
Mean spherical candle-power	307	274	256	250	144	326	322	254
Potential difference of carbons in volts	37.5	34	28	21	15.8	39	31	22
Current through arc in amperes	16.2	15.1	15.1	15.5	15.4	16	15.1	14.6
Length of arc in centimeters	0.628	.....	0.125	0.016	0.01	0.7	.	.....
Power factor	.....	.....	0.96	0.96	0.99	0.97	0.99	9.97

In reading the above tables it must be noted that it was the power, measured in watts, taken up in the arc which was kept constant. The current and difference of potential of the carbons were allowed to take care of themselves. The current and volts were approximately constant, and had the mean values given in the tables, but the product of these mean values does not quite agree with the true mean power measured in watts taken up in the arc.

The above-described experiments do not, of course, by any means exhaust the subject. The question whether continuous-current arcs *per se* are more efficient than alternating-current arcs in regard to mean spherical candle-power produced per watt is a large question to consider, and perhaps cannot be answered in a general sense, but it is capable of being settled for any particular instances which occur in practice. It is for this reason that we selected the two typical cases of an alternating-current arc worked with 15 mm. cored carbons worked at frequencies 83.3 ∼ and 50 ∼, and compared it with a continuous-current arc worked with 15 mm. and 9 mm. carbons as commonly employed. The experiments, of course, do not settle whether any particular form of alternating-current arc can be produced which shall give the same mean spherical candle-power for a given expenditure of power as a continuous current arc with the same carbons, and such a question has, perhaps, too purely an academic interest to make it worth while to spend time upon it.

These experiments amply justify generally the opinion which has been held as to the relative inefficiency of alternating-current arcs in mean spherical candle-power, apart from any question as to differences in the distribution of the light, and show the correctness of the opinion which dictates the employment of continuous current or rectified alternating current for public arc lighting purposes.

The second part of the investigation was concerned with an analytical examination of the periodic variation of light coming from various parts of an alternating-current arc. For this purpose an alternating-current arc was formed with currents of frequencies of about 83 ∼, 50 ∼, and 25 ∼.

Fig. 2 shows a complete set of observations giving the current through the arc, the potential difference between the carbons, the power expended in the arc, and the variation of the light in the center of the true a c, excluding any light coming from the incandescent carbons. The firm line curve in Fig. 2 therefore represents, by its ordinates, the periodic variation of the light coming from the purple arc discharge lying in between the carbons, but does not include any light coming from the carbons themselves.

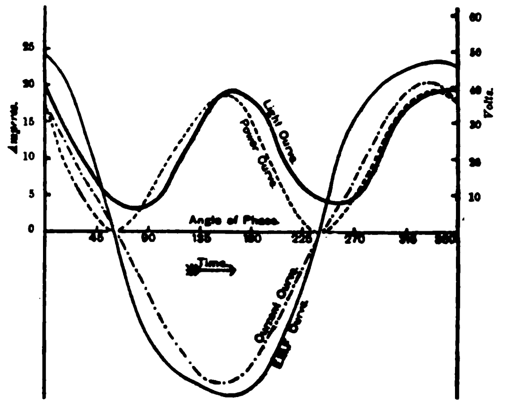

FIG. 2.

The ordinates of the firm line marked "Light" represent the periodic variation of illuminating power of the center of the *true arc* of an alternating-current arc. The other curves marked E. M. F., current and power represent the variation of potential difference of the carbons, current and power in the arc. Carbons, 15mm. cored; ∼ = 83.3; amperes = 14; volts = 39; length of arc, 0.55cm.; volts at alternator terminals = 104.

It was found that the blue or purple light forming the true arc in between the carbons undergoes a periodic variation in intensity, completely vanishing at a certain instant during the phase, but at the same time there is outside this true arc a dim halo of golden light which is persistent, and it is on account of this persistent aureole of faint light that the ordinates of the firm line curve in Fig. 2, which represent the variation of light in the true arc, never becomes zero, but there is always an outstanding constant amount of light. In order to select as far as possible merely the blue or purple colored light from the true arc, irrespective of any admixture of white light coming from the aureole, a blue gelatine transparent screen was employed to select a certain group of rays. By shifting the position of the mirrors slightly it was possible to measure the periodic variation of light coming from any part of the incandescent carbons. The diagram in Fig. 3 represents the periodic variation of light coming from the center of the crater of the lower carbon, the other curves of the same diagram representing the variation of current through the arc, potential difference between the

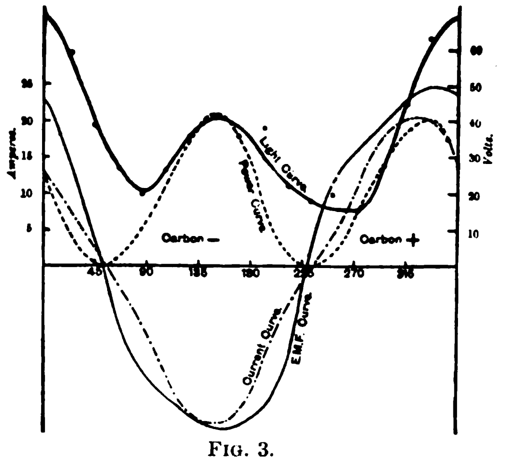

FIG. 3.

The firm line curve in the above diagram represents the variation in illuminating power of the *crater* of the lower carbon during one complete phase of an alternating-current arc. Carbons, 15mm. cored; ∼ = 83.3; amperes = 14; volts = 36; length of arc, 0.42cm.; volts at alternator terminals = 98.

carbons, and power expended in the arc. It must be noted that the scale to which the light curve in Fig. 3 is drawn is very different from that of the light curve in Fig. 2, as the crater is, of course, far more brilliant than the true arc. The interesting point to notice is that during the time when the lower carbon is negative the maximum light emitted from the center of the crater of the lower carbon does not reach such a maximum value as it does when the same carbon is positive. For a frequency of 83 it is not much more than one-half as great—that is to say, the brilliancy of the crater on the carbon undergoes a periodic variation, but at the instant when the carbon is negative and when the maximum power is being expended in the arc the brilliancy of that part of the carbon is not much more than one-half that which it is when the same carbon is positive and receiving its maximum power expenditure. The lower the frequency, the greater this difference. It is easy to distinguish the part of the period during which the lower carbon is negative from that in which it is positive by holding a magnet at the back of the arc and noting which way it causes the image of the arc to be deflected.

It is evident from the curves in Fig. 3 that there is a certain lag in the curve representing the variation of light from the carbons behind the curve representing the power; in other words, the light lingers on a little after the power has fallen to zero. It will also be noticed there is a very slight difference of phase between the current and the electromotive force, which is also found in all the other curves taken with the alternating current arc.

Gas Engines and American Incapacity.

(From the Scientific Machinist.)

There is not perhaps a larger market for any mechanical device of which a need is felt than for a small gas and gasoline engine. The mechanic who will build a one H. P. fairly efficient gas engine and sell it at about the cost of a one H. P. steam engine will secure a trade of very large proportions. If he should be able to realize a fair profit on each sale—and otherwise it would be dangerous to engage in that or any business—a large fortune could undoubtedly be built up in a few years.

The question is often asked, why are Americans, who in most matters of enterprise generally have no superiors, so backward in the use of gas and gasoline engines. And it is a pertinent question which no one can answer. The English lead us in this line of work, and perhaps this only. They adopt our steam engine and boiler designs, machine tool designs and have modified much of their engineering work in various branches along the line of American ideas, but they are our masters in the design of gas engines. Not only this, but our manufacturers are either so egotistical or fossilized that they see nothing of the kind, admit no part of the truth, and apparently care nothing about doing their plain duty by their customers and to maintain America's reputation. They are even lacking in Yankee adroitness or they would at least copy some of the good English designs.

Will not some of the live, enterprising, inventive men found in all branches of mechanical engineering but this one, take hold of the gas engine question? There is a splendid field for the exercise of true business capacity. They need not fear patents. In fact there is scarcely an American patent on a gas or gasoline engine which would be found useful in placing the manufacture of those machines on a proper commercial basis. The modern gas engine is principally valve gear, and apparently the manufacturers have competed with each other for the most complicated and costly contrivances with which to accomplish a simple mechanical act. These wonderful mechanisms must be relegated to the relic chamber before much progress can be made in cheapening the cost of the gas engine and in adapting it to the multifarious uses for power in this country.

ELECTRICITY IN BITUMINOUS COAL MINING.*

The subject of mining coal by the aid of machinery has received renewed consideration each year, as its importance has become more apparent to the industry. This is especially true since the recent industrial depression has fallen upon the commercial world. Coal has been mined in the State in this way to a greater or less extent during the past seventeen or eighteen years, but not until within the past two years has it become plainly manifest that upon the present basis governing the relations of pick to machine mining the latter has such a decided advantage. It is believed that within this period the subject has received more attention than during any other period since its inception. While this is true, the subject of mining coal by the aid of machinery is by no means of recent birth. The records in the U. S. Patent Office show that as early as 1858 it had materialized to such a point as to be considered patentable.

These patents exhibit the range of thought over which inventors have gone in their endeavors to produce coal by the aid of mechanics, and with what eagerness they have tried to solve a problem that even to-day retains many mysteries. To those who are familiar with the progress made in this branch of industry, the small percentage of the claims which have been found to possess merit will appear quite startling. It is possible that the machines of many of the early inventors fell short of success for want of suitable power with which to operate them, the science of electricity being in a primitive condition and the air compressors being very imperfectly understood. For this and reasons hereinafter considered, it is doubtful if the number of economic mining machines on the market at the present time will exceed a half dozen, and it is certain the number can be represented by a single digit.

There are many reasons why the energy of so many inventors has not been crowned with greater success. One is, that mining machines are operated in caverns of Egyptian darkness in which even inventors who have this problem under consideration rarely enter, hence the machines escape the gaze of the inquisitive mechanic who is constantly prying into ingenious devices which are exposed to the light of day. This results in the skilled mechanic and the inventor having little or no knowledge as to the requirements of a successful mining machine or to the amount of labor that it must perform. They are equally ignorant as to the rough usage that it must withstand in order to reclaim a ton of coal with economy to the mine operator. Although the most intelligent and skilled miners, thoroughly versed in their vocation, are usually selected to operate the mining machines, as miners they are entirely wanting in the knowledge of mechanics, and therefore unable to calculate as to the amount of additional strength required, or of the form or place to apply it in order that the machine may withstand the resistance offered by the coal. It will be readily seen that the mining machine is thus deprived of suggestions, alterations and improvements that would be offered by both mechanics and inventors were it operated where it would be exposed to the public eye, as are other labor-saving devices. Even since the introduction of the first economic machine, which was about 1876 or 1877, there have been scores of machines patented and placed on the market, many of them possessing features that would have been of great value to the mining industry had they been fully developed, but upon trial they were found to be too frail, and after a number of vexatious delays, caused by breakage, they were consigned to the scrap pile, and the disheartened inventor found himself forced to abandon his hope of reward and return to his former vocation. Had he been possessed of a knowledge as to the units of work that are required to undercut the coal he would have increased the factor of safety in his calculations and the result might have been more satisfactory.

But few coal veins are adapted to machine mining at all, and in a still smaller number can the present type of standard machine be used with economy. For profitable mining the roof must be strong and free from slips or bell-shaped balls. Especially is this true of the rotary bar or of the end-cutting chain machine, either of which cannot be well operated if the props are set less than twelve feet from the coal face. The floor of the coal vein must be nearly, if not quite, level to admit of the successful working of machines. There is no instance within the writer's knowledge where the mining machines have given satisfaction when operated on an uneven floor. The thickness of the vein has been considered as the index by which its adaptability for the introduction of mining machines is to be determined, and, with but few exceptions, no attempt at an installation has been made except in the very thickest of the veins; and so machine builders have designed only for the mining of high coal. For this reason the practicability of using machines in reclaiming the coal in thin veins still remains undecided. This is largely owing to the fact that the fiber of the coal is as firm in the thin veins as in the thick, so that the power required to undermine the coal remains the same, hence the weight of the machine must be as great for one as for the other. The diminished space in which to use the bars by which the machine is moved, also the necessity of using a shorter bar, thus diminishing the leverage, makes the moving of the machine very laborious and slow, and thus diminishes the opportunity of profit that might be derived from their installation. With a view of widening the field of machine mining, some manufacturers have turned their attention to the designing of a machine that would be of such a height as to not come in contact with the roof while being moved, but the weight of the machine was so great that it offered no encouragement to the operators in thin veins. The mere fact that a machine is of a height that will permit of its being readily moved is no guarantee that it can be profitably used in that vein. It is an old rule in mining to make the undercutting the same depth as the coal vein is thick. If a proper amount of powder is then judiciously used the coal will be liberated in its best possible form.

The present type of bar or chain machine is designed to undercut from six to seven feet, and where the vein is from eight to twelve feet in thickness this is, of course, much less than the rule would require. In such an instance great difficulty has been experienced in producing merchantable coal, owing to its flaking off in thin slabs so shattered as to not stand handling.

It has been found that a seven-foot machine must be much heavier than one that is designed to undercut but six feet, hence it is the writer's belief that if in these veins the machines were designed to undercut from three and one-half to four and one-half feet, as the thickness of the vein would demand, it could be so reduced in weight as to be readily moved into position. Such a machine would be designed to undercut the full thickness of the vein, and the coal thus produced will enter the markets in as good form as if it were the product of pick mining.

The early installations of mining machines, beginning about 1877, were confined to the use of compressed air as a motive power. This continued until early in the year of 1889, when electricity was first successfully applied to a rotary bar machine by the Jeffrey Manufacturing Company of Columbus, Ohio. This machine is still in use in the mine in which it was first installed. The ease and economy with which this new power could be conducted about the mine commanded for it at once the attention of the inventor and operator. It placed the employment of the mining machine within the reach of a greater number of operators, and the development of machine mining has gone forward rapidly since that date.

The question of operating mines by electricity has received more discussion during the past six years than any other subject before the mining public. The few years elapsing since the first introduction of electricity have witnessed its successful application to every labor-saving device in the industry in which compressed air had formerly been utilized. Furthermore, it has been known that the amount of power required to operate the mining machines has been reduced; also that the construction of the mining machine has been improved, and that new and improved machinery has been designed to attack the coal in a more advantageous manner. Still there has been no careful investigation of this progress or no published information for which the public has been the wiser. It would seem that the efficiency of the power, its adaptability to the uses of the mine, the amount of it required to do a given amount of work, the loss in transmission, etc., were questions which should have received ere this the most careful investigation and the results placed before the mining public. The absence of this information can only be accounted for on the assumption that the persons who desire it dislike to undergo the necessary hardships and inconveniences, much less to perform the labor, whereby it can be acquired.

---

*Abstract from Annual Report of R. M. Haseltine, Inspector of Mines of State of Ohio.

Pressure Limits in England.

The committee, consisting of Lord Kelvin, Mr. W. H. Preece and Major Cardew, to whom the London Board of Trade referred the many points involved in the discussion of pressure limits, has proposed that where the conditions of the supply are such that the pressure may at any time exceed 500 volts if continuous, or 250 volts if alternating, but cannot exceed 3,000 volts whether continuous or alternating, the supply shall be deemed a high pressure supply. The committee advise that the regulatnioy be amended as follows: "The pressure of a suppls delivered to any consumer shall not exceed 250 volts at any pair of terminals;" "no such conductor shall be at a higher pressure than 300 volts from earth." In Regulation No. 6, the words "or less than 45 volts if continuous, or the equivalents thereof respectively if alternating," are to be omitted.

With reference to the suggested alteration to the regulation for safety, the committee are of opinion that to enable the use of 500 volts continuous pressure between the outer conductors of a three or five wire system with bare conductors laid in conduits, the Board of Trade may give a provisional sanction to an earth connection being applied to one point of the middle conductor in any case in which they are satisfied that a high insulation is maintained on all other points of the system, and that suitable and sufficient means are provided for the immediate detection, localization and correction of any fault of insulation.

The committee consider that in making the above suggestions they have indicated clearly how, in their opinion, the question of limitation of pressure should be treated to adequately secure the safety of the public and to meet the requirements of electric lighting undertakers and the convenience of their customers.

Commenting editorially upon the conclusions reached by the committee, the London *Electrical Review* says:

> "Pressure" now means simply "the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth." By inference, a low-pressure supply becomes one in which the pressure can never exceed 500 volts if continuous, or 250 volts if alternating; a high-pressure supply is one between 500 and 3,000 volts for continuous currents, and 250 volts and 3,000 volts for alternating currents, and an extra high pressure, anything over 3,000 volts, on either system. The pressure may not be changed at any consumer's terminals without his consent. In our issue of a fortnight ago we pleaded for three things that have not been granted, but which we considered vital to the best interests of the industry; these were, that practical and experienced station engineers should be included on the committee, that the meeting should be open to the public, and that no difference should be made between continuous and alternating currents. By the failure to grant these points, we think that the conclusions of the committee are unsatisfactory, and will not be accepted without demur by a large proportion of the electrical engineering profession.

The Storage Battery.[*]

A DISCUSSION OF ITS APPLICATIONS BY THE MEMBERS OF THE A. I. E. E.

ACCUMULATOR ECONOMICS.

BY ARTHUR V. ABBOTT AND FRANZ J. DOMMERQUE.

[The above-named paper, read at the Chicago meeting of the Institute held simultaneously with the New York meeting, dealt with the advisability of storage battery installation by comparing the cost of an electric lighting plant capable of supplying the entire city of London with a steam plant alone or with a steam plant with accumulator regulation. The capacity of this station is based upon load diagrams taken over a year ago.]

The load curve shows a maximum load of 11,600 kilowatts, or 15,700 H. P., and a minimum load of 800 kilowatts, or 1,080 H. P., the load factor being 33 per cent. The items required to determine the expenses would be: cost of fuel per year, cost of labor; cost of supplies and repairs; interest and depreciation on plant. It has been ascertained by Mr. Fritsche that the average load throughout the year is 16.375 per cent. of the maximum load, which in this instance would be 2,571 H. P. per hour, or 22,521,960 H. P. per year; the amount of coal used per H. P. hour being about 1½ lbs. The total H. P. hours would equal 25,587,960 H. P. per year, and the amount of coal used would equal 38,351,940 lbs., or 19,176 tons. The price of coal per ton may be taken at $2.25, then the cost of fuel per year equals $43,146.

The cost of labor is determined as follows: One attendant is required per unit, or five in all, at 25 cents per hour, equals an expense per hour of $1.25. Ten firemen and two helpers at the same rate, or an outlay of $3.00 per hour. This fixes the cost of labor at $4.25 per hour. Add for superintendence $1.50 per hour, obtaining a total of $5.75 per hour, or $50,000 per year. Cost of supplies and repairs is found to be $18,000 in round numbers.

Money is obtainable at five per cent., and the amount necessary to provide for depreciation should not be any more; therefore 10 per cent. is assumed. The cost of steam plant, taken at $64 per H. P. (Emery's value) + ⅛ surplus power, a plant of 17,700 H. P., as required, will cost $1,132,800, 10 per cent. of which is $113,280. The cost of dynamo, switchboard and accessories may be taken at $35 per K. W., or $25.90 per H. P. The cost of 15,700 H. P. will be $395,000, the interest and depreciation of which, on the basis of 10 per cent., will amount to $39,500. The total expense, therefore, per year will be $264,300 for regulation by shutting down part of the plant.

For a plant with accumulator regulation it is calculated that the engine power required under the assumption of 90 per cent. efficiency of the dynamos would be, in round numbers, 6,850 H. P. The accumulator capacity required would be 240,000 ampere hours. From the price list of the Electric Storage Battery Company, a cell of 5,000 ampere hours' capacity costs $375. Forty-eight cells in parallel, or a total of 3,120, would be required, costing $1,092,000. Then interest and depreciation on accumulators equal $109,200.

For switchboards and meters a first cost of 10 per cent. on the accumulators would not be too low, the interest and depreciation on which may be taken at 10 per cent., then the annual expense for switchboard and meters equals $10,920. The steam plant required was found as 6,850 H. P. Taking again the cost per H. P. at $64 + ⅛ surplus power would give $467,840; interest and depreciation at 10 per cent. would give $46,784. The dynamo plant, figured at $25.90 per H. P., would amount to $177,420; 10 per cent. interest and depreciation gives annual expense for dynamos and switchboard as $17,742. The amount of coal used would be 6,141 tons. Then taking the cost per ton again at $2.25, the expense for fuel would be $13,820.

Cost of labor will be found as follows: Three attendants at 25 cents per hour, expense per hour $.75; four firemen and one helper, at same rate per hour, $1.25; plus $1.50 for superintendence, which makes a total of $3.50 per hour, or $30,660 per year. Cost of supplies and repairs equals $5,550 per year; adding all determined expenses, the total per year would be $234,676, as against $246,300 found for regulation by shutting down part of the plant.

DISCUSSION.—(Chicago Meeting.)

Mr. Carl K. MacFadden—We have installed an electric light station of over 400 H. P. in gas engines, and have found in a number of cases that although the battery plant has a capacity of not over 600 ampere-hours it has helped us in a wonderful way when we have had trouble with an engine, and we have found it especially valuable in very light loads, when it would not pay us to run the smallest engine, which is of 80 H. P. In small gas-engine stations there has been considerable attention paid to storage battery auxiliaries. In large gas-engine stations, storage batteries will be used in conjunction with improved types of gas engines, so as to keep the engine up to its best load, for the gas engine ought to be loaded up to its rated load to get its best results, the same as the ordinary steam engine.

Mr. Ludwig Gutmann—The reason that the storage battery business is so well developed in Europe and almost neglected in America can, no doubt, be traced to the fact that in Europe until within the last year or two, with few exceptions, all installations were of the low tension continuous current type. In many places, especially in theaters, it was compulsory to provide means such as storage batteries, to prevent a sudden giving out of light due to defects in machines. On the other hand we find in America the majority of installations of the high tension alternating current order. Here in America there was not such a great need for storage batteries, or, if it existed, it was not satisfied because capital was afraid of master patents.

Mr. M. H. Gerry, Jr.—If a storage battery can be obtained, costing not more than the same kilowatt capacity of a first-class prime mover, having a commercial efficiency of 75 per cent., and a cost of maintenance not greater than six per cent. of the investment, then such a battery can be used in a great many power stations with advantage in point of economy. It is only a question now whether such a battery can be obtained, and a great many practical engineers are looking with considerable interest in the direction of storage battery manufacturers.

The present method of stating the capacity in kilowatt-hours or ampere-hours is not altogether satisfactory. More important than the total capacity in the application to fluctuating loads is the maximum rate at which a battery can be repeatedly discharged without seriously damaging it. A kilowatt rating representing this maximum discharge would be of more value in cases of this kind than the kilowatt-hour or ampere-hour.

Mr. B. J. Arnold—Mr. Perry states that under no circumstances would he recommend the use of batteries, for the simple reason that the gas engine will be found more economical. I think this is rather a broad statement and one which the advocates of this system will have some difficulty in substantiating, for the reason that gas engines working on variable loads are extremely uneconomical, and not only are they uneconomical, but they are very sensitive to changes of load. If the load on a gas engine changes suddenly, it is liable to require immediate attention on the part of the operator to keep it in operation. There is no question in my judgment but that a gas engine plant, installed properly and run on producer gas, will deliver a K. W. hour on the switchboard for less money than a steam engine plant can do it, but in order to do so, the engines must be run at practically a constant load.

---

[*] Abstract of Communications and Discussion at the Chicago Meeting of the American Institute of Electrical Engineers.

Such a plant, working in conjunction with a battery auxiliary, I believe to be the most feasible solution of the power station question, and one which we will probably come to in this country in the near future.

The most important application of batteries to lighting work which I have had to do with is the plant now being installed in the Chicago Board of Trade. In this plant the operating expenses average now about $25,000 per year, using simple engines at 75 lbs. of steam, hydraulic elevators with compound pumps working steam full stroke, and old style belted electric plant with shafting. By increasing the steam pressure to 125 lbs., installing new boilers, new compound engines, and with direct connected generators, electric elevators and a battery auxiliary, we expect to reduce the operating expenses to $15,000 a year.

Between the hours of 9 A. M. and 2 P. M. the batteries act in conjunction with the generator, as the demand is in excess of the capacity of the generator, while from 11 o'clock P. M. until 7 A. M. the entire load of the plant is carried by the batteries without the aid of the generators, thus leaving all of the plant, except the batteries, idle for this period of the twenty-four hours, and necessitating but one attendant during this time, who fires the boilers in the winter for steam heating, and also acts as watchman. With this arrangement, the 75 kilowatt unit operates for a period of sixteen hours at its maximum economical load, and is then shut down and stands idle until the next operating period. From this plant will be operated 1,000 16-C. P. incandescent lamps, four 10 H. P. electric motors, four 30 H. P. electric elevators, and it is expected that one 75 K. W. generator will handle this load economically when the plant is completed.

A battery plant properly built, with sufficient lead to do the work required of it, and properly handled, will prove an economical investment where the conditions are favorable ; but it should be borne in mind that a battery, like every other power-saving device, cannot effect a saving unless the load is such as to warrant its use, which is especially the case on variable electric loads.

Prof. Carhart—Three years ago I had the pleasure of visiting, in company with several other gentlemen, the central stations of London, through the kindness of Professor Silvanus Thompson. One thing that impressed me very much, in comparison with what I have been accustomed to see in connection with storage batteries in America, was the fact that they construct their storage batteries there for durability. The cells were of enormous size and capacity. They were extremely heavy, and intended for actual use. They were not made, apparently, by the manufacturers to make money out of, by selling cheap metal at a high price, but they were made for service and durability. The people in charge of those stations in London which use storage batteries watch them very carefully, and when anything is the matter with them they put them in the hospital. Storage cells remind me of an invalid, requiring great care and watchfulness. They must be taken care of and watched when they are not giving their highest efficiency. They require considerable labor, and this item ought to be added to the account.

I have come across one or two points of scientific interest. It is certain that the internal resistance of a storage battery changes considerably with the length of time that it is discharged. As it is discharged, we have a sulphate formed which has a higher resistance than the active material. This internal resistance will change in the course of charging for half an hour. Then there is another point. You all know that the internal resistance of any primary battery decreases as the current increases. We have been able to get very nice smooth curves. With a storage cell the change is small and is quite difficult to measure, but measurement shows that the internal resistance is lower when the current which we are taking from the battery is larger.

Prof. W. M. Stine—There is good reason for the lack of data for the life and usefulness of storage batteries. Through all the years they have been with us, they have existed in tentative form, and their history is a failure of one form, leading to fresh experiments on others. That they have recently been the subject of large speculation by some of our leading financiers is by no means a convincing argument in their favor. This is neither the first nor the greatest financial combination of its kind, and should it not prove successful it is only adding one more to a long list of disastrous failures. The engineering view of our subject has been frequently and pretty exhaustively presented, but too often by those who have had no practical experience with batteries, and whose estimates of first cost, maintenance and depreciation are far below the actual figures.

A commercially practical storage battery would be one of the greatest boons to electrical engineers. This is undeniable. It does not require any especial foresight to realize the great advantages accruing from their use. The problem of when and how far to employ them is not more difficult of solution than the most advantageous amounts and distribution of copper in distributing circuits. It requires that a sufficient number of load curves be taken to get a reliable average curve. It then remains to determine the size of generating plant to handle the average load, and the addition to this to handle the peaks in the load, allowing sufficient reserve to handle the maximum peak likely to occur. The equivalent in batteries of this reserve portion of the plant can then be calculated. The total operating expense in each case would present no especial difficulty were data at hand which would reliably state the depreciation, maintenance and labor involved by the use of storage batteries. Additional elements would be the enhanced efficiency of the generating plant when run with a nearly constant load of the service and battery combined and the power factor of the batteries, or their efficiency from the generator to the consumer. With such data as outlined, the question of the commercial applicability of the storage battery would be a very simple one. All that would be necessary would be to balance accounts between the two classes of reserve plants. On the one side would be the first cost of generators, engines, boilers and accessories, labor, maintenance, operating expenses and depreciation. On the other, the first cost of the reserve equivalent in batteries, their maintenance, depreciation, operating expenses, labor, and the large number of accessories. Here conscientious calculation would leave but little room for discussion, except on methods and details of installation. If the problem has been fairly stated, then why does the present hesitation to install batteries exist? There is no doubt that storage batteries would prove desirable adjuncts to many power and lighting stations, and would be generally introduced, could any reliance be placed upon such low depreciation as 7½ per cent., as has been recently stated. But American engineers are justly conservative on this latter point. In too many cases the depreciation has reached 100 per cent., or the batteries have been abandoned in a short time.

It is undeniable that a strong sentiment exists in this country against the storage battery. Most of the data obtainable is against it. Under such circumstances it would be wise to make haste slowly, and let the burden of the introduction of batteries rest on the company manufacturing them. The argument that the engineering world wants is not engineering calculations showing a paper economy, but it wants to be granted the demonstration of plates that have stood at least from 1,500 to 2,000 daily reversals on continuous service. A battery of which at least 90 per cent. of its plates could make such a showing would be not a mere curiosity but a most convincing argument.

The general trend of practice is to employ a greater weight of lead per ampere-hour capacity. The heavier plates suffer the same actual loss in pound weight of active material as lighter ones, but can support the loss for a greater length of time. But the proportionate life of a heavy plate, owing to physical disintegration, may in reality be less than the lighter one. The interest on the first cost of the extra lead which is used to ward off the day of final destruction is a direct loss unless the proportionate life of the heavy plate greatly exceeds that of the lighter one.

It has been so often proven that the use of reliable storage batteries is excellent engineering practice that the arguments have become mere platitudes. But where shall we obtain the reliable battery? Certainly it is yet to be proven that it is made in America. Can we point to any make of battery that has stood up under at least five years of ordinary commercial service? Litigation is claimed to be responsible for the non-use of storage batteries in this country. Yet we all know better than this. If a perfectly reliable battery had existed, it would have come to the surface in spite of all lawsuits. The very fact that manufacturers are constantly changing the form of plates, etc., is sufficient argument to show that plates will not stand up under service. Great stress is laid on the extensive use of the storage battery in England, Germany and Switzerland. But here the plants are too modern to prove their ultimate economy.

European practice offers a counter argument. The fact that batteries are used there so extensively shows that they must prove at least a partial success. Let American engineers, then, profit by European experience. Let us go to them for our information.

Another question remains to be decided. Can batteries be profitably sold outright? In many cases the manufacturer has maintained a fostering care over plates installed, and the life shown has in a measure been due to frequent patching up of plates. Among points not sufficiently emphasized by many writers are the great outlay for the numerous expensive accessories demanded by a first-class installation, the constant attention and treating which they demand, and the disagreeable nature of repairs due to handling sulphuric acid.

Determining Center of Light from Photometric Burner.

At the New York meeting of the American Society of Mechanical Engineers, D. S. Jacobus, of Hoboken, N. J., read a paper entitled "Experimental Method of Determining the Effective Center of the Light Emitted from a Standard Photometric Burner," based upon data obtained in testing car lamps in the Department of Tests of the Stevens Institute, Hoboken. In these tests a burner of about six candle power was used as a standard of light. The burner selected was a Sugg Argand gas burner fitted with an opaque screen of the Edgerton pattern which passed over a glass chimney. The opening for the emission of light was arranged so that the top and the lower part of the flame were obscured from view, whereas the horizontal width of the slot was made greater than the diameter of the flame. The horizontal width of the slot was one and one-half inches, and its height was thirteen-thirty-seconds of an inch. The diameter of the opaque screen was one and seven-eighths inches. The back of the screen opposite the slot was cut away so as to prevent reflected light from being thrown back and through the slot.

In this class of a screen and burner, the distances employed in calculating candle power measurements are often measured to the geometrical center of the frame. Any error so involved will be a small one if the illuminated disk of the photometer is used at a considerable distance from the burner and in about the same position which it occupied when the burner was calibrated by means of candles. In these tests, however, the burner had to be used in positions near to as well as far away from the disk, so that it was necessary to determine the effective center of the light which it emitted.

The method of determining the effective center was as follows: The photometer disk was set at a given distance from the candles, and the standard burner was brought to a position at which there was an equal illumination on the two sides of the photometer disk. The distance from the disk to the geometrical center of the burner was then recorded. The disk was then moved to another position, and the corresponding distance from the disk to the burner was recorded. The disk was then set back to its first position and a second reading obtained. It was then moved to the second position, then back to the first, and so on, until a number of readings were obtained. After a sufficient number of readings were taken to eliminate any irregularity due to variations of light emitted from the candles, the results were averaged and the distance of the effective light center from the geometrical center of the flame was found by means of a formula.

The results of the experiments showed that the effective light center of the burner was about nine-tenths of an inch from the geometrical center of the flame and entirely outside the flame as indicated. The candles do not have to be corrected for variations in the rate at which the paraffin is burned. All that is necessary to insure accuracy is to make a number of observations, changing the distance of the photometer disk from the candles each time a reading is taken, as has already been explained, and employing the average figures.

The error involved, if all the measurements were made from the axis of the burner instead of the effective center, both in calibrating and in using the standard burner, would have been as a maximum about ten per cent. in the lamp tests which we made. In these the effective center of the burner was placed at a distance of sixty inches from two standard candles in calibrating the burner, and the minimum distance at which the burner, when used as a standard, was placed from the photometer disk was about twelve inches.

ndro Ainary way of using the burner is to place it sixty inches from two standard candles to calibrate it, and then set it sixty inches from the flame of which the candle power is to be determined, all distances being measured from the axis of the burner. If calibrated and used in this way, there is an error of about three and three-quarters per cent. for a flame of twenty candle power, and of about six per cent. for a flame of forty candle power.

Another way in which the burner is calibrated is to measure the candle power of a uniform gas flame, first with candles and then with the burner, and repeat the two operations until an average figure is obtained. When this is done there is but a small error involved in measuring from the axis of the burner, provided the gas flame which is measured is of about the same candle power as the flame which was employed for calibrating the burner, so that the distance from the standard burner to the photometer disk is about the same in both cases. If the burner is calibrated at sixty inches from a gas flame of twenty-four candles, and is used at the same distance to measure the intensity of a flame of sixteen candle power, there will be an error of about one per cent.

Magnets for Lifting Purposes.

An interesting use of magnetism is being made at the Sandycroft foundry in England. At these works electric cranes are operated from the electric power and lighting circuits, together with electro-magnets, which permit the ready lifting of pieces of iron or steel weighing up to two tons. The magnets constructed for lifting purposes are attached to a crane. One magnet takes 5½ amperes at 110 volts to excite it, at which energy it will support a weight of two tons of iron or steel. A switch controls the supply of current delivered to the magnet. By the use of this magnet, or crane, three men do the work in one quarter of an hour which previously took six men one hour and a half to perform.

TELEPHONE COMPANIES DECLARED TO BE COMMON CARRIERS.

The temporary injunction secured some months ago by Simon Sterne, a New York lawyer, restraining the Metropolitan Telephone & Telegraph Company from removing a telephone from his office because he refused to pay $240 a year for the use of it, has been continued by a decision of Judge Ingraham of the Supreme Court of New York. The action of Attorney Sterne was in the nature of a test suit, brought for the purpose of determining the power of the courts to regulate the compensation that should be paid to the telephone company for the service given.

Mr. Sterne insisted that the rates fixed were extortionate and excessive. The company, on the other hand, insisted that the advance in the rates from $125 to $240 was due to the increased cost occasioned by the improvements in the service. As Mr. Sterne declined to pay the higher rate, the company threatened to remove the instrument from his office. He then instituted proceedings and secured a temporary injunction protecting him in the continued use of his telephone. In his decision Judge Ingraham holds that the injunction must be continued. He says in his opinion:

> There can be no doubt whatever but that the Legislature would have power to regulate the business of this defendant. It is a corporation created by law, and the business it is conducting is of a quasi public character. In this case the Legislature has not attempted to regulate the price that this defendant should charge for the use of its telephones, and the question is presented as to whether or not the courts in the absence of legislative enactment can so control the business of the defendant corporation as to prevent its charging for the use of its telephones a sum that is greater than that proved to be a reasonable compensation for the services rendered.
>
> I think it is clear that at common law in the absence of legislative enactment a common carrier is bound to furnish transportation to the public for a reasonable charge, and the courts, upon a proper application made, may determine in each case what is the proper and reasonable compensation to be paid to the corporation and compel the corporation to furnish such transportation on the payment of such reasonable compensation.
>
> I am inclined to think that this duty of the courts extends to a business carried on under the authority of law which is in its nature a public business affected with a public interest, and that the transmission of intelligence by electricity is a business of such public character that it is to be exercised under public control.

The question of rates, Judge Ingraham thinks, can best be determined by the examination of witnesses upon a trial of the issues.

The Government Given More Time in the Berliner Case.

Judge Colt, of the United States Circuit Court of the Massachusetts District, has granted the United States until May 31, 1896, in which to take evidence in rebuttal in the case of the United States against the American Bell Telephone Company and Alexander Graham Bell, in which the question of fraud in procuring the Berliner patent is raised.

Judge Colt refused to limit the Government to the question of fraud raised. The Government has taken a vast amount of evidence in support of the claim of Daniel Drawbaugh, and the defendants have taken countervailing evidence on the same issues. The Government now wishes to take evidence to rebut the defendants' evidence, and the Court has given time for that purpose. It did not restrict the Government from taking evidence on the question of alleged priority of invention, which it could have done had it granted the request of the defendants.

In the suit of the city of Tacoma, Wash., against the Tacoma Light & Water Company, the jury awarded $787,000 damages to the city. Three years ago the president of the Light & Water Company secured, by what has been declared by the Chamber of Commerce of Tacoma to be the most corrupt election ever held in the city, the sale to the city of the water plant, including an electric light plant, for $2,080,000. Fraud, bribery, misrepresentation and ailure to deliver what was promised to sell resulted n a suit for $1,000,000 damages.

Multiplex Telephony.

To the current number of the *Sibley Journal of Engineering*, Mr. Kempster B. Miller contributes an article on the above subject, being mainly a description of the systems patented in the United States by William W. Jacques of Massachusetts and Maurice Hutin and Maurice Leblanc of France. The first of these systems is founded upon the principle that the human ear can readily detect a sound lasting but a very minute part of a second, while it will fail to notice an interruption of much longer duration in a sound continuous except for such interruption. In this system the line terminates in a group of reeds adjusted to vibrate rapidly and synchronously between contact plates attached to multiple telephone receivers. The rate of vibration is so rapid that the switch arms are not removed from either of their contacts for a period greater than one-hundredth of a second at a time. Since a sound occupying but one-hundred-and-five-thousandth part of a second can be heard, while an interruption lasting as long as one-hundredth of a second in a sound continuous except for such interruption cannot be detected, it follows that a conversation can take place between any pair of telephones attached to the reed vibrating apparatus.

The second system depends for its operation upon an analysis and synthesis of sound, to accomplish which the inventors make use of the fact that an alternating current of one particular frequency only will be efficiently transmitted over a circuit having a given coefficient of self-induction, resistance and static capacity, while currents of all other frequencies will be so greatly reduced as to be relatively insignificant.

A combination of a condenser and a self-induction coil, called by the inventors an "electric resonator," is used, it being understood that a circuit containing such a combination will select one particular frequency of alternating current, to the exclusion of all others, just as a Helmholtz resonator will select a particular frequency of sound vibration.

To each end of a line wire are connected selectors, each composed of a number of parallel circuits containing condensers and self-induction coils, or in other words, a number of resonators. To the other side of each selector is connected respectively a telephone set consisting of a receiver, an induction coil and a local circuit containing a microphone and a local battery. The various resonators of the selectors are tuned to frequencies of 100, 105, etc., to 1,100 alternations per second, each selector therefore having a range corresponding to a fundamental tone and nine of its harmonics.

If a sound be uttered in front of the microphone connected to one of the selectors, an alternating current will be generated in the usual manner in the secondary of the induction coil attached to it. Of all the components of this complex wave only ten will be transmitted through the selector to the line wire. At the other end of the line these components will only find passage through the resonators of the corresponding selector, and will be barred from passage through the other selectors, these latter having no resonators tuned to any of these particular frequencies. After passing through the particular selector, the components are reunited and produce in the corresponding receiver at the receiving station a sound closely approximating that uttered against the microphone at the sending station.

The current selector corresponding to any telephone nstrument therefore transmits to the line ten of the components of the complex current generated in its induction coil, and the corresponding selector at the opposite end of the line picks out this particular ten from all others which may be coming over the line from this and other instruments, and recombines them into a complex resultant alternating current which is capable of producing in the receiver at the receiving station a sound almost but not quite a correct reproduction of the original.

Electrical Reduction of Colorado Ores.

W. S. Stratton the millionnaire mine owner of Colorado, has contracted for the equipment of a complete electrical reduction plant to be installed at one of his extensive ore mines either at Cripple Creek or Colorado City. The equipment will consist of a direct connected generator having a capacity of 2,000 amperes at 25 volts. The ore will first be crushed, then placed in vats to be acted upon electrolytically the process being similar to that employed at the Anaconada mine. In this plant there are seven generators. Four give a current of 1,200 amperes at a pressure of sixty volts and three give 750 amperes at 140 volts. The tanks each contain 100 plates placed in series. The tanks are connected up in sets of five, and these sets are connected with the feed wires in multiple. The original plates are cast in the shape of a very broad T, the two flanges at the top being the supporting points and the bottom going into the tank. The solution in this tank is made up of copper, gold and silver, mainly copper. While running, the solution is kept up to almost saturation. The action of the plates is for the solution to dissolve copper off the first plate and deposit the same amount on the bottom of the second, and at the same time dissolve off a portion of the face of the second and deposit this on the rear of the third, and so on. The first plate, instead of being copper, is lead and does not contribute to the solution. The backs of all the other plates are blackleaded, so that the copper may strip when wanted. By keeping the copper solution up to its highest point in value, as is readily determined by the use of a hydrometer with frequent assays as a check, the copper dissolves off the face of the plates only in very small proportions, while the amount deposited on the rear is extremely great.

When the solutions are first made up, all the metals present are dissolved, and, if they were all deposited on the plate there would be no advantage. As nearly all metals require a slightly different current for plating or depositing, the current is so regulated that the copper only is deposited and the gold and silver are dropped to the bottom of the vat as slime, which is cleaned out frequently and refined. At the same time the solutions themselves grow saturated with these metals, and they are also at long intervals taken out and the contents precipitated and recovered. By the electrolytic process copper of more than 99 per cent. fine can be produced.

Chicago Electrical Association.

The Chicago Electrical Association held its third meeting this season on the 3d inst. The paper of the evening was by W.Clyde Jones, on the "Protection of an Invention," and was a very concise and complete statement of facts regarding American patent laws and customs. The paper was discussed by W. R. Garton, Thomas G. Grier, S. B. Jamieson and others. Following the paper the election of officers for the ensuing year was held and resulted in the election of W. Clyde Jones president, S. G. McMeen vice-president, J. R. Cravath secretary, F. S. Hickok treasurer.

There has recently been a great increase in interest and membership of this association, which promises to take a prominent place among the local societies in the largest cities in the country.

International Congress of Applied Chemistry.

The second annual meeting of the International Congress of Applied Chemistry has been arranged to take place in Paris next year under the patronage of the French Government, and will be accompanied by an exhibition of chemical and agricultural industries. The congress will be divided into 10 sections, of which Section X is devoted to electro-chemistry, and will be presided over by M. Moissan. The secretary is M. Gosselin, and among the vice-presidents are MM. d'Arsonval, Hospitalier, Javaux, Mascart, etc. The following is the programme of subjects to be discussed : 1. The laws of electrolysis, with the determination of the constants involved (the resistance of electrolytes in solution and in a state of fusion, the effect of temperature, the E. M. F. of polarization, etc.). 2. The use of electrolysis in analysis. 3. (*a*) The preparation and use of insulating materials, including indiarubber, guttapercha, and their substitutes ; (*b*) the resistance, temperature coefficient and electric properties of alloys. 4. Electrolysis in the alkali trade (chlorate of potash, soda, bleaching powder, etc.). 5. The use of electrolysis in organic chemistry (rectification of alcohols, sugar manufacture, sterilization of impure water, synthesis of organic compounds, etc.). 6. Electrolysis of metals in the wet way. 7. Electrolysis of fused salts (sodium, magnesium, silicon, lithium). 8. The electric furnace (carborundum, calcium carbide, silicon boride, titanium, etc. 9. Thermo-electric work (welding, electric heating, etc.).

OBITUARY.

Alfred E. Beach, who died of pneumonia Sunday morning, was the son of Moses Y. Beach, who established the *N. Y. Sun* and conducted it for many years. Mr. Beach was born in 1826 in Springfield, Mass. In 1846 he and his former schoolmate, Orson D. Munn, founded the firm of Munn & Co., and became the proprietors of the *Scientific American*, which at that time was the only weekly journal of its kind published in this country. For nearly fifty years Mr. Beach was active in the editorship of the *Scientific American* and in the direction of the extensive patent business of the firm. He leaves a widow, one son and a daughter.

GENERAL NEWS.

What is Going On in the Electrical World.

Sullivan, Ill.—J. H. Baker's electric light plant was completely destroyed by fire on the 23d ult.

Manlius, N. Y.—The electric lights were turned on in this village for the first time a few nights ago.

Milwaukee.—Negotiations are pending at South Milwaukee for the establishment of an electric light plant.

Winchester, Ky.—An advertiser whose address is "Electricity," Winchester, wants a 300 light 110 volt dynamo.

Columbus, Ga.—The Columbus Railroad Company intends to expend $50,000 in the enlargement of its electric plant.

Coloma, Mich.—Leading business men are agitating the introduction of electric lights and electric cars in this town.

St. Louis.—Mayor Walbridge has signed the bill granting the Manchester Road Electric Railway Company a franchise.

Northfield, Minn.—The Northfield Heat, Light & Power Company have their new electric light plant ready for operation.

Watkins, N. Y.—Surveyors have been at work recently on the proposed electric road here, reviving interest in the project.

Ellwood City, Pa.—Council has passed the electric light ordinance over the veto of the burgess and a plant will be put in as soon as possible.

Lancaster, Wis.—Hobart S. Bird, of Madison, has been here making an investigation as to the advisability of starting an electric light plant.

Boulder, Col.—The Western Electric Transit & Power Company will locate its plant near the mouth of Boulder canon and will run it by water power.

New York.—The net earnings of the Edison Electric Illuminating Company of New York for 1895 will show about 8 per cent. earned on the capital stock.

Dublin, Ga.—An election will be held here on the 12th inst. to decide the question of bonding the city in $25,000 for waterworks and an electric light plant.

Gainesville, Fla.—The Gainesville Electric Company wants a new or second-hand plant for forty 2,000 C. P. arc and one thousand 16 C. P. incandescent lights.

Lowell, Mich.—The vote at the recent election in favor of expending $23,000 for the construction of an electric lighting plant by the city was 363 ; against, 68.

Warren, O.—The recently-incorporated Cleveland & Chagrin Falls Electric Railway Company has announced its intention of extending its proposed line to this place.

Guthrie, Okl.—The local electric light plant has been largely extended by the recent addition of a complete new lot of machinery, including dynamos and switchboard.

Kansas City, Mo.—It is stated positively on good authority that as soon as the entanglements of the Union cable line are straightened out the road will be equipped with electricity and added to the street railway system of the city. M. M. Broadwell, of New York City, who is now in the city, says that he came here to see the line put in operation under the new system.

Middletown, Conn.—It is stated that the Middletown Electric Railway Company will shortly erect a new power house equipped with all the latest improvements.

Freeport, L. I., N. Y.—The people of this place are anxious to have electric lights and are urging the trustees to have an election held to get a vote of the public on the question.

Alexandria, La.—Bids will be advertised for by this city shortly for a 50 K. W. alternating dynamo, engine, boiler, etc. Address A. C. Jones, superintendent electric light plant.

Staunton, Va.—Arrangements have been made to change the motive power of the City Railway Company from mules to electricity, and work on the new system will begin at once.

Carlisle, Pa.—Chief Burgess J. M. Bretz, of Camp Hill, has vetoed the ordinance providing for electric lights for that borough. The ordinance was passed some time ago by council.

Rush City, Minn.—The Minneapolis Electrical & Engineering Supply Company have completed the erection of an electric light plant here which is pronounced one of the best in the State.

Bangor, Me.—At a meeting of businesss men in this city, it was unanimously voted to aid as far as possible the construction of the proposed electric road to Charleston and East Corinth.

Niagara Falls.—Petitions are being signed by the property owners throughout the city in favor of having another electric street railway line. Gen. Benj. Flagler is interested in the new company.

Charlevoix, Mich.—The village council has granted to Charles Gabriel, manager of the electric light company, a franchise for an electric railway to connect this place with neighboring resorts.

Chatham, Can.—Thos. W. Horn and H. A. Beatty, of Toronto, have been conferring with our representative citizens on the question of establishing an electric street railway in this city with extensions north and south.

Flint, Mich.—From recent manifestations it is almost certain that the proposed electric railway from Flint to Fenton, via Long Lake, the franchise for which is held by T. Nolan, of Saginaw, will be constructed at an early day.

Toronto, Can.—The Toronto, Hamilton & Niagara Falls Electric Railway Company has given notice of application for a charter at the next session of Parliament. A number of villages would be connected by the proposed route.

Youngstown, O.—The Orient Electric Company has received an order through a New York exporter for incandescent electric lamps for a big Russian order, and will, it is said, be kept working overtime on this order for three months.

Montague, Mass.—The Montague Street Railway Company has applied to the selectmen for permission to build an electric railway from Montague Center to connect with the present system at Lake Pleasant. There is little doubt that the franchise will be granted.

San Bernardino, Cal.—If an investigation now in progress shall result satisfactorily, the citizens of San Bernardino will be given an opportunity to express their individual opinion on the subject of establishing a municipal electric lighting plant by voting for or against the issuing of bonds.

Newark, N. J.—A good many business men are advocating the building of an electric belt line railroad here for the transportation of freight as well as passengers, and an effort will be made to have an act passed permitting the carrying of freight within certain limits for the convenience of manufacturers.

Baltimore, Md.—It is probable that the City Passenger Railway Company will shortly decide to change the motive power on the Blue Line from cable to electric. Some time ago President Franklin stated that such a change was desirable in order to reduce operating expenses and provide for future suburban extension.

Montclair, N. J.—The following changes have been made in the officials of the Montclair Light & Power Company : William Winslow Ames has been elected president, vice Whiting G. Snow, resigned, and Philip N. Jackson, vice A. C. Fisher, resigned. C. D. Backus and George R. Baker have resigned from the board of directors.

Rochester, N. Y.—The board of supervisors have awarded the contract for the gas and electric light fixtures for the new court house to Archer & Pancoast, of New York. A member of that firm says that the fixtures which his house will furnish will be reproductions of the finest work in buildings of a like order of architecture in Europe.

White Plains, N. Y.—A franchise has been granted to the Port Chester, Rye & White Plains Electric Railroad to construct a line through Westchester avenue from the monument to the town line. Franchises will also be asked of the towns of Port Chester, Harrison and Rye. The company agrees to begin work in sixty days and have the road completed in six months.

Reading, Pa.—The deal in which the newly organized United Traction Company secures control of the various lines of electric railways formerly operated by the Reading Traction Company was concluded last week at a meeting of the shareholders at which the leases were ratified. The new company controls all the electric lines in Reading with the exception of the Reading and Southwestern.

Cripple Creek, Col.—An enterprise of great importance to Cripple Creek has been inaugurated by Omaha capitalists, who have organized the Cripple Creek Power & Mining Company, for the purpose of generating electric power at Florence and transmitting it to this camp. It is proposed to furnish light as well as power to mines or manufacturing enterprises at a rate which will enable them to be operated much cheaper than at present.

Brooklyn, N.Y.—Mayor Schieren's veto of three solution granting a franchise to the State Electric Light & Power Company was not sustained in the board of aldermen.—The application of the Brooklyn City Railroad Company to annul the city ordinance regulating the speed of cars has been denied by Judge Cullen, of the Supreme Court, who holds that the common council had not surpassed its vested powers in passing the ordinance.

Harrison, N. J.—The bids for lighting the streets were as follows: Fort Wayne Electric Light & Power Company, 75 arc lights of 2,000 C. P. each, 33 cents per night, under a five years' contract; Kearny Electric Light & Power Company, same number of lights under a five years' contract, 27½ cents per night; People's Electric Light & Power Company of Newark, 28 cents per lamp a night. Each proposal was accompanied by a certified check for $3,500.

Cleveland, O.—The "Press" says: "A trip that cannot be duplicated anywhere in the world will be possible, next summer, as the result of the development of electric railway systems by capitalists in Cleveland and Buffalo. Informal plans have been discussed by representatives of the Akron, Bedford & Cleveland Electric road and some Buffalo people, by which trips may be made next summer from Akron to Niagara Falls entirely by electric road and boat."

Washington, D. C.—The "Times" states that there "are unmistakable surface indications to the effect that preparations are being made for the consolidation of the Columbia and Metropolitan street railways, the reorganized company to be known as the Metropolitan Electric Traction Company. This proposed street railway deal is equal in importance to the transverse arrangement by which the Chevy Chase line swallowed the Washington and Georgetown."

Provo City, Wash.—It now seems certain that before another summer passes there will be a mammoth power plant erected near the mouth of the Provo Canon. The location of the plant has already been determined on and the surveys and plottings accepted by the Provo River Power Company, of which L. L. Nunn, of Telluride, Col., is the chief manager. It is thought that sufficient water power can be developed at the selected point to generate electricity enough to supply power and light to all the mining settlements of Utah.

Portland, Conn.—George C. Raymond, secretary of the Connecticut Engineering Company of Norwich, Charles Potter, a well-known capitalist of the same city, and George Hunt have completed arrangements for the purchase of the entire stock, also the plant and fixtures of the practically defunct Portland Electric Light Company, established two years ago. The company will be reorganized under entirely new management, and the plant will be enlarged and put in operation as soon as the necessary work can be completed.

St. Louis.—Another electric railway line has been projected to extend westward through St. Louis county from the city limits to St. Charles, over the St. Charles rock road. Surveyors have been engaged surveying the route, and their reports as to the feasibility of the line and the cost of construction have been most favorable to the enterprise. The promoters are Messrs. Frank Thompson, F. C. Fisher, Robert Lucas, T. M. Kilby, H. Damon, J. C. Miller, George Wise, George Brown, E. T. Thomas, James Dawson, John Shackelford and J. C. Ghio.

Lewiston, Me.—The Lewiston & Auburn Electric Light Company has leased the valuable water power on the Little Androscoggin river known as the Gay power, situated near Littlefield's Corner, formerly occupied by the American Light & Power Company. This water privilege has a fall of 24 feet and is estimated to furnish at least 400 H. P. The steadily growing demand for electric lights and electric power has made it necessary for this company to obtain increased power in some direction, and the location of this privilege is so favorable in connection with their present plant that it is considered an especially valuable acquisition.

New Orleans.—The Gulf Coast Electric Company, organized about a year ago, have recently held consultations with capitalists in regard to their plans and shown much earnestness in promoting the scheme they have in view, which is the building of an electric railway, following the Gulf Coast line, between the towns of Pass Christian and Biloxi, with spurs to the Louisville & Nashville at Pass Christian, Long Beach, Mississippi City and Biloxi. The officers of the company are: President, A. M. Dahlgren; first vice-president and manager, James B. Cable; second vice-president and general auditor, G. W. Bennett; secretary and pro tem. treasurer, J. V. Ross. The capital stock to be subscribed is $250,000.

New Haven, Conn.—At the annual meeting of the Connecticut Electric Lighting Association, held here on the 27th ult., the following officers were elected: President, James English, of New Haven; first vice-president, C. H. Merritt, of Danbury; second vice-president, L. F. Curtiss, of New Milford; treasurer, A. M. Young, of Norwich; directors for two years, J. E. Sewell, of Waterbury, and A. S. Hurlburt, of Norwich. E. S. Breed, of New Britain, and Charles D. Sherman, of Meriden, were appointed a committee to draft suitable resolutions on the death of the late James A. Hadley, superintendent of the Meriden Electric Light Company and first vice-president of the association. A. J. Purington, superintendent of the Stamford Gas and Electric Company; Charles D. Sherman, superintendent of the Meriden Electric Light Company, and John E. Sewell, general manager of the Waterbury Traction Company, were appointed a committee to prepare a joint paper on various matters of interest pertaining to electric lighting, to be read at the June meeting.

TELEPHONE AND TELEGRAPH.

Climbed the Wrong Pole.

Judge Baker of the Federal Court at Indianapolis, Ind., has handed down an opinion in the case of Thomas Dickson versus the Western Union Telegraph Company, involving a somewhat novel point. Dickson was a line inspector for the defendant, and while in pursuance of his regular work climbed a pole belonging to the Central Telephone Company. While astride of a cross-arm the arm broke, precipitating Dickson to the ground and injuring him. He sued the Western Union Company for $5,000 damages.

In deciding the case the court held that the plaintiff, as an employee of the Western Union Company, and not of the Central Telephone Company, was not responsible to his employer for the condition of a pole belonging to the latter company, and that his act in climbing the pole was entirely voluntary on his part; that his employer was not responsible to him for damages for injuries, which were manifestly occasioned through his voluntary action and which were received while he was on a pole which the Western Union Company did not own and over which it could not have had control.

To Reduce Rates in New York State.

The Kings County Pharmaceutical Association of New York City, in co-operation with other commercial organizations throughout New York State, has completed the draft of a bill, to be shortly introduced in the Legislature, providing for the reduction and regulation of telephone rates. The bill provides that in cities of 1,000,000 and more inhabitants the rate shall not exceed $125; in cities of 500,000, not to exceed $85; in cities of 100,000, not to exceed $48; in cities of 20,000, not to exceed $36; in cities and places of 8,000, not to exceed $30, and in all cities of less than 8,000, not to exceed $27 per annum.

The charge at pay stations for local messages is fixed at ten cents for the first five minutes and five cents for every succeeding five minutes or fraction thereof. It is also proposed that no yearly patron or subscriber having and paying for a telephone at his own place, office or residence on the unlimited service rate shall be charged for the use of a telephone at any public or pay station when used by him or his employees in his business exclusively. All such patrons, subscribers and customers shall be furnished with cards or certificates showing their telephone number or numbers and entitling them to such free use of public or pay stations.

Telephones in Iceland.

The telephone has apparently got a footing in Iceland. It is said that an American is laying a line between Reykyavik and Akureyri. It is also reported that an Englishman has submitted to the Althing a proposal for a telegraph cable between Iceland and the Shetland Islands. The funds necessary for this undertaking have already been secured, and Great Britain, Denmark and Iceland will jointly guarantee those who advance the money an interest of 6 per cent. for a number of years.

The New French Cable.

The Budget Committee of the French Chamber of Deputies has approved the draft convention concluded between the Government and a French cable company for the laying of a new cable between Brest and New York, with an extension to the West Indies, and thence to Para in Brazil.

Telephony in Austria.

The official statistics just published show that the telephones in Austria now number 17,404. Of these the State controls 9,295 and a private company 8,109. There are 121 town systems with 8,723 subscribers under State control. In private hands there was only the Vienna exchange with 7,924 subscribers.

The Marseilles Telephone Company, Marseilles, Ill., has certified to an increase in its capital stock from $2,000 to $4,000.

The finance committee of the city council of Alexandria, Va., has accepted the bond of the Home Telephone Company. The company will begin the construction of its plant at once.

An ordinance has been introduced in the council of East St. Louis, Ill., providing for the granting of the franchise to M. M. Stephens, H. D. Sexton, Paul W. Abt, Thomas L. Fekete and W. J. Kurtz to operate a new telephone system. The provisions of the ordinance state that a bond of $10,000 must be given by the company receiving the franchise; telephones must be furnished free for the Mayor's residence and all public offices. The ordinance fixes the rates of rental at 50 cents per week for each telephone in places of business and 25 cents per week in residences.

The Southern Bell Telephone Company has been granted permission and will at once begin the work of laying an underground system in Savannah, Ga.

The New York & New Jersey Telephone Company has declared a quarterly dividend of 1¼ per cent. and an extra dividend of 1 per cent., payable January 15 to stockholders of record of January 4.

The telephone line at Seneca Falls, N. Y., is to be largely extended through Seneca county south, touching six different towns and connecting with Ithaca.

A new telephone company is being organized at Syracuse, N. Y. The Mason-Maxwell instrument will be used.

The Bell Telephone Company of Buffalo, N. Y., has established a rate of $30 for 336 messages, conditioned upon prompt payment of bills.

The Postal Telegraph Company is rapidly adding new offices all over the United States. The following have recently been opened: Evansville, Ind.; Paris, Ky.; Vincennes, Ind.; Lexington, Ky.; Cynthiana, Ky.; Falmouth, Ky., and Albany, Ga.

The People's Telephone Company of Knoxville, Tenn., will erect a line to Chattanooga, Sevierville and Maryville as soon as winter breaks.

The Valley Telephone Company, which has assumed the franchises recently granted the Saginaw Valley Telephone Company in Bay City, West Bay City and Saginaw, Mich., is selling stock and making preparations to construct the exchanges under its franchises.

The York Telephone Company, of York, Pa., elected Dr. C. A. Eisenhart president and Charles Frick secretary and treasurer. The company will establish telephone connection with Baltimore, Harrisburg and intervening places of importance.

The Circuit Court at Dayton, O., has declared that the Central Union Telephone Company has no right to use the streets or alleys in that city. The company had a franchise for ten years and neglected to have it renewed about two years ago. No one molested or disputed its right to the streets until a rival company was organized and applied for a franchise. The Central Union Company objected and in turn was itself ousted by the court.

The North American Telegraph Company and the city of St. Paul, Minn., disagree regarding the possession of the conduit used by the telegraph company in the streets of that city. The company has been under the impression that it owned this conduit, having purchased the franchise from the National Conduit Company, which constructed it. But St. Paul claims that the National Company did not have a perfect title to the franchise because the stipulated number of miles had not been built within the time specified by the contract with the city.

New Companies Incorporated.

The Southwestern Telephone & Construction Company, Dodgeville, Wis. Capital $2,000. Incorporators: Henry Halverson, John M. Reese and George E. McAfee.

The Henderson County Telephone Company, Stronghurst, Ill.—to operate a telephone exchange. Capital stock, $2,500. Incorporators: J. O. Anderson, J. F. Mains, Orin L. Dunsworth, T. J. Hunter, E. H. Allison, E. B. Campbell and L. M. Loomis.

The Carolina Mutual Telephone & Telegraph Company has been incorporated at Charleston, S. C., with a capital stock of $30,000. E. M. Bailey is president, Moultrie Mordecai vice-president, and R. B. Lebby secretary and treasurer.

The Orange Telephone Company has filed articles of incorporation at Newark, N. J. The company proposes to establish a telephone service for the cities, towns, boroughs and villages in Essex county, N. J. The capital stock is placed at $250,000, and business is to be begun at once with $100,000. The incorporators are Edward P. Chamberlain, of Brooklyn; Merrit S. Middleton, of Point Pleasant, N. J., and Charles H. Johnson, of Jersey City.

COMMERCIAL PARAGRAPHS.

The Westinghouse Machine Company has declared a quarterly dividend of 1½ per cent. on the preferred and common stock.

The general office of the Indiana Rubber and Insulated Wire Company has been removed from Marion, Ind., to the factory at Jonesboro, Ind.

Mr. Charles D. Shain's New Year's greeting comes to hand as usual, wishing good luck to every one for 1896.

N. L. Norris, of Warren, O., has been elected secretary, treasurer and general manager of the Orient Electric Company of Youngstown, O., vice C. O. Shatto, secretary, and Dallas Dennison, treasurer and general manager, who recently resigned. The company recently made a large shipment of incandescent lamps to Russia.

The Standard Underground Cable Company has declared a quarterly dividend of 2 per cent. payable January 10.

The Falkenau Engineering Company, Ltd., of Philadelphia, has removed its offices to 711 Reading Terminal Building in that city.

A Factory Outfit Wanted.

C. A. Merritt, of Birmingham, Ala., inventor of the "Merritt" incandescent lamp, is organizing a company to manufacture lamps and other electrical appliances. He would be pleased to have manufacturers send him catalogues and prices on an outfit for a factory, also supplies for manufacturing.

The Victor Motors.

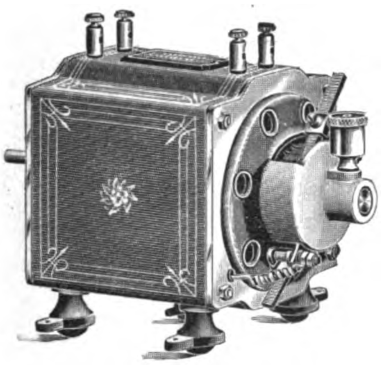

FIG. 1.

The Victor Electric Company, 87 Washington street, Chicago, has placed on the market a line of small electric motors adapted to a multiplicity of uses. These motors are compactly and neatly built and possess a number of valuable features. In Fig. 1 is shown a one-sixth shunt wound motor of stationary type. In Fig. 2 the motor is shown to be mounted upon a fan stand and having other accessories of the fan motor. The general plan of construction is the same in both types.

For this fan motor it is claimed that it is so constructed as to be proof against accidental damage; it is easily repaired, all parts being interchangeable; the motor has no external magnetism whatever; it makes no noise; it will outwear any other; uses only one ampere of current at 110 volts, and may be readily attached to any lamp socket without extra wiring.

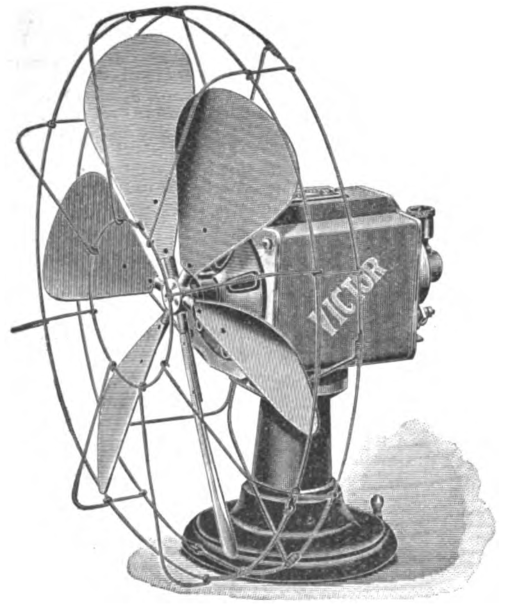

FIG. 2.

In addition to the above-named types of motors the Victor Company has perfected a complete electrical dental engine consisting of a motor with foot-controlling switch, extension bracket, pneumatic plugger, etc., the use of which enables a dentist to entirely discard the foot engine.

Designs and patterns are now being prepared for motors and dynamos of all sizes. By May 1st the company will be prepared to ship all sizes up to 5 H. P.

Industrial Providence.

In a recent souvenir edition of the Providence *Telegram*, comprising 42 pages, a full page is given up to a description with illustrations of the institution known as the American Electrical Works, one of the leading industries of the city.

One of the illustrations shows the barn in which Mr. Eugene Phillips, twenty-five years ago, was turning out wire chiefly by his own handiwork, using 30 pounds of copper per day. Now, we are told, the factories at Phillipsdale cover three acres, consume 75,000 lbs. of copper daily, and give employment to 700 people. There is also a factory at Montreal where 100 hands are at work.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

(Issued by the Washington Carbon Company.)

JANUARY, 1896.

INCORPORATIONS.

The Sullivan Estate Company, San Francisco, Cal.—to deal in stocks, bonds and construct water works; generate electricity and electric and water power. Capital stock, $1,000,000. Promoters: Francis J. Sullivan, Chas. A. Sullivan, Ada E. Sullivan, Frances V. Sullivan, Geo. B. Sullivan, Henriette Sullivan, Emmet V. Sullivan, Belle S. Turner, Mary Piggott, San Francisco.

The Meadville and Saegertown Street Railway Company, Pittsburg, Pa.—to build an electric street railway in Meadville. Capital stock, $31,000. Promoters: Geo. D. Trawin, H. H. Thompson, F. R. Shryock, Meadville, Pa.

The Latrobe and Ligonier Electric Street Railway Company, Latrobe, Pa.—to build an electric street railway in Westmoreland County, Pa., from Latrobe to Ligonier, a distance of 12 miles. Capital stock, $72,000. Promoters: Ed. E. Robbins, John E. Kunkle, Harry N. Yout, Greensburg, Pa.

The Electric Railway Switch and Supply Company, Saco, Maine—to manufacture and deal in electric railway motor and station switches. Capital stock, $100,000. Promoters: Leonard L. Davis, Edgar Tanner, Springfield, Mass.; Ambrose Eastman, Boston, Mass.

The O'Brien Electrical Construction Company, Bloomfield, N. J.—to construct, maintain and operate electric light, power and signal and electric elevator apparatus. Capital stock, $100,000. Promoters: Jas. P. O'Brien, Philip J. O'Brien, New York City; Daniel J. O'Keeffe, Bloomfield, N. J.

The Saegertown and Venango Street Railway Company, Pittsburg, Pa.—to build an electric street railway in Saegertown, Crawford County, Pa. Capital stock, $72,000. Promoters: Geo. D. Trawin, H. H. Thompson, F. R. Shryock, Meadville, Pa.

The Keystone Boiler Works, San Francisco, Cal.—to deal in patents, patent rights, stocks, bonds; manufacture machinery, ships and water crafts of all kinds: construct foundries, machine and boiler shops, all kinds of railways, cable roads, electric roads and bridges. Capital stock, $200,000. Promoters: Jas. Hamilton, John J. More, John V. Hunter, San Francisco, Cal.; Wm. Leach and Jas. M. Robinson, Oakland, Cal.

The Empire City Traction Company—to operate a street railway in the upper part of New York City. Capital stock, $100,000. Directors: H. L. Scheuerman, F. H. Knight, E. M. Johnson, B. F. Defreee, F. W. Elder, M. J. Katz, H. W. Mayer and Homer Scoville, of New York, and Samuel Slater, of Arlington, N. J.

The Fredericktown Electric and Manufacturing Company, of Fredericktown, Mo., has increased its capital stock from $6,000 to $25,000.

The Electric and Steam Appliance Company, Jersey City, N. J.—to conduct a general mechanical engineering business and manufacture and deal in machinery of all kinds, including valves and electrical and mechanical controlling devices. Capital stock, $500,000. Incorporators: Alfred Luthnan, New York; Edward J. Maturin, Jersey City, and Herbert Hatch, East Orange, N. J.

The Millbrook Electric Light Company, Ltd., Millbrook, Can.—to carry on the business of the present Millbrook Electric Light Company. Capital, $6,500. Incorporators: J. C. Kells, J. A. Vance, R. J. Doak, W. T. Wood, Dr. H. A. Turner, A. A. Smith and A. Leach of Millbrook, and S. G. Parkin, of Lindsay, Can.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 31, 1895.

ELECTRIC RAILWAYS AND APPLIANCES.

552,338. Electrical Rail-Fish. Victor Thelin, Geneva, Switzerland, assignor to the Compagnie de l'Industrie Electrique, same place. Filed Aug. 1, 1895.

552,347. Motor-Suspension for Street-Cars. George F. Card, Mansfield, O. Filed Aug. 21, 1895.

552,369. Means for Operating Electric Railway-Vehicles. Ernst G. W. C. Hoffmann, Charlottenburg, Germany assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Sept. 8, 1895.

552,451. Electric Railway. Michael H. Smith, Halifax, England. Filed Oct. 26, 1887.

552,477. Rail-Bond for Electric Railways. Budd J. Jones, Chicago, Ill. Filed March 29, 1895.

552,479. Electrical Rail-Bond. Minott K. Kendall, Melrose, assignor of two-thirds to Gilbert Hodges, Medford, and Ephraim Harrington, Boston, Mass. Filed Aug. 12, 1895.

552,486. Car-Brake. Alexander B. Roney, Chicago, Ill., assignor to Philip Opper, same place. Filed Dec. 8, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

552,190. Electric-Arc Light. Louis B. Marks, New York, N. Y., assignor to the Electric Arc Light Company, same place. Filed Oct. 9, 1894.

552,371. Method of and Apparatus for Measuring Illumination. Edwin J Houston and Arthur E. Kennelly, Philadelphia, Pa. Filed Feb. 13, 1895.

552,384. Electric Gas-Lighter. Philip Meyer, Alameda, Cal. Filed Sept. 20, 1895.

552,495. Regulator for Electrical Circuits. Joseph C. Mayrhofer, New York, N. Y., assignor to Denman Thompson, West Swanzey, N. H. Filed July 5, 1895.

552,496 Electric-Lighting System. Joseph C. Mayrhofer, New York, N. Y., assignor to Denman Thompson, West Swanzey, N. H. Filed July 5, 1895.

552,498. Electric-Arc Incandescent Lamp. John A. Mosher, Chicago, Ill. Filed Sept. 23, 1895.

DYNAMO ELECTRIC MACHINERY, ETC.

552,103. Multipolar Electromagnet. William P. Daniels, Cologne, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Sept. 7, 1895.

552,105. Apparatus for Automatically Maintaining Current Upon Moving Vehicles. Harry E. Dey, Brooklyn, assignor to Edward N. Dickerson and Ernest R. Esmond, New York, N. Y. Filed May 20, 1895.

552,172. Electro-magnetic Mechanism. Stephen D. Field, Stockbridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed Aug. 5, 1895.

552,260. Apparatus for Transforming Alternating Currents into Unidirectional Currents. Carl Pollak, Frankfort-on-the-Main, Germany. Filed May 22, 1893.

552,313. Synchronous Single-Phase Motor. Charles E. L. Brown, Baden, Switzerland. Filed Feb. 6, 1893.

552,337. Electric Motor. Albert W. Smith, Washington, D. C. Filed July 23, 1895.

552,397. Regulator for Dynamos. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 1, 1889.

TELEPHONE AND TELEGRAPH APPARATUS.

552,173. Electric Telephone. Stephen D. Field, Stockbridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed Aug. 5, 1895.

552,420. Signaling and Lock-Out Apparatus for Telephone-Stations. John D. Clarke, Chicago, Ill., assignor to the American Bell Telephone Company, Boston, Mass. Filed April 5, 1895.

552,469. Double-Diaphragm Telephone-Transmitter. Dan'l Drawbaugh, Eberly's Mill, assignor to G. Milton Bair, Hanover, and Calvin W. Ream, Reading, Pa. Filed Feb. 23, 1895.

BATTERIES.

552,211. Depolarizer for Primary Batteries and Method of Making Same. Gustav W. Thurnauer, Aurora, and Milton M. Kohn, Chicago, assignors to themselves and Siegfried M. Fischer, Chicago, Ill. Filed Feb. 20, 1895.

552,219. Electrical Battery. David S. Williams, Philadelphia, Pa. Filed Aug. 23, 1895.

552,218. Electric Battery. David S. Williams, Philadelphia, Pa. Filed July 19, 1895.

552,220. Electric Battery. David S. Williams, Philadelphia, Pa. Filed Aug. 23, 1895.

552,322. Secondary Battery. Alvaro S. Krotz and Wilbur W. Spencer, Springfield, O. Filed Jan. 31, 1895.

552,425. Secondary Battery. Camille A. Faure, Paris, France, and Frank King, London, England Filed March 6, 1895.

SIGNALS AND SIGNALING APPARATUS.

552,181. Electrical Railway Signaling Apparatus. Henry J. Hovey, Evanston, Ill. Filed Aug. 5, 1895.

552,279. Electric Signal for Railways. Elisha B. Cutten, New York, assignor to Arthur C. Fraser and George H. Fraser, Brooklyn, N. Y. Filed April 1, 1891.

552,316. Electrical Railway Signaling System. Thomas B. Dixon, Henderson, Ky. Filed July 10, 1894.

MISCELLANEOUS.

552,094. Automatic Electric Switch. Harry H. Blades, Detroit, Mich. Filed Sept. 14, 1895.

552,153. Keyless Fire-Alarm-Telegraph Box. Nathan H. Suren, New York, N. Y., assignor to The Gamewell Fire-Alarm Telegraph Company, same place. Filed March 8, 1895.

552,'66. Electric Thermostat and Push-Button. Orator F. Woodward, Le Roy, N. Y. Filed Dec. 29, 1893.

552,239. Safety Device for Electric Circuits. Paul H. D'Unger, Chicago, Ill., assignor of one-half to William Porter Verity, same place. Filed Sept. 16, 1895.

552,271. Electrical Bicycle. Ogden Bolton, Jr., Canton, O. Filed Sept. 19, 1895.

552,309. Electric Meter. John R. Tucker and Charles C. Hinckley, Aurora, Ill. Filed March 25, 1895.

552,341. Electric Smelting-Furnace. Joseph A. Vincent and James E. Hewes, Philadelphia, Pa. Filed July 18, 1895.

552,363. Insulating-Joint. Elliott P. Gleason, Brooklyn, assignor to the E. P. Gleason Manufacturing Company, New York, N. Y. Filed Dec. 27, 1894.

552,414. Galvanic Feed-Water Purifier. Samuel G. Cabell, Washington, D. C. Filed Oct. 16, 1895.

552,501. Insulator. Charles H. Snivley, Mount Carmel, Pa. Filed March 20, 1895.

DESIGNS.

25,028. Box for Electric Motors. Arthur W. Browne, Prince's Bay, N. Y., assignor to the S. S. White Dental Manufacturing Company, Philadelphia, Pa. Filed Oct. 12, 1895. Term of patent 14 years.

25,032. Frame for Dynamo-Machines. Clinton E. Woods, Chicago, Ill. Filed June 11, 1894. Term of patent 14 years.

25,033. Frame for Electric Motors, etc. Dugald C. Jackson and Conrad M. Conradson, Madison, Wis. Filed July 26, 1895. Term of patent 7 years.

BUCKEYE Incandescent LAMPS.

——Quality Unequalled.——

THE BUCKEYE ELECTRIC COMPANY, Cleveland, Ohio.

Monadnock Building, Chicago.

IMPORTANT ANNOUNCEMENT.

We have employed as Superintendent, *MR. A. L. REINMANN, formerly Superintendent of the Sawyer-Man Electric Co.* His ability is known to everybody in the electric light business. Recent improvements made by him, added to the qualities which have already given our lamps such an enviable reputation, easily make the

American Incandescent Lamps

THE HIGH GRADE STANDARD OF THE WORLD.

Quality will tell, and we invite comparisons and tests. Write to us before placing your orders.

AMERICAN ELECTRICAL MAN'F'G CO.,

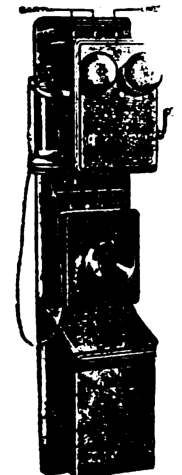
Long-Distance Dust Transmitter.



Complete Telephone.

Patented in England and America.

The Original Powder Transmitter and the only one adopted by the English Post Office for public long-distance service all over Great Britain. You can shout in it or whisper in it and get perfect articulation in either case. No limit to the distance they will work.

Claim No 1 of the "Hunnings" Patent "is in a tension-regulator or means for varying the resistance in a telephone transmitter, finely divided conducting material in a loose and free state."

THE "HUNNINGS"

DUST TRANSMITTER

Does not depend upon variable pressure between electrodes in constant contact. **Incorporated as a portion of the Electric Circuit** is a quantity of finely divided conducting material or dust, the movement of which varies the current.

We are the only Manufacturers in the United States of the Celebrated "Hunnings" English Transmitter.

Several large exchanges are now using our "Hunnings" Outfit.

AMERICAN ELECTRIC TELEPHONE CO.,
Kokomo, Ind., U. S. A.

In advertising you seek the buyers and users of goods. Electricity reaches them.

TALKS FOR CENTRAL STATIONS.

VII. HAVE you ever pondered on the desirability of keeping closer track on the life of your lamps, and giving the manufacturers to understand that you would measure random selections from each lot? If you did you might get better results. Poor lamps are plentiful by your tolerance. Take the delinquents to task. If you do it will result beneficially. A report recently made by a German Commission, who investigated the different German lamps, showed that lamps called 16 C. P. ran all the way from 7 to 23 candle, and in efficiency were as low as 6.3 watts per candle. Poor American lamps are fully as bad. No Station can operate economically, no matter what grade of machinery is employed, if the total saving is lost many times over in the lamps.

We can refer to Stations using our 3-watt lamps, whose burn-outs average but two per cent. per month. Give us your inquiries.

1896. **1896.**

Siemens & Halske Electric Company of America.

Siemens & Halske: Berlin, Charlottenburg, Vienna, St. Petersburg.

MANUFACTURERS OF

Direct Current Slow Speed Multipolar Generators and Motors.

These machines are constructed with *external armatures.* They have proved remarkably efficient and economical. Used largely in American and European Lighting and Railway Plants. Slow-speed machines, made for direct connection in sizes from 20 H. P. to 2,000 H. P.

ADVANTAGES OF OUR EXTERNAL ARMATURE TYPE:

Maximum peripheral speed of armature with slowest engine speed. Shortest possible winding of armature. Lowest internal resistance of armature.
Only 8 to 4 volts difference of potential between commutator bars. Greatest radiating surface possible. Maximum magnetic effect.
Greatest weight of copper per ampere of current. Armatures cannot burn out. Great compactness.
Correct mechanical design. (The centrifugal force is counteracted effectively by the inward pull of the internal field magnets.)
Finest quality of iron, excellent finish, absence of binding wire.

In 8 years' continuous service not one Armature has been replaced or repaired. **Over 200,000 H. P. in use for Railway, Lighting and Motor Service.**

WORLD'S FAIR DIPLOMA AND MEDAL FOR BEST DIRECT CONNECTED GENERATOR.

MODERATE SPEED BIPOLAR GENERATORS AND MOTORS,

With Siemens Drum Armatures, which are copied extensively in this country. We are building these machines in sizes from 1 H. P to 150 H. P.

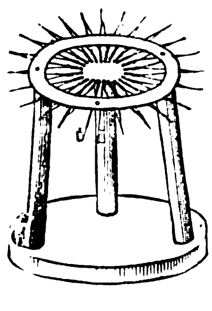
Electrical Instrument Making for Amateurs. By S. R. Bottone. Contains plain instructions by help of which any one with an ordinary knowledge of English, and moderately handy with tools, can make for his own entertainment, or for use in the study of a great science, all the instruments now employed in theoretical or practical Electricity, from Torsion Balances, Holtz Machines and Induction Coils to Dynamos, Electric Motors, Telephones, Phonographs and Micrographs; and all the experiments of the great leaders in these studies, Wheatstone, Bell, Preece, Hughes, and Edison, can, after an attentive perusal of this book, be understood and repeated. 200 pages, cloth, postpaid......75 cts.

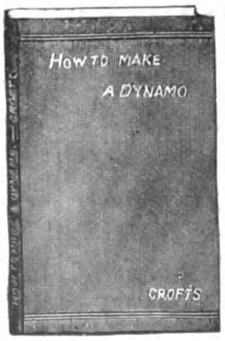


HOW TO MAKE A DYNAMO.

By Alfred Crofts.

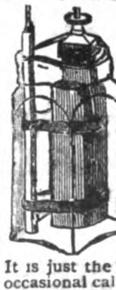
A practical work for Amateurs and Electricians, containing numerous illustrations and detailed instructions for constructing Dynamos of all sizes, to produce the Electric Light, containing 96 pages of genuine information which will enable anyone to construct a Dynamo either for pleasure or profit.

Large 12 mo, Cloth, 75 Cts.



Electric Bells, and all about them.—S. R. Bottone. 196 pages, 100 illustrations.

In this volume the whole subject of Electric Bells is explained in simple language. Any one with an English education can master it in a few hours. The illustrations are great helps to understanding the descriptions. The work begins by showing how the force applied to Electric Bells is produced, and goes on to tell how to arrange every kind of signal which can be given by electricity, as well as all needed information that belongs to the subject. It is just the book needed by mechanics who have occasional calls upon them to mount bells, and Bell-Hangers, Locksmiths, etc., who are not yet acquainted with all the uses of the Electric Bell. Cloth......75 cts.



Electro-Motors; How Made and How Used.—A handbook for Amateurs and Practical Men by S. R. Bottone and A. M. A. Beale.—A complete and simple explanation of the source of the power in a dynamo and the method of applying the same, commencing with a Simple Motor, and proceeding to an exposition of the Siemen's, Thompson's, Walker's, Grison and other motors.

In addition three special chapters by an American author follow in which the information embraces all American improvements. The work is probably the most complete and easily understood of any published.

180 Pages, Cloth, price..........75 Cts.

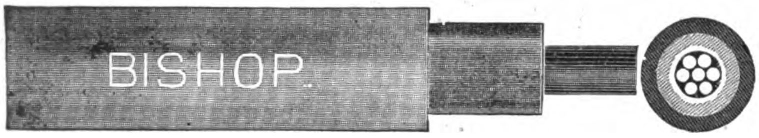
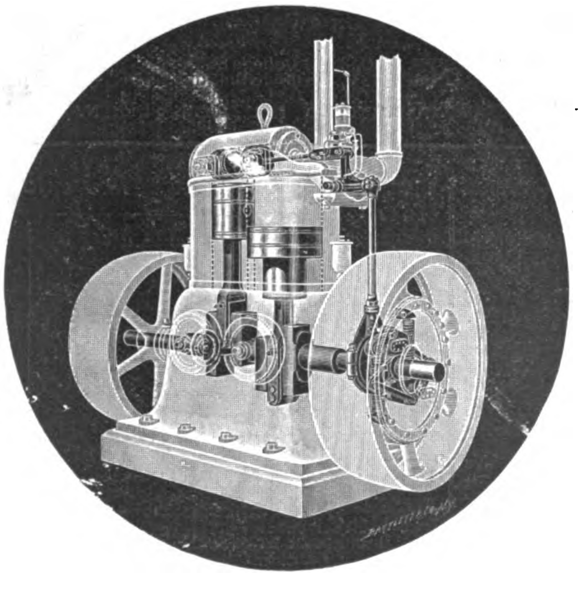
In Insulated Wires——



BISHOP MEANS **BEST.**

We make no "white ravens," "red bluejays" or "blue-red tangiers." If you buy cheap rubber shoes or hose and they don't last they are easily replaced. If your rubber insulation caves in, the undertaker may get a job, or the insurance companies may pay part of the damage. Does it pay to take the risk?

BISHOP GUTTA PERCHA COMPANY,
Factory and Office: 420-426 East 25th Street, New York.



Steam Power Plants of High Efficiency

——ARE EQUIPPED WITH——

WESTINGHOUSE ENGINES.

THREE TYPES.

COMPOUND, 35 to 1,000 H. P.	Unequalled adaptability, high fuel duty and moderate cost.
STANDARD, 5 to 250 H. P.	High-class automatic engine for general service.
JUNIOR, 5 to 75 H. P.	A durable and efficient automatic engine at a low price.

CATALOGUE ON APPLICATION.

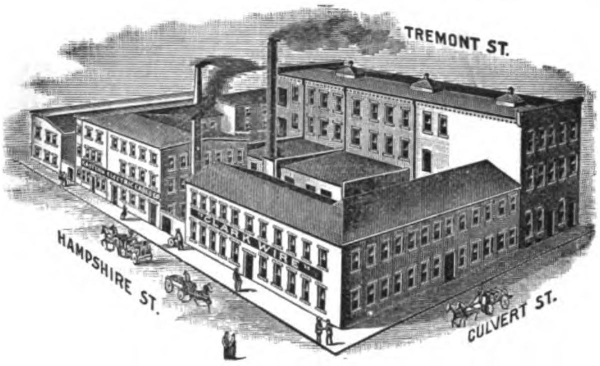
THE "CLARK" WIRE.

In a Letter from the Inspector of the Boston Fire Underwriters' Union, he states: . . . .

"A Thoroughly Reliable and Desirable Wire in Every Respect."



TREMONT ST.
HAMPSHIRE ST.
CULVERT ST.

For Switchboard, Railway and Motor Use, we make all sizes of Stranded and Flexible Wire and Cables with Clark's insulation.

The Clark Wire has been before the public and in use for the past nine years, and has met with universal favor. Thousands of miles of this wire have been sold, and are in use throughout the United States and Foreign Countries, and the demand for it is constantly increasing because it always gives perfect satisfaction.

The Rubber used in insulating our Wires and Cables is especially chemically prepared and will not deteriorate, oxidize or crack, and will remain flexible in extreme cold weather and is not affected by heat.

We guarantee our Insulation wherever used, Aerial, Underground or Submarine, and our net prices are as low, if not lower, than any other first-class insulated Wire.

We shall be pleased to mail Catalogues with Terms and Discounts for Quantities.

AMERICAN ELECTRICAL CASES.

A CURRENT SERIES.

Edited by WM. W. MORRILL. Published by MATTHEW BENDER, Albany, N. Y.

Vols. 1, 2 and 3 of the series have been published and have met with a reception that fully justifies the publisher in permanently continuing the series, the scope of which is to broadly cover all electrical cases coming before the courts in all sections of the country.

In Vol. 2 there were 180 cases, and of these 69 pertain to the duties and liabilities of telegraph companies as carriers of news. In Vol. 3 the telegraph cases number 42.

The subject of Interference of Electrical Currents, usually made prominent in actions brought by telephone companies whose weaker currents are unfavorably affected by the powerful currents used by light and power companies, is represented by one case in Vol. 1, two cases in Vol. 2, and ten cases in Vol. 3.

The RIGHTS OF ABUTTING OWNERS, as affected by the maintenance of electrical apperatus in highways, are considered in six cases in Vol. 2, while in Vol. 3 there are eighteen upon that subject.

In Vol. 3 Telegraph Companies were concerned in sixteen cases, Electric Light Companies in eighteen, Telephone Companies in twenty, and Electric Railway Companies in twenty-five, or nearly one-fourth the whole number of cases in the volume, a surprising proportion when we recall how recently the electric railway first came into use.

The subject being of such practical and increasing importance in its legal aspects, the convenience and even necessity of keeping abreast of it must be evident to the profession.

Vols. 1, 2 and 3 are now ready. They are handsome books, bound in full leather, well annotated and thoroughly indexed. Price per volume, $6.00.

Modern Examinations of Steam Engineers,

OR

Practical Theory Explained and Illustrated.

BY W. H. WAKEMAN.

12mo. Cloth. 300 Pages. 58 Chapters.

Containing a complete list of 300 questions such as will be asked of any Engineer when taking examination for U. S. Government or State License, all of which are fully answered in the text.

Price $2.00

By mail, postpaid, to any part of the world.

This book while especially adapted for engineers' examinations is also intended as a practical guide to Engineers, Firemen, Boiler Makers, Machinists, and others, in daily practice.

The author being a practical steam engineer himself, well knows the wants of the working engineer, and has put into this work such knowledge and information as is best adapted to their use, making it altogether the most complete and comprehensive guide for the busy workers in the engine room, boiler works and machine shops that has ever been published.
